

The Collected Works of Ludwig Wittgenstein

All texts copyright © Blackwell Publishers

1. CONTENTS. To view the complete table of contents of **The Collected Works of Ludwig Wittgenstein**, click on the **Contents** icon on the left border of your screen. Click on plus (+) symbols in the Contents window to expand the list of entries. A minus symbol (-) indicates that a list may not be further expanded. While viewing the contents, click on **Levels** under the **Search** menu to view the Contents at the Book, Chapter, Section (etc.) levels. While in the Contents window, you may jump to any location by double-clicking on the line of interest or click on the **Contents** icon to go back to full database view.

2. SEARCH TEXT. To execute a search, click on the **Query** icon on the left border of your screen, type in your search terms in the **Query For:** window, then click on **OK** to execute your search. The page number of each paragraph and page break is given in the text; click on **Hidden** under the **View** menu to also view an abbreviation identifying the work. Two query templates have been provided under the search menu to enable searches of particular works, or to permit jumping to a particular page of a work.

PREFACE TO THE SECOND EDITION

Page 1

THE text of this volume has been completely revised for this edition, and a number of misreadings have been corrected. These were mostly very small. The most serious one that I have found was the reading of "u.u." ("und umgekehrt") as "u.U" ("unter Umständen"). The diagram on p. 126 has been corrected in accordance with the MS.

Page 1

The second appendix, *Notes on Logic* 1913, appears here in a different arrangement from that of the first edition. That edition used the text published in the *Journal of Philosophy* (Vol. LIV (1957), p. 484) by J. J. Costelloe: he reported having got it from Bertrand Russell in 1914. There was a different text which the editors had, and which they had also got from Russell. It was clear that the Costelloe version was a slightly corrected total rearrangement of that text under headings, and we assumed that it had been made by Wittgenstein himself.

Page 1

A debt of gratitude is owing to Brian McGuinness, not only for having pointed out some errors of transcription in the first edition, but also for having proved that the Costelloe version was constructed by Russell. The other one is therefore closer to Wittgenstein, the first part of it being his own dictation in English and the rest a translation by Russell of material dictated by Wittgenstein in German. Mr. McGuinness' article giving the evidence for this can be found in the *Revue Internationale de Philosophie*, no. 102 (1972).

Page 1

In the first edition a number of passages of symbolism, in one case with accompanying text, were omitted because nothing could be made of them: they were presumably experimental, but it seemed impossible to interpret them. Nor would it always have been clear what was an exact transcription of them. Photographs of them are printed here as a fourth appendix.

Page 1

At the 20th of December 1914 there was a rough line of adjacent crayonned patches, using 7 colours. This was treated as a mere doodle in the first edition, and so it may be. But, having regard to the subject matter of meaning and negation, which is the topic of the surrounding text, it is possible that there is here an anticipation of *Philosophical Investigations* § 48. A representation of it is printed on the dust cover of this edition.

Page Break 2

[Notebooks: Main Body]

Page 2

Logic must take care of itself. [See 5.473.]

Page 2

If syntactical rules for functions can be set up *at all*, then the whole theory of things, properties, etc., is superfluous. It is also all too obvious that this theory isn't what is in question either in the *Grundgesetze*, or in *Principia Mathematica*. Once more: logic must take care of itself. A *possible* sign must also be capable of signifying. Everything that is possible at all, is also legitimate. Let us remember the explanation why "Socrates is Plato" is nonsense. That is, because *we* have not made an arbitrary specification, NOT because a sign is, shall we say, illegitimate in itself! [Cf. 5.473.]

2.9.14.

Page 2

It must in a certain sense be impossible for us to go wrong in logic. This is already partly expressed by saying: Logic must take care of itself. This is an extremely profound and important insight. [Cf. 5.473.]

Page 2

Frege says: Every well-formed sentence must make sense; and I say: Every possible sentence is well-formed, and if it does not make sense that can only come of our not having *given* any meaning to certain of its parts. Even when we believe we have done so. [Cf. 5.4733.]

3.9.14.

Page 2

How is it reconcilable with the task of philosophy, that logic should take care of itself? If, for example, we ask: Is such and such a fact of the subject-predicate form?, we must surely know what we mean by "subject-predicate form". We must know *whether* there is such a form at all. How can we know this? "From the signs". But how? For we haven't got any *signs* of this form. We may indeed say: We have signs that behave like signs of the subject-predicate form, but does that mean that there really must be facts of this form? That is, when those signs are completely analysed? And here the question arises again: Does such a complete analysis exist? *And if not*: then what is the task of philosophy?!?

Page 2

Then can we ask ourselves: Does the subject-predicate form exist? Does the relational form exist? Do any of the forms exist at all that

Page Break 3

Russell and I were always talking about? (Russell would say: "Yes! that's self-evident." *Ha!*)

Page 3

Then: if *everything* that needs to be shewn is shewn by the existence of subject-predicate SENTENCES etc., the task of philosophy is different from what I originally supposed. But if that is not how it is, then what is lacking would have to be shewn by means of some kind of experience, and that I regard as out of the question.

Page 3

The obscurity *obviously* resides in the question: what does the logical identity of sign and thing signified really consist in? And this question is (*once more*) a main aspect of the whole philosophical problem.

Page 3

Let some philosophical question be given: e.g., whether "A is good" is a subject-predicate proposition; or whether "A is brighter than B" is a relational proposition. *How can such a question be settled at all?* What sort of evidence can satisfy me that--*for example*--the first question must be answered in the affirmative? (This is an extremely important question.) Is the only evidence here once more *that extremely dubious "self-evidence"*? Let's take a question quite like that one, which however is simpler and more fundamental, namely the following: Is a point in our visual field a *simple object*, a *thing*? Up to now I have always regarded such questions as the real philosophical ones: and so for sure they are in some sense--but once more what evidence could settle a question of this sort at all? Is there not a mistake in formulation here, for it looks as if *nothing at all* were self-evident to me on this question; it looks as if I could say definitively that these questions could never be settled at all.

4.9.14.

Page 3

If the existence of the subject-predicate *sentence* does not show everything needful, then it could surely only be shewn by the existence of some particular fact of that form. And acquaintance with such a fact cannot be essential for logic.

Page 3

Suppose we had a sign that *actually* was of the subject-predicate form, would this be somehow better suited

to express subject-predicate propositions than our subject-predicate sentences are? It seems not! Does this arise from the signifying relation?

Page 3

If logic can be completed without answering certain questions, then it *must* be completed *without* answering them.

Page 3

The logical identity between sign and thing signified consists in

Page Break 4

its not being permissible to recognize more or less in the sign than in what it signifies.

Page 4

If sign and thing signified were *not* identical in respect of their total logical content then there would have to be something still more fundamental than logic.

5.9.14.

Page 4

$$\phi(a). \phi(b). aRb = \text{Def } \phi[aRb]$$

Page 4

Remember that the words "function", "argument", "sentence" etc. ought not to occur in logic.

Page 4

To say of two classes that they are identical means something. To say it of two things means nothing. This of itself shews the inadmissibility of Russell's definition.

6.9.14.

Page 4

The last sentence is really nothing but the old old objection against identity in mathematics. Namely the objection that if 2×2 were really the *same* as 4, then this proposition would say no more than $a = a$.

Page 4

Could it be said: Logic is *not* concerned with the analysability of the functions with which it works.

7.9.14.

Page 4

Remember that even an unanalysed subject-predicate proposition is a clear statement of something *quite definite*.

Page 4

Can't we say: It all depends, not on our dealing with unanalysable subject-predicate sentences, but on the fact that our subject-predicate sentences behave in the same way as such sentences in *every* respect, i.e. that the logic of *our* subject-predicate sentences is the same as the logic of those. The point for us is simply to complete logic, and our objection-in-chief against unanalysed subject-predicate sentences was that we cannot construct their syntax so long as we do not know their analysis. But must not the logic of an apparent subject-predicate sentence be the same as the logic of an actual one? If a definition giving the proposition the subject-predicate form is possible at all...?

8.9.14.

Page 4

The "self-evidence" of which Russell has talked so much can only be dispensed with in logic if language itself prevents any logical mistake. And it is clear that that "self-evidence" is and always was wholly deceptive. [Cf. 5.4731.]

Page Break 5

19.9.14.

Page 5

A proposition like "this chair is brown" seems to say something enormously complicated, for if we wanted to express this proposition in such a way that nobody could raise objections to it on grounds of ambiguity, it would have to be infinitely long.

20.9.14.

Page 5

That a sentence is a logical portrayal of its meaning is obvious to the uncaptive eye.

Page 5

Are there functions of facts? e.g. "It is better for this to be the case than for that to be the case?"

Page 5

What, then, is the connexion between the sign p and the rest of the signs of the sentence "that p is the case, is good"? What does this connexion consist in?

Page 5

The uncaptive judgement will be: Obviously in the spatial relation of the letter p to the two neighbouring signs. But suppose the fact " p " were such as to contain no things?

Page 5

"It is good *that* p " can presumably be analysed into " p . it is good *if* p ".

Page 5

We assume: p is NOT the case: now what does it mean to say "that p , is good"? Quite obviously we can say that the situation p is good without knowing whether " p " is true or false.

Page 5

This throws light on what we say in grammar: "One word refers to another".

Page 5

That is why the point in the above cases is to say how propositions hang together internally. How the *propositional bond* comes into existence. [Cf. 4.221.]

Page 5

How can a function *refer to a proposition*???? Always the old old questions.

Page 5

Don't let yourself get overwhelmed with questions; just take it easy.

Page 5

" $\phi(\psi x)$ ": Suppose we are given a function of a subject-predicate proposition and we try to explain the way the function refers to the proposition by saying: The function only relates immediately to the subject of the subject-predicate proposition, and what signifies is the logical product of this relation and the subject-predicate propositional sign. Now if we say this, it can be asked: If you can explain the

Page Break 6

proposition like that, then why not give an analogous explanation of what it stands for? Namely: "It is not a function of a subject-predicate fact but the logical product of such a fact and of a function of its subject"? Must not the objection to the latter explanation hold against the former too?

21.9.14.

Page 6

Now it suddenly seems to me in some sense clear that a property of a situation must always be internal.

Page 6

$\phi a, \psi b, aRb$. It could be said that the situation aRb always has a certain property, if the first two propositions are true.

Page 6

When I say: It is good for p to be the case, then this must be good *in itself*.

Page 6

It now seems clear to me that there cannot be functions of situations.

23.9.14.

Page 6

It could be asked: How can the situation p have a property if it turns out that the situation does not hold at all?

24.9.14.

Page 6

The question how a correlation of relations is possible is identical with the problem of truth.

25.9.14.

Page 6

For the latter is identical with the question how the correlation of situations is possible (one that signifies and one that is signified).

Page 6

It is only possible by means of the correlation of the components; the correlation between names and things named gives an example. (And it is clear that a correlation of relations too takes place somehow.)

| aRb |; | $a b$ |; $p = aRb$ Def

Here a simple sign is correlated with a situation.

Page 6

What is the ground of our--certainly well founded--confidence that we shall be able to express any sense we like in our two-dimensional script?

27.9.14.

Page 6

A proposition can express its sense *only* by being the logical portrayal of it.

Page Break 7

Page 7

The similarity between these signs is striking:

"aRb"

"aσR.Rσb".

29.9.14.

Page 7

The general concept of the proposition carries with it a quite general concept of the coordination of proposition and situation: The solution to all my questions must be *extremely* simple.

Page 7

In the proposition a world is as it were put together experimentally. (As when in the law-court in Paris a motor-car accident is represented by means of dolls, etc.†1) [Cf. 4.031.]

Page 7

This must yield the nature of truth straight away (if I were not blind).

Page 7

Let us think of hieroglyphic writing in which each word is a representation of what it stands for. Let us think also of the fact that *actual* pictures of situations can be *right* and *wrong*. [Cf. 4.016.]

Page 7

"": If the right-hand figure in this picture represents the man A, and the left-hand one stands for the man B, then the whole might assert, e.g.: "A is fencing with B". The proposition in picture-writing can be true and false. It has a sense independent of its truth or falsehood. It must be possible to demonstrate everything essential by considering this case.

Page 7

It can be said that, while we are not certain of being able to turn all situations into pictures on paper, still we are certain that we can portray all *logical* properties of situations in a two-dimensional script.

Page 7

This is still very much on the surface, but we are on good ground.

30.9.14.

Page 7

It can be said that in our picture the right-hand figure is a representation of something and also the left-hand one, *but* even if this were not the case, their relative position could be a representation of something. (Namely a relation.)

Page Break 8

Page 8

A picture can present relations that do not exist! How is that possible?

Page 8

Now once more it looks as if all relations must be logical in order for their existence to be guaranteed by that of the sign.

2.10.14.

Page 8

What connects a and c in "aRb.bSc" is not the sign "." but the occurrence of the same letter "b" in the two simple sentences.

Page 8

We can say straight away: Instead of: this proposition has such and such a sense: this proposition represents such and such a situation. [See 4.031.]

Page 8

It portrays it logically.

Page 8

Only in this way can *the proposition* be true or false: It can only agree or disagree with reality by being a *picture* of a situation. [See 4.06.]

3.10.14.

Page 8

The proposition is a picture of a situation only in *so far* as it is logically articulated. (A simple-non-articulated-sign can be neither true nor false.) [Cf. 4.032.]

Page 8

The *name* is *not* a picture of the thing named!

Page 8

The proposition *only says something in so far* as far as it is a *picture*! [See 4.03.]

Page 8

Tautologies say nothing, they are not pictures of situations: they are themselves logically completely neutral. (The logical product of a tautology and a proposition says neither more nor less than the latter by itself.) [See 4.462 and 4.463.]

4.10.14.

Page 8

It is clear that "xRy" can contain the signifying element of a relation even if "x" and "y" do not stand for anything. And in that case the relation is the only thing that is signified in that sign.

Page 8

But in that case,†1 how is it possible for "kilo" in a code to mean: "I'm all right"? Here surely a *simple sign* does assert something and is used to give information to others.--

Page 8

For can't the *word* "kilo", with that meaning, be true or false?

Page Break 9

5.10.14.

Page 9

At any rate it is surely possible to correlate a simple sign with the sense of a sentence.--

Page 9

Logic is interested only in reality. And thus in sentences ONLY in so far as they are *pictures* of reality.

Page 9

But how CAN a SINGLE *word* be true or false? At any rate it cannot express the *thought* that agrees or does not agree with reality. That *must* be articulated.

Page 9

A single word cannot be true or false in *this* sense: it cannot agree with reality, or the opposite.

6.10.14.

Page 9

The general concept of two complexes of which the one can be the logical picture of the other, and so in one sense *is* so.

Page 9

The agreement of two complexes is obviously *internal* and for that reason cannot be expressed but can only be shewn.

Page 9

"p" is true, says nothing else but p.

Page 9

"p' is true" is--by the above--only a pseudo-proposition like all those connexions of signs which apparently say something that can only be shewn.

7.10.14.

Page 9

If a proposition ϕa is given, then all its logical functions ($\sim\phi a$, etc.) are *already* given with it! [Cf. 5.442.]

Page 9

Complete and incomplete portrayal of a situation. (Function plus argument is portrayed by function plus argument.)

Page 9

The expression "not further analysable" too is one of those which, together with "function", "thing" etc. are on the Index; but how does what we try to express by means of it get *shewn*?

Page 9

(Of course it cannot be said either of a thing or of a complex that it is not further analysable.)

9.10.14.

Page 9

If there were such a thing as an immediate correlation of relations, the question would be: How are the things that stand in these relations correlated with one another in this case? Is there such a thing as a direct correlation of relations without consideration of their *direction*?

Page Break 10

Page 10

Are we misled into assuming "relations between relations" merely through the apparent analogy between the expressions:

"relations between things"
and "relations between relations"?

Page 10

In all these considerations I am somewhere making some sort of FUNDAMENTAL MISTAKE.

Page 10

The question about the possibility of existence propositions does not come in the middle but at the very first beginning of logic.

Page 10

All the problems that go with the Axiom of Infinity have already to be solved in the proposition " $(\exists x)x = x$ ". [Cf. 5.535.]

10.10.14.

Page 10

One often makes a remark and only later sees *how* true it is.

11.10.14.

Page 10

Our difficulty now lies in the fact that to all appearances analysability, or its opposite, is not reflected in language. That is to say: We can *not*, as it seems, gather from language alone whether for example there are real subject-predicate facts or not. But how COULD we *express* this fact or its opposite? *This must be shewn.*

Page 10

But suppose that we did not bother at all about the question of analysability? (We should then work with signs that do not stand for anything but merely *help* to express by means of their logical properties.) For even the unanalysed proposition mirrors logical properties of its meaning. Suppose then we were to say: The fact that a proposition is further analysable is shewn in our further analysing it by means of definitions, and we work with it in every case exactly as if it were unanalysable.

Page 10

Remember that the "propositions about *infinite* numbers" are all represented by means of *finite* signs.

Page 10

But do we not--at least according to Frege's method--need 100 million signs in order to define the number 100,000,000? (Doesn't this depend on whether it is applied to classes or to things?)

Page 10

The propositions dealing with infinite numbers, like *all* propositions of logic, can be got by calculating the signs themselves (for at no point does a foreign element get added to the original primitive signs). So

Page Break 11

here, too, the signs must themselves possess all the logical properties of what they represent.

12.10.14.

Page 11

The trivial fact that a completely analysed proposition contains just as many names as there are things contained in its reference; this fact is an example of the all-embracing representation of the world through language.

Page 11

It would be necessary to investigate the definitions of the cardinal numbers more exactly in order to understand the real sense of propositions like the Axiom of Infinity.

13.10.14.

Page 11

Logic takes care of itself; all we have to do is to look and see how it does it. [Cf. 5.473.]

Page 11

Let us consider the proposition: "there is a class with only one member". Or, what comes to the same thing, the proposition:

$$(\exists \phi) : (\exists x) : \phi x : \phi y . \phi z . \dot{E}_{y,z} y = z$$

Page 11

If we take " $(\exists x)x = x$ " it might be understood to be tautological since it could not get written down at all if it were false, but here! *This* proposition can be investigated in place of the Axiom of Infinity.

Page 11

I know that the following sentences as they stand are nonsensical: Can we speak of numbers if there are only things? I.e. if for example the world only consisted of one thing and of nothing else, could we say that there was ONE thing? Russell would probably say: If there is one thing then there is also a function $(\exists x) \overset{\Delta}{\xi} = x$. But!---

Page 11

If this function does not do it then we can only talk of 1 if there is a material function which is satisfied only by one argument.

Page 11

How is it with propositions like:

$$(\exists \phi) . (\exists x) . \phi(x) .$$

and $(\exists \phi) . (\exists x) . \sim \phi(x) .$

Is one of these a tautology? Are these propositions of some science, i.e. are they *propositions* at all?

Page 11

But let us remember that it is the *variables* and *not* the sign of generality that are characteristic of logic.

14.10.14.

Page 11

For is there such a thing as a science of completely generalized propositions? This sounds extremely improbable.

Page Break 12

Page 12

This is clear: If there are completely generalized *propositions*, then their sense does not depend on any arbitrary formation of signs! In that case, however, such a connexion of signs can represent the world only by means of its own logical properties, i.e. it can not be false, and not be true. So there are no completely generalized propositions. But now the application)

Page 12

But now the propositions: " $(\exists \phi, x) . \phi(x)$ "
and " $\sim (\exists \phi, x) . \phi(x)$ ".

Which of these is tautological, which contradictory?

Page 12

We keep on needing a comparative arrangement of propositions standing in internal relations. This book might well be equipped with diagrams.

Page 12

(The tautology *shews* what it appears to *say*, the contradiction *shews* the *opposite* of what it appears to say.)

Page 12

It is clear that we can form all the completely general propositions that are possible at all as soon as we are merely given *a language*. And that is why it is scarcely credible that such connexions of signs should really say anything about the world. On the other hand, however, this gradual transition from the elementary proposition to the completely general one!

We can say: The completely general propositions can all be formed *a priori*.

15.10.14.

Yet it does *not* look as if the mere existence of the forms contained in " $(\exists x, \phi). \phi(x)$ " could *by itself* determine the truth or falsehood of this proposition! So it does not appear *unthinkable* that, e.g., the negation of no elementary proposition should be true. But would not this statement itself touch the *SENSE of negation*?

Obviously we can conceive every quite general proposition as the affirmation or negation of the existence of some kind of facts. But does this not hold of all propositions?

Every connexion of signs which appears to say something about its own sense is a pseudo-proposition (like all propositions of logic).

The proposition is supposed to give a logical model of a situation. It can surely only do this, however, because objects have been arbitrarily correlated with its elements. Now if this is not the case in the

quite general proposition, then it is difficult to see how it should represent anything outside itself.

In the proposition we--so to speak--arrange things *experimentally*, as they do *not* have to be in reality; but we cannot make any *unlogical* arrangement, for in order to do that we should have to be able to get outside logic in language.--But if the quite general proposition contains *only* "logical constants", then it cannot be anything more to us than--simply--a logical structure, and cannot do anything more than shew us its own logical properties. If there are quite general propositions--*what* do we arrange experimentally in them? [Cf. 4.031 and 3.03.]

When one is frightened of the truth (as I am now) then it is never the *whole* truth that one has an inkling of.

Here I regarded the relations of the elements of the proposition to their meanings as feelers, so to say, by means of which the proposition is in contact with the outer world; and the generalization of a proposition is in that case like the drawing in of feelers; until finally the completely general proposition is quite isolated. But is this picture right? (Do I really draw a feeler in when I say $(\exists x). \phi x$ instead of ϕa ?) [Cf. 2.1515.]

16.10.14.

Now, however, it looks as if exactly the same grounds as those I produced to shew that " $(\exists x, \phi). \phi x$ " *could* not be false would be an argument shewing that " $\sim(\exists x, \phi). \phi x$ " could not be false; and here a fundamental mistake makes its appearance. For it is quite impossible to see why just the first proposition and not the second is supposed to be a tautology. But do not forget that the contradiction " $p. \sim p$ " etc. etc. cannot be true and is nevertheless itself a logical structure.

Suppose that no negation of an elementary proposition is true, has not "negation" another sense in this case than in the opposite case?

" $(\exists \phi): (x). \phi x$ "--of this proposition it appears almost certain that it is neither a tautology nor a contradiction. Here the problem becomes extremely sharp.

17.10.14.

If there are quite general propositions, then it looks as if such propositions were experimental combinations of "logical constants".(!)

But is it not possible to describe the whole world completely by means of completely general propositions? (The problem crops up on all sides.)

Yes, the world could be completely described by completely general propositions, and hence without using any sort of names or other denoting signs. And in order to arrive at ordinary language one would only need to

introduce names, etc. by saying, after an " $(\exists x)$ ", "and this x is A" and so on. [Cf. 5.526.]

Page 14

Thus it is possible to devise a picture of the world without saying what is a representation of what.

Page 14

Let us suppose, e.g., that the world consisted of the things A and B and the property F, and that $F(A)$ were the case and not $F(B)$. This world could also be described by means of the following propositions:

Page 14

$(\exists x,y).(\exists \phi).x \neq y.\phi x.\sim \phi y:\phi u.\phi z. \dot{E}_{u,z}.u = z$

$(\exists \phi).(\psi).\psi = \phi$

$(\exists x,y).(z).z = x \vee z = y$

And here one also needs propositions of the type of the last two, only in order to be able to identify the objects.

Page 14

From all this, of course, it follows that *there are completely general propositions!*

Page 14

But isn't the first proposition above enough: $(\exists x,y,\phi)\phi x.\sim \phi y.x \neq y$? The difficulty of identification can be done away with by describing the whole world in a single general proposition beginning: " $(\exists x,y,z... \phi,\psi... R,S...)$ " and now follows a logical product, etc.

Page 14

If we say " ϕ is a unit function and $(x).\phi x$ ", that is as much as to say: There is only one thing! (By this means we have *apparently* got round the proposition $(\exists x)(y).y = x$.)

18.10.14.

Page 14

My mistake obviously lies in a false conception of logical portrayal by the proposition.

Page 14

A statement cannot be concerned with the logical structure of the world, for in order for a statement to be possible at all, in order for a proposition to be CAPABLE of making SENSE, the world must already have just the logical structure that it has. The logic of the world is prior to all truth and falsehood.

Page Break 15

Page 15

Roughly speaking: before any proposition can make sense at all the *logical* constants must have reference. †1

19.10.14.

Page 15

The description of the world by means of propositions is only possible because what is signified is not its own sign! Application--.

Page 15

Light on Kant's question "How is pure mathematics possible?" through the theory of tautologies.

Page 15

It is obvious that we must be able to describe the structure of the world without mentioning any *names*. [Cf. 5.526.]

20.10.14.

Page 15

The proposition must enable us to see the logical structure of the situation that makes it true or false. (As a picture must shew the spatial relation in which the things represented in it must stand if the picture is correct (true).)

Page 15

The form of a picture might be called that in which the picture MUST agree with reality (in order to be capable of portraying it at all). [Cf. 2.17 and 2.18.]

Page 15

The first thing that the theory of logical portrayal by means of language gives us is a piece of information about the nature of the truth-relation.

Page 15

The theory of logical portrayal by means of language says--quite generally: In order for it to be possible that a proposition should be true or false--agree with reality or not--for this to be possible something in the proposition must be *identical* with reality. [Cf. 2.18.]

Page 15

What negates in "p" is not the "~" in front of the "p", but is what is common to all the signs that have the same meaning as "~p" in this notation; and therefore what is common in

$\sim p$
 $\sim \sim p$
 $\sim p \vee \sim p$
 $\sim p \cdot \sim p$
 etc. etc.

and the same holds for the generality notation, etc.

[Cf. 5.512.]

Page Break 16

Page 16

Pseudo-propositions are such as, when analysed, turn out after all only to *shew* what they were supposed to say.

Page 16

Here we have a justification for the feeling that the proposition describes a complex in the kind of way that Russellian descriptions do: the proposition describes the complex by means of its logical properties.

Page 16

The proposition constructs a world by means of its logical scaffolding, and that is why we can actually see in the proposition how everything logical would stand if it were true: we can *draw conclusions* from a false proposition, etc. (In this way I can see that if " $(x, \phi). \phi x$ " were true, this proposition would contradict a proposition " ψa ".) [Cf 4.023.]

Page 16

The possibility of inferring completely general propositions from material propositions--the fact that the former are capable of standing in *meaningful* [[sic]] internal relations with the latter--shews that the completely general propositions are logical constructions from situations.

21.10.14.

Page 16

Isn't the Russellian definition of nought nonsensical? Can we speak of a class $\hat{x} (x \neq x)$ at all?--Can we speak of a class $\hat{x} (x = x)$ either? For is $x \neq x$ or $x = x$ a function of x ?--Must not 0 be defined by means of the hypothesis $(\exists \phi):(x) \sim \phi x$? And something analogous would hold of all other numbers. Now this throws light on the whole question about the existence of numbers of things.

$$0 = \hat{\alpha} \{ (\exists \phi):(x) \sim \phi x. \alpha = \hat{u}(\phi u) \} \text{ Def.}$$

$$1 = \hat{\alpha} \{ (\exists \phi)::(\exists x). \phi x: \phi y. \phi z \hat{E}_{y,z} y = z: \alpha = \hat{u}(\phi u) \} \text{ Def.}$$

Page 16

[The sign of equality in the curly brackets could be *avoided* if we were to write:

$$0 = \hat{u}(\phi u) \{ (x) \sim \phi x \cdot \dagger 1 \}$$

Page 16

The proposition must *contain* (and in this way shew) the *possibility of its truth*. But not more than the *possibility*. [Cf. 2.203 and 3.02 and 3.13.]

Page 16

By my definition of classes $(x). \sim \hat{x}(\phi x)$ is the assertion that $x(\phi x)$ is null and the definition of 0 is in that case $0 = \hat{\alpha} [(x). \sim \alpha]$ Def.

Page Break 17

Page 17

I thought that the possibility of the truth of the proposition ϕa was tied up with the fact $(\exists x, \phi). \phi x$. But it is impossible to see why ϕa should only be possible if there is another proposition of the same form. ϕa surely does not need any precedent. (For suppose that there existed only the two elementary propositions " ϕa " and " ψa " and

that " ϕa ", were false: Why should this proposition only make sense if " ψa " is true?)

22.10.14.

Page 17

There must be something in the proposition that is identical with its reference, but the proposition cannot be identical with its reference, and so there must be something in it that is *not* identical with the reference. (The proposition is a formation with the logical features of what it represents and with other features besides, but these will be arbitrary and different in different sign-languages.) So there must be different formations with the same logical features; what is represented will be one of these, and it will be the business of the representation to distinguish this one from other formations with the same logical features. (Since otherwise the representation would not be unambiguous.) This part of the representation (the assignment of names) must take place by means of arbitrary stipulations. Every proposition must accordingly contain features with arbitrarily determined references.

Page 17

If one tries to apply this to a completely generalized proposition, it appears that there is some fundamental mistake in it.

Page 17

The generality of the completely general proposition is accidental generality. It deals with all the things that there chance to be. And that is why it is a material proposition.

23.10.14.

Page 17

On the one hand my theory of logical portrayal seems to be the only possible one, on the other hand there seems to be an insoluble contradiction in it!

Page 17

If the completely generalized proposition is not completely dematerialized, then a proposition does not get dematerialized at all through generalization, as I used to think.

Page 17

Whether I assert something of a particular thing or of all the things that there are, the assertion is equally material.

Page Break 18

Page 18

"All things"; that is, so to speak, a description taking the place of "a and b and c".

Page 18

Suppose our signs were just as indeterminate as the world they terror?

Page 18

In order to recognize the sign in the sign we have to attend to the use. [Cf. 3.326.]

Page 18

If we were to try and express what we express by means of " $(x).\phi x$ " by prefixing an index to " ϕx ", e.g., like this: "Gen. ϕx ", it would not be adequate (we should not know what was being generalized).

Page 18

If we tried to shew it by means of an index to the "x", e.g., like this: $\phi(x_G)$, it would still not be adequate (in this way we should not know the scope of generality).

Page 18

If we thought of trying to do it by inserting a mark in the empty argument places, e.g., like this: " $(G,G).\psi(G,G)$ " it would not be adequate (we could not settle the identity of the variables).

Page 18

All these methods of symbolizing are inadequate *because they do not have the necessary logical properties*. All those collections of signs lack the power to portray the requisite sense-in the proposed way. [Cf. 4.0411.]

24.10.14.

Page 18

In order to be able to frame a statement at all, we must--in some sense--know how things stand if the statement is true (and that is just what we portray). [Cf. 4.024.]

Page 18

The proposition *expresses* what I do not know; but what I must know in order to be able to say it at all, *I shew in it*.

Page 18

A definition is a tautology and shews internal relations between its two terms!

Page 18

But why do you never investigate an individual particular sign in order to find out how it is a logical portrayal?

Page 18

The completely analysed proposition must image its reference.

Page 18

We might also say that our difficulty starts from the completely generalized proposition's not appearing to be complex.

Page 18

It does not appear, like all other propositions, to consist of arbitrarily symbolizing component parts which are united in a logical form. It appears not to HAVE a form but itself to be a form complete in itself.

Page Break 19

Page 19

With the logical constants one need never ask whether they exist, for they can even *vanish!*

Page 19

Why should " $\phi(\hat{x})$ " not image how $(x).\phi x$ is the case? Doesn't it all depend here *only* on *how*--in what kind of way--that sign images something?

Page 19

Suppose that I wanted to represent four pairs of men fighting; could I not do so by representing only one and saying: "That is how they all four look"? (By means of this appendix I determine the kind of representation.) (Similarly I represent $(x).\phi x$ by means of " $\phi(\hat{x})$ ".)

Page 19

Remember that there are no hypothetical internal relations. If a structure is given and a structural relation to it, then there must be another structure with that relation to the first one. (This is involved in the nature of structural relations.)

Page 19

And this speaks for the correctness of the above remark: it stops it from being--an evasion.

26.10.14.

Page 19

So it looks as if the logical *identity* between sign and things signified were not necessary, but only *an* internal, *logical*, relation between the two. (The holding of such a relation incorporates in a certain sense the holding of a kind of fundamental--internal--identity.)

Page 19

The point is only that the logical part of what is signified should be completely determined just by the logical part of the sign and the method of symbolizing: sign and method of symbolizing *together* must be logically identical with what is signified.

Page 19

The sense of the proposition is what it images. [Cf. 2.221.]

27.10.14.

Page 19

" $x = y$ " is not a propositional form. (Consequences.)

Page 19

It is clear that " aRa " would have the same reference as " $aRb.a = b$ ". So we can make the pseudo-proposition " $a = b$ " disappear by means of a completely analysed notation. The best proof of the correctness of the above remark.

Page 19

The difficulty of my theory of logical portrayal was that of finding a connexion between the signs on paper and a situation outside in the world.

Page Break 20

Page 20

I always said that truth is a relation between the proposition and the situation, but could never pick out such a relation.

Page 20

The representation of the world by means of completely generalized propositions might be called the

impersonal representation of the world.

Page 20

How does the impersonal representation of the world take place?

Page 20

The proposition is a model of reality as we imagine it. (See 4.01.)

28.10.14.

Page 20

What the pseudo-proposition "There are n things" tries to express shews in language by the presence of n proper names with different references. (Etc.)

Page 20

What the completely general propositions describe are indeed in a certain sense structural properties of the world. Nevertheless these propositions can still be true or false. According as they *make sense* the world still has that permanent range.

Page 20

In the end the truth or falsehood of *every* proposition makes some difference to the general *structure* of the world. And the range which is left to its structure by the TOTALITY of all elementary propositions is just the one that is bounded by the completely general propositions. [Cf. 5.5262.]

29.10.14.

Page 20

For, if an elementary proposition is true, then at any rate *one more* elementary proposition is true, and conversely. [See 5.5262.]

Page 20

In order for a proposition to be true it must first and foremost be *capable* of truth, and that is all that concerns logic.

Page 20

The proposition must shew what it is trying to say.--Its relation to its reference must be like that of a description to its subject.

Page 20

The logical form of the situation, however, cannot be described.--[Cf. 4.12 and 4.121.]

Page 20

The internal relation between the proposition and its reference, the method of symbolizing is the system of co-ordinates which projects the situation into the proposition. The proposition corresponds to the fundamental co-ordinates.

Page 20

We might conceive two co-ordinates a_P and b_P as a proposition stating that the material point P is to be found in the place (ab) . For

Page Break 21

this statement to be possible the co-ordinates a and b must really determine a place. For a statement to be possible the logical coordinates must really determine a logical place!

Page 21

(The subject-matter of general propositions is really the world; which makes its appearance in them by means of a logical description.--And that is why the world does not really occur in them, just as the subject of the description does not occur in it.)

Page 21

The fact that in a certain sense the logical form of p must be present even if p is not the case, shews symbolically through the fact that " p " occurs in " $\sim p$ ".

Page 21

This is the difficulty: How can there be such a thing as the form of p if there is no situation of this form? And in that case, what does this form really consist in?

Page 21

There are no such things as analytic *propositions*.

30.10.14.

Page 21

Could we say: In " $\sim\phi(x)$ " " $\phi(x)$ " images how things are *not*?

Page 21

Even in a picture we could represent a negative fact by representing what is *not* the case.

Page 21

If, however, we admit these methods of representation, then what is really characteristic of the relation of *representing*?

Page 21

Can't we say: It's just that there are different logical co-ordinate-systems!

Page 21

There are different ways of giving a representation, even by means of a picture, and what represents is not merely the sign or picture but also the method of representation. *What is common to all representation is that they can be right or wrong, true or false.*

Page 21

Then--picture *and way of representing* are completely outside what is represented!

Page 21

The two together are true or false, namely *the picture, in a particular way*. (Of course this holds for the elementary proposition tool)

Page 21

Any proposition can be negated. And this shews that "true" and "false" mean the same for all propositions. (This is of the greatest possible importance.) (In contrast to Russell.)

Page Break 22

Page 22

The reference of the proposition must be fixed, as conning or contradicting it, through it *together with its method of representation*. [Cf. 4.023.]

Page 22

In logic there is no side by side, there cannot be any classification. [See 5.454.]

31.10.14.

Page 22

A proposition like " $(\exists x, \phi). \phi x$ " is just as complex as an elementary one. This comes out in our having to mention " ϕ " and " x " *explicitly* in the brackets. The two stand--independently--in symbolizing relations to the world, just as in the case of an elementary proposition " $\psi(a)$ ". [Cf. 5.5261.]

Page 22

Isn't it like this: The logical constants signalise the way in which the elementary forms of the proposition represent?

Page 22

The reference of the proposition must be fixed as confirming or contradicting it, by means of it and its way of representing. To this end it must be completely described by the proposition. [Cf. 4.023.]

Page 22

The way of representing does not portray; only the proposition is a picture.

Page 22

The way of representing determines how the reality has to be compared with the picture.

Page 22

First and foremost the elementary propositional form must portray; all portrayal takes place through it.

1.11.14.

Page 22

We readily confuse the representing relation which the proposition has to its reference, and the truth relation. The former is different for different propositions, the latter is one and the same for all propositions.

Page 22

It looks as if " $(x, \phi). \phi x$ " were the form of a fact $\phi a. \psi b. \theta c$ etc. (Similarly $(\exists x). \phi x$ would be the form of ϕa , as I actually thought.)

Page 22

And this must be where my mistake is.

Page 22

Examine the elementary proposition: What is the form of " ϕa " and how is it related to " $\sim \phi(a)$ "?

Page 22

That precedent to which we should always like to appeal must be involved in the sign itself. [Cf. 5.525.]

Page Break 23

Page 23

The logical form of the proposition must already be given by the forms of its component parts. (And these have to do only with the *sense* of the propositions, not with their truth and falsehood.)

Page 23

In the form of the subject and of the predicate there already lies the possibility of the subject-predicate proposition, etc.; but fair enough--nothing about its truth or falsehood.

Page 23

The picture has whatever relation to reality it does have. And the point is how it is supposed to represent. The same picture will agree or fail to agree with reality according to how it is supposed to represent.

Page 23

Analogy between proposition and description: *The complex which is congruent with this sign.* (Exactly as in representation in a map.)

Page 23

Only it just cannot be *said* that this complex is congruent with that (or anything of the kind), but this shews. And for this reason the description assumes a different character. [Cf. 4.023.]

Page 23

The method of portrayal must be completely determinate before we can compare reality with the proposition at all in order to see whether it is true or false. The method of comparison must be given me before I can make the comparison.

Page 23

Whether a proposition is true or false is something that has to appear.

Page 23

We must however know in advance *how* it will appear.

Page 23

That two people are not fighting can be represented by representing: them as not fighting and also by representing them as fighting and saying that the picture shews how things are *not*. We *could* represent by means of negative facts just as much as by means of positive ones----. However, all we want is to investigate the principles of representing *as such*.

Page 23

The proposition "'p' is true" has the same reference as the logical product of 'p', and a proposition "'p'" which describes the proposition 'p', and a correlation of the components of the two propositions.--The internal relations between proposition and reference are portrayed by means of the internal relations between 'p' and "'p'". (Bad remark.)

Page 23

Don't get involved in partial problems, but always take flight to where there is a free view over the whole *single* great problem, even if this view is still not a clear one.

Page Break 24

Page 24

'A situation is thinkable' ('imaginable') means: We can make ourselves a picture of it. [3.001.]

Page 24

The proposition must determine a logical place.

Page 24

The existence of this logical place is guaranteed by the existence of the component parts alone, by the existence of the significant proposition.

Page 24

Supposing there is no complex in the logical place, there is one then that is: not in that logical place. [Cf. 3.4.]
2.11.14.

Page 24

In the tautology the conditions of agreement with the world (the truth-conditions)--the representing relations--cancel one another out, so that it does not stand in any representing relation to reality (says nothing). [Cf. 4.462.]

Page 24

$a = a$ is not a tautology in the same sense as $p \supset p$.

Page 24

For a proposition to be true does not consist in its having a *particular* relation to reality but in its really *having* a particular relation.

Page 24

Isn't it like this: the false proposition makes sense like the true and independently of its falsehood or truth, but it has no reference? (Is there not here a better use of the word "reference"?)

Page 24

Could we say: As soon as I am given subject and predicate I am given a relation which will *exist* or not *exist* between a subject-predicate proposition and its reference. As soon as I really know subject and predicate, I can also know about the relation, which is an indispensable presupposition even for the case of the subject-predicate proposition's being false.

3.11.14.

Page 24

In order for it to be possible for a negative situation to exist, the picture of the positive situation must exist. [Cf. 5.5151.]

Page 24

The knowledge of the representing relation *must* be founded only on the knowledge of the component parts of the situation!

Page 24

Then would it be possible to say: the knowledge of the subject predicate proposition and of subject and predicate gives us the knowledge of an internal relation, etc.?

Page 24

Even this is not strictly correct since we do not need to know any particular subject or predicate.

Page Break 25

Page 25

It is *evident* that we feel the elementary proposition as the picture of a situation.--How is this? [Cf. 4.012.]

Page 25

Must not the possibility of the representing relation be given by the proposition *itself*?

Page 25

The proposition *itself* sunders what is congruent with it from what is not congruent.

Page 25

For example: if the proposition is given, and congruence, then the proposition is true if the situation is congruent with it. Or: the proposition is given and non-congruence; then the proposition is true if the situation is not congruent with it.

Page 25

But how is congruence or non-congruence or the like given us?

Page 25

How can I be *told how* the proposition represents? Or can this not be *said* to me at all? And if that is so can I "*know*" it? If it was supposed to be said to me, then this would have to be done by means of a proposition; but the proposition could only shew it.

Page 25

What can be said can only be said by means of a proposition, and so nothing that is necessary for the understanding of *all* propositions can be said.

Page 25

That arbitrary correlation of sign and thing signified which is a condition of the possibility of the propositions, and which I found lacking in the completely general propositions, occurs there by means of the generality notation, just as in the elementary proposition it occurs by means of names. (For the generality notation does not belong to the *picture*.) Hence the constant feeling that generality makes its appearance quite like an argument. [Cf. 5.523.]

Page 25

Only a finished proposition can be negated. (And similarly for all ab-functions.)†1 [Cf. 4.064 and 4.0641.]

Page 25

The proposition is the logical picture of a situation.

Page 25

Negation refers to the *finished* sense of the negated proposition and not to its way of presenting. [Cf. 4.064 and 4.0641.]

Page 25

If a picture presents what-is-not-the-case in the forementioned way, this only happens through its presenting *that* which *is* not the case.

Page 25

For the picture says, as it were: "*This* is how it is *not*", and to the question "*How* is it not?" just the positive proposition is the answer.

Page Break 26

Page 26

It might be said: The negation refers to the very logical place which is determined by the negated proposition. [See 4.0641.]

Page 26

Only don't lose the solid ground on which you have just been standing!

Page 26

The negating proposition determines a *different* logical place from the negated proposition. [See 4.0641.]

Page 26

The negated proposition not only draws the boundary between the negated domain and the rest; it actually points to the negated domain.

Page 26

The negating proposition uses the logical place of the negated proposition to determine its own logical place. By describing the latter as the place that is outside the former. [See 4.0641.]

Page 26

The proposition is true when what it images exists.

4.11.14.

Page 26

How does the proposition determine the logical place?

Page 26

How does the picture present a situation?

Page 26

It is after all itself not the situation, which need not be the case at all.

Page 26

One name is representative of one thing, another of another thing, and they themselves are connected; in this way--like a *tableau vivant*--the whole images the situation. [Cf. 4.0311.]

Page 26

The logical connexion must, of course, be one that is possible as between the things that the names are representatives of, and this will always be the case if the names really are representatives of the things. N.B. that connexion is not a relation but only the *holding* of a relation.

5.11.14.

Page 26

In this way the proposition represents the situation--as it were off its own bat.

Page 26

But when I say: the connexion of the propositional components must be possible for the represented things--does this not contain the whole problem? How can a non-existent connexion between objects be possible?

Page 26

"The connexion must be possible" means: The proposition and the components of the situation must stand in a particular relation.

Page Break 27

Page 27

Then in order for a proposition to present a situation it is only necessary for its component parts to represent those of the situation and for the former to stand in a connexion which is possible for the latter.

Page 27

The propositional sign guarantees the possibility of the fact which it presents (not, that this fact is actually the case)--this holds for the general propositions too.

Page 27

For if the positive fact ϕa is given then so is the *possibility* of $(x).\phi x$, $\sim(\exists x).\phi x$, $\sim\phi a$ etc. etc. (All logical constants are already contained in the elementary proposition.) [Cf. 5.47.]

Page 27

That is how the picture arises.--

Page 27

In order to designate a logical place with the picture we must attach a way of symbolizing to it (the positive, the negative, etc.).

Page 27

We might, e.g., shew how *not* to fence by means of fencing puppets.

6.11.14.

Page 27

And it is just the same with this case as with $\sim\phi a$, although the picture deals with what *should* not happen instead of with what does not happen.

Page 27

The possibility of negating the negated proposition in its turn shews that what is negated is already a proposition and not merely the preliminary to a proposition. [See 4.0641.]

Page 27

Could we say; Here is the picture, but we cannot tell whether it is right or not until we know what it is supposed to say.

Page 27

The picture must now in its turn cast its shadow on the world.

7.11.14.

Page 27

Spatial and logical place agree in both being the possibility of an existence. [Cf. 3.411.]

8.11.14.

Page 27

What can be confirmed by experiment, in propositions about probability, cannot possibly be mathematics. [Cf. 5.154.]

Page 27

Probability propositions are abstracts of scientific laws. [Cf. 5.156.]

Page 27

They are generalizations and express an incomplete knowledge of those laws. [Cf. 5.156.]

Page Break 28

Page 28

If, e.g., I take black and white balls out of an urn I cannot say before taking one out whether I shall get a white or a black ball, since I am not well enough acquainted with the natural laws for that, but *all the same I do know* that if there are equally many black and white balls there, the numbers of black balls that are drawn will approach the number of white ones if the drawing is continued; I do know the natural laws as accurately as *this*. [Cf. 5.154]

9.11.14.

Page 28

Now what I know in probability statements are certain general properties of ungeneralized propositions of natural science, such as, e.g., their symmetry in certain respects, and asymmetry in others, etc. [Cf. 5.156.]

Page 28

Puzzle pictures and the seeing of situations. [Cf. 5.5423.]

Page 28

It has been what I should like to call my strong scholastic feeling that has occasioned my best discoveries.

Page 28

"Not p" and "p" contradict one another, both cannot be true; but I can surely express both, *both pictures exist*. They are to be found side by side.

Page 28

Or rather "p" and " $\sim p$ " are like a picture and the infinite plane outside this picture. (Logical place.)

Page 28

I can construct the infinite space outside only by using the picture to bound that space.

10.11.14.

Page 28

When I say "p is possible", does that mean that "p" makes sense? Is the former proposition about language, so that the existence of a propositional sign ("p") is essential for its sense? (In that case it would be quite unimportant.) But does it not rather try to say what " $p \vee \sim p$ " shews?

Page 28

Does not my study of sign language correspond to the study of the processes of thought, which philosophers

have always taken as so essential for philosophy of logic?--Only they always got involved in inessential psychological investigations, and there is an analogous danger with my method too. [See 4.1121.]

11.11.14.

Page 28

Since "a = b" is not a proposition, nor "x = y" a function, a "class $\hat{x} (x = x)$ " is a chimera, and so equally is the so-called null class. (One

Page Break 29

did indeed always have the feeling that wherever $x = x$, $a = a$, etc. were used in the construction of sentences, in all such cases one was only getting out of a difficulty by means of a swindle; as though one said "a exists" means " $(\exists x)x = a$ ".)

Page 29

This is wrong: since the definition of classes itself guarantees the existence of the real functions.

Page 29

When I appear to assert a function of the null class, I am saying that this function is true of all functions that are null--and I can say that even if *no* function is null.

Page 29

Is $x \neq x$. $\equiv_x \phi x$ identical with
 $(x) \sim \phi x$? Certainly!

Page 29

The proposition points to the possibility that such and such is the case.

12.11.14.

Page 29

The negation is *a description* in the same sense as the elementary proposition itself.

Page 29

The truth of the proposition might be called possible, that of a tautology certain, and that of a contradiction impossible. Here we already get the hint of a gradation that we need in the probability calculus. [Cf. 4.464.]

Page 29

In the tautology the elementary proposition does, of course, still portray, but it is so loosely connected with reality that reality has unlimited freedom. Contradiction in its turn imposes such constraints that no reality can exist under them.

Page 29

It is as if the logical constants projected the picture of the elementary proposition on to reality--which may then accord or not accord with this projection.

Page 29

Although all logical constants must already occur in the simple proposition, its own peculiar proto-picture *must* surely also occur in it whole and undivided.

Page 29

Then is the picture perhaps not the simple proposition, but rather its prototype which must occur in it?

Page 29

Then, this prototype is not actually a proposition (though it has the Gestalt of a proposition) and it might correspond to Frege's "assumption".

Page Break 30

Page 30

In that case the proposition would consist of proto-pictures, which were projected on to the world.

13.11.14.

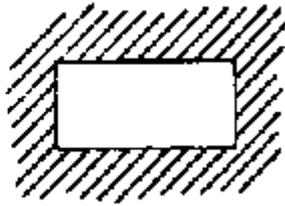

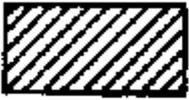

Page 30

In this work more than any other it is rewarding to keep on looking at questions, which one considers solved, from another quarter, as if they were unsolved.

14.11.14.

Page 30

Think of the representation of *negative* facts by means of models. E.g.: two railway trains must not stand on the rails in such-and-such a way. The proposition, the picture, the model are--in the negative sense--like a solid body restricting the freedom of movement of others; in the positive sense, like the space bounded by solid substance, in which there is room for a body. [Cf. 4.463.]

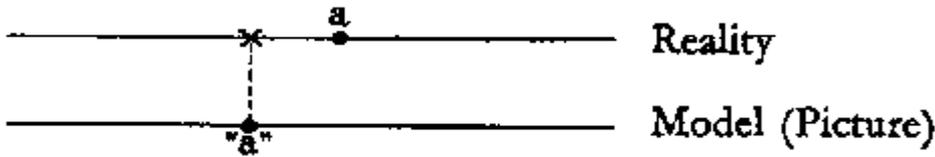

This image is *very* clear and must lead to the solution.

15.11.14.

Page 30

Projection of the picture on to reality.

(Maxwell's method of mechanical models.)

Page 30

Don't worry about what you have already written. Just keep on beginning to think afresh as if nothing at all had happened yet.

Page 30

That shadow which the picture as it were casts upon the world: How am I to get an exact grasp of it?

Page 30

Here is a deep mystery.

Page 30

It is the mystery of negation: This is not how things are, and yet we can say *how* things are *not*.--

Page 30

For the proposition is only the *description* of a situation. (But this is all still only on the surface.) [Cf. 4.023.]

Page Break 31

Page 31

A single insight at the start is worth more than ever so many somewhere in the middle.

16.11.14

Page 31

The introduction of the sign "0" in order to make the decimal notation possible: the logical significance of this procedure.

17.11.14.

Page 31

Suppose " ϕa " is true: what does it mean to say $\sim\phi a$ is possible? (ϕa is itself equivalent in meaning with $\sim(\sim\phi a)$.)

18.11.14.

Page 31

It is all simply a matter of the existence of the logical place. But what the devil is this "logical place"?!

19.11.14.

Page 31

The proposition and the logical co-ordinates: that is the logical place. [Cf. 3.41.]

20.11.14.

Page 31

The reality that corresponds to the sense of the proposition can surely be nothing but its component parts, since we are surely *ignorant of everything* else.

Page 31

If the reality consists in anything else as well, this can at any rate neither be denoted nor expressed; for in the first case it would be a further component, in the second the expression would be a proposition, for which the same problem would exist in turn as for the original one.

Page 31

What do I really know when I understand the sense of " ϕa " but do not know whether it is true or false? In that case I surely know no more than $\phi a \vee \sim\phi a$; and that means I *know* nothing.

Page 31

As the realities corresponding to the sense of a proposition are only its component parts, the logical co-ordinates too can only refer to these.

22.11.14.

Page 31

At this point I am again trying to express something that cannot be expressed.

23.11.14.

Page 31

Although the proposition must only point to a region of logical space, still the whole of logical space must *already* be given by means of it.--

Page Break 32

Otherwise *new* elements--and in co-ordination--would keep on being introduced by means of negation, disjunction, etc.; which, of course, must not happen. [Cf. 3.42.]

24.11.14.

Page 32

Proposition and situation are related to one another like the yardstick and the length to be measured.

Page 32

That the *proposition* " ϕa " can be inferred from the *proposition* " $(x).\phi x$ " shews how generality is present even in the *sign* " $(x).\phi x$ ".

Page 32

And the same thing, of course, holds for any generality notation.

Page 32

In the proposition we hold a proto-picture up against reality.

Page 32

(When investigating negative facts one keeps on feeling as if they presupposed the existence of the propositional sign.)

Page 32

Must the sign of the negative proposition be constructed by means of the sign of the positive one? (I believe so.)

Page 32

Why shouldn't one be able to express the negative proposition by means of a negative fact? It's as if one were to take the space outside the yardstick as the object of comparison instead of the yardstick. [Cf. 5.5151.]

Page 32

How does the *proposition* " $\sim p$ " really contradict the *proposition* " p "? The internal relations of the two signs must mean contradiction.

Page 32

Of course it must be possible to ask whenever we have a negative proposition: *What* is it that is *not* the case? But the answer to this is, of course, in its turn only a proposition. (This remark incomplete.)

25.11.14.

Page 32

That negative state of affairs that serves as a sign can, of course, perfectly well exist without a proposition that in turn expresses it.

Page 32

In investigating these problems it's constantly as if they were already solved, an illusion which arises from the fact that the problems often quite disappear from our view.

Page 32

I can see that $\sim\phi a$ is the case just by observing $\phi z x q$  and a.

Page 32

The question here is: Is the positive fact primary, the negative secondary, or are they on the same level? And if so, how is it with the facts $p \vee q$, $p \supset q$, etc.? Aren't these on the same level as $\sim p$? But then

Page Break 33

must not *all facts* be on the same level? The question is really this: fire there facts besides the positive ones? (For it is difficult not to confuse what is not the case with what *is* the case instead of it.)

Page 33

It is clear that all the ab-functions are only so many different methods for measuring reality.--And certainly the methods of measurement by means of p and $\sim p$ have some special advantage over all others.--

Page 33

It is the *dualism*, positive and negative facts, that gives me no peace. For such a dualism can't exist. But how to get away from it?

Page 33

All this would get solved of itself if we understood the nature of the proposition.

26.11.14.

Page 33

If all the positive statements about a thing are made, aren't all the negative ones already made too? And that is the whole point.

Page 33

The dualism of positive and negative that I feared does not exist, for $(x).\phi x$, etc. etc. are neither positive nor negative.

Page 33

If the positive proposition does not *have* to occur in the negative, mustn't at any rate the proto-picture of the positive proposition occur in the negative one?

Page 33

By making a distinction--as we do in any possible notation--between $\sim aRb$ and $\sim bRa$ we presuppose in any notation a particular correlation between argument and argument place in the negative proposition; the correlation gives the prototype of the negated positive proposition.

Page 33

Then is that correlation of the components of the proposition by means of which nothing is yet *said* the real picture in the proposition?

Page 33

Doesn't my lack of clarity rest on a lack of understanding of the nature of relations?

Page 33

Can one negate a *picture*? No. And in this lies the difference between picture and proposition. The picture can serve as a proposition. But in that case something gets added to it which brings it about that now it *says* something. In short: I can only deny that the picture is right, but the *picture* I cannot deny.

Page 33

By my correlating the components of the picture with objects, it

Page Break 34

comes to represent a situation and to be right or wrong. (E.g., a picture represents the inside of a room, etc.)

27.11.14.

" $\sim p$ " is true when p is false. So part of the true proposition " $\sim p$ " is a false proposition. How can the mere twiddle " \sim " bring it into agreement with reality? We have, of course, already said that it is not the twiddle " \sim " alone but everything that is common to the different signs of negation. And what is common to all these must obviously proceed from the meaning of negation itself. And so in this way the sign of negation must surely mirror its own reference. [Cf. 5.512.]

28.11.14.

Page 34

Negation combines with the ab-functions of the elementary proposition. And the logical functions of the elementary proposition must mirror their reference, just as much as all the others.

29.11.14.

Page 34

The ab-function does not stop short of the elementary proposition but penetrates it.

Page 34

What *can* be shewn cannot be said. [4.1212.]

Page 34

I believe that it would be possible wholly to exclude the sign of identity from our notation and always to indicate identity merely by the identity of the signs (and conversely). In that case, of course, $\phi(a,a)$ would not be a special case of $(x,y).\phi(x,y)$, and ϕa would not be a special case of $(\exists x,y).\phi x.\phi y$. But then instead of $\phi x.\phi y \supset_{x,y} x = y$ one could simply write $\sim(\exists x,y).\phi x.\phi y$. [Cf. 5.53 and 5.533]

Page 34

By means of this notation the pseudo-proposition $(x)x = a$ or the like would lose all appearances of justification. [Cf. 5.534.]

1.12.14.

Page 34

The proposition says as it were: This picture cannot (or can) present a situation in this way.

2.12.14.

Page 34

It all depends on settling what distinguishes the proposition from the mere picture.

4.12.14.

Page 34

Let us look at the identity $\sim\sim p = p$: this, together with others, determines the sign for p , since it says that there is something that "p"

Page Break 35

and " $\sim\sim p$ " have in common. Through this that sign acquires properties which mirror the fact that double negation is an affirmation.

5.12.14.

Page 35

How does " $p \vee \sim p$ " say nothing?

6.12.14.

Page 35

Newtonian mechanics brings the description of the world into a unitary form. Let us imagine a white surface with irregular black spots on it. We now say: Whatever sort of picture arises in this way, I shall always be able to approximate as close as I like to its description by covering the surface with a suitably fine square network and saying of each square that it is white or is black. In this way I shall have brought the description of this surface into a unitary form. This form is arbitrary, for I could with equal success have used a triangular or hexagonal net. It may be that the description by means of a triangular net would have been simpler, i.e. that we could have given a more accurate description of the surface with a coarser triangular net than with a finer square one (or vice versa), etc. Different systems of describing the world correspond to the different nets. Mechanics determines the form of description of the world by saying: All propositions in a description of the world must be capable of being got in a given way from a number of given propositions--the axioms of mechanics. In this way it supplies the stones for building up natural science and says: Whatever building you want to erect you must construct it somehow with these and only these stones.

Page 35

Just as it must be possible to write down any arbitrary number by means of the system of numbers, so it must be possible to write down any arbitrary proposition of physics by means of the system of mechanics.

Page 35

[6.341.]

Page 35

And here we see the relative position of logic and mechanics.

Page 35

(One might also allow the net to consist of a variety of figures.)

Page 35

The fact that a configuration like that mentioned above can be described by means of a net of a given form asserts nothing about the configuration (for this holds for any such configuration). What does characterize the configuration however is that it can be described by means of a particular net of a *particular* degree of fineness. In this way too it tells us nothing about the world that it can be described by means of Newtonian mechanics; but it does tell us something that it can be

Page Break 36

described by means of Newtonian mechanics in the way that it actually can. (This I have felt for a *long* time.)--It also

asserts something about the world, that it can be described more simply by means of one mechanics than by means of another.

Page 36

[Cf. 6.342.]

Page 36

Mechanics is *one* attempt to construct all the propositions that we need for the description of the world according to a *single* plan. (Hertz's invisible masses.) [Cf. 6.343.]

Page 36

Hertz's invisible masses are admittedly pseudo-objects.

7.12.14.

Page 36

The logical constants of the proposition are the conditions of its truth.

8.12.14.

Page 36

Behind our thoughts, true and false, there is always to be found a dark background, which we are only later able to bring into the light and express as a thought.

12.12.14.

Page 36

p. Taut = p, i.e. Taut says nothing. [Cf. 4.465.]

13.12.14.

Page 36

Does it exhaust the nature of negation that it is an operation cancelling itself? In that case χ would have to stand for negation if $\chi\chi p = p$, assuming that $\chi p \neq p$.

Page 36

This for one thing is certain, that according to these two equations χ can no longer express affirmation.

Page 36

And does not the capacity which these operations have of vanishing shew that they are logical?

15.12.14.

Page 36

It is obvious that we can introduce whatever we like as the written signs of the ab-function, the real sign will form itself automatically. And when this happens what properties will be formed of themselves?

Page 36

The logical scaffolding surrounding the picture (in the proposition) determines logical space. [Cf. 3.42.]

16.12.14.

Page 36

The proposition must reach out through the whole of logical space. [Cf. 3.42.]

Page Break 37

17.12.14.

Page 37

The signs of the ab-function are not material, otherwise they could not vanish. [Cf. 5.44 and 5.441.]

18.12.14.

Page 37

It must be possible to distinguish just as much in the real propositional sign as can be distinguished in the situation. This is what their identity consists in. [Cf. 4.04.]

20.12.14.

Page 37

In "p" neither more nor less can be recognized than in " $\sim p$ ".

Page 37

How can a situation agree with "p" and not agree with " $\sim p$ "?

Page 37

The following question might also be asked: If I were to try to invent *Language* for the purpose of making myself understood to someone else, what sort of rules should I have to agree on with him about our expression?

23.12.14.

Page 37

A characteristic example for my theory of the significance of descriptions in physics: The two theories of

heat; heat conceived at one time as a stuff, at another time as a movement.

25.12.14.

Page 37

The proposition says something, is identical with: It has a particular relation to reality, *whatever this may be*. And if this *reality* is given and also that relation, then the sense of the proposition is known. " $p \vee q$ " has a different relation to reality from " $p \cdot q$ ", etc.

Page 37

The possibility of the proposition is, of course, founded on the principle of signs as GOING PROXY for objects. [Cf. 4.0312.]

Page 37

Thus in the proposition something has *something else* as its proxy.

Page 37

But there is also the *common cement*.

Page 37

My fundamental thought is that the logical constants are not proxies. That the *logic* of the fact cannot have anything as its proxy. [See 4.0312.]

29.12.14.

Page 37

In the proposition the name goes proxy for the object. [3.22.]

11.1.15.

Page 37

A yardstick does not say that an object that is to be measured is one yard long.

Page Break 38

Page 38

Not even when we know that it is supposed to serve for the measurement of this *particular* object.

Page 38

Could we not ask: What has to be added to that yardstick in order for it to *assert* something about the length of the object?

Page 38

(The yardstick without this addition would be the "assumption".)

15.1.15.

Page 38

The propositional sign " $p \vee q$ " is right if p is the case, if q is the case and if both are the case, otherwise it is wrong. This seems to be infinitely simple; and the solution will be *as* simple as this.

16.1.15.

Page 38

The proposition is correlated with a hypothetical situation.

Page 38

This situation is given by means of its description.

Page 38

The proposition is the description of a situation. [See 4.023.]

Page 38

As the description of an object describes it by its external properties, so the proposition describes the fact by its internal properties. [See 4.023.]

Page 38

The description is right if the object has the asserted property: the proposition is right if the situation has the internal properties given by the proposition.

17.1.15.

Page 38

The situation $p \cdot q$ *falls under* the proposition " $p \vee q$ ".

Page 38

On the analogy of the net for physics: although the spots are geometrical figures, all the same geometry can, of course, say nothing at all about their form and position. The net, however, is *purely* geometrical, all its properties can be given *a priori*. [See 6.35.]

18.1.15.

Page 38

The comparison between proposition and description is purely logical and for that reason *must* be carried farther.

20.1.15.

Page 38

How is it that *all* is a logical concept?

Page 38

How is it that *all* is a concept of form?

Page 38

How does it come about that *all* can occur in any proposition?

Page Break 39

Page 39

For that is the characteristic mark of the concept of a form.

Page 39

All APPEARS to be nearer to the content of the proposition than to the form.

Page 39

All: things, All: functions, All: relations: it is as if All were a connecting *term* between the concept of the thing, of functions, etc., and the individual thing, the individual functions.

Page 39

Generality is essentially connected with the elementary FORM.

Page 39

The key word--?

21.1.15.

Page 39

The transition from the general consideration of the propositional form: *infinitely difficult, fantastic*.

22.1.15.

Page 39

My *whole* task consists in explaining the nature of the proposition.

Page 39

That is to say, in giving the nature of all facts, whose picture the proposition *is*.

Page 39

In giving the nature of all being.

Page 39

(And here Being does not mean existing--in that case it would be nonsensical.)

23.1.15.

Page 39

Negation is an operation. [*Cf.* 5.2341.]

Page 39

An operation denotes an operation.

Page 39

Words are probes; some reach very deep; some only to a little depth.

Page 39

An operation, of course, does not say anything, only its result does; and this depends on its object. [*Cf.* 5.25.]

24.1.15.

Page 39

The logical pseudo-functions *are* operations.

Page 39

Only operations can vanish!

Page 39

The negative proposition excludes reality.

Page 39

How can the all-embracing world-mirroring logic make use of such special twiddles and manipulations? Only by all these being linked together to form one *infinitely* fine network, to form the great mirror. [5.511.]

Page Break 40

	25.1.15.
Page 40	
We can also say: $\sim p$ is false, when p is true.	29.1.15.
Page 40	
Language is articulated. [Cf. 3.141.]	7.2.15.
Page 40	
Musical themes are in a certain sense propositions. Knowledge of the nature of logic will for this reason lead to knowledge of the nature of music.	14.2.15.
Page 40	
If there were mathematical objects--logical constants--the proposition "I am eating five plums" would be a proposition of mathematics. And it is not even a proposition of applied mathematics.	
Page 40	
The proposition must describe its reference <i>completely</i> . [Cf. 4.023.]	4.3.15.
Page 40	
A tune is a kind of tautology, it is complete in itself; it satisfies itself.	5.3.15.
Page 40	
Mankind has always had an inkling that there must be a sphere of questions where the answers must-- <i>a priori</i> --be arranged symmetrically, and united into a complete regular structure. [See 5.4541.]	
Page 40	
(The older a word, the deeper it reaches.)	6.3.15.
Page 40	
The problems of negation, of disjunction, of true and false, are only reflections of the one great problem in the variously placed great and small mirrors of philosophy.	7.3.15.
Page 40	
Just as $\sim\xi$, $\sim\xi \vee \sim\xi$ etc. are the same function, so too are $\sim\eta \vee \eta$, $\eta \supset \eta$, etc. the same--that is, the tautological--function. Just as the others can be investigated, so can it--and perhaps with advantage.	8.3.15.
Page 40	
My difficulty is only an--enormous--difficulty of expression.	18.3.15.
Page 40	
It is clear that the closest examination of the propositional sign cannot yield what it asserts--what it can yield is what it is <i>capable</i> of asserting.	
Page Break 41	
	27.3.15.
Page 41	
The picture can replace a description.	29.3.15.
Page 41	
The law of causality is not a law but the form of a law. [Cf. 6.32.]	
Page 41	
"Law of causality" is a class name. And just as in mechanics--let us say--there are minimum laws--e.g., that of least action--so in physics there is A law of causality, a law of the causality form. [Cf. 6.321.]	
Page 41	
Just as men also had an inkling of the fact that there must be a "law of least action", before precisely knowing how it ran.	
Page 41	
(Here, as so often happens, the <i>a priori</i> turns out to be something purely logical.)	

Page 41	[Cf. 6.3211.]	3.4.15.
Page 41	The proposition is a measure of the world.	
Page 41	This is the picture of a process and is wrong. In that case how can it still be a picture of that process?	
Page 41	"a" <i>can</i> go proxy for a and "b" <i>can</i> go proxy for b when "a" stands in the relation "R" to "b": this is what that POTENTIAL internal relation that we are looking for consists in.	5.4.15.
Page 41	The proposition is not a blend of words. [See 3.141.]	11.4.15.
Page 41	Nor is a tune a blend of notes, as all unmusical people think. [Cf. 3.141.]	12.4.15.
Page 41	I <i>cannot</i> get from the nature of the proposition to the individual logical operations!!!	15.4.15.
Page 41	That is, I cannot bring out how far the proposition is the <i>picture</i> of the situation.	
Page 41	I am almost inclined to give up all my efforts.---- ----	16.4.15.
Page 41	Description is also, so to speak, an operation with the means of description as its basis, and with the described object as its result.	
Page Break 42		
Page 42	The sign "not" is the class of all negating signs.	17.4.15.
Page 42	The subjective universe.	
Page 42	Instead of performing the logical operations in the proposition upon its component propositions, we can correlate <i>marks</i> with these and operate with them. In that case a single propositional formation has correlated with it a constellation of marks which is connected with it in a most complicated way.	
Page 42	$(aRb, cSd, \phi e) ((p \vee q).r: \supset q.r. \equiv p \vee r)$	
Page 42	p q r	18.4.15.
Page 42	The transition from p to $\sim p$ is <i>not</i> what is characteristic of the operation of negation. (The <i>best proof</i> of this: negation also leads from $\sim p$ to p.)-----.	19.4.15.
Page 42	What is mirrored in language I cannot use language to express. [Cf. 4.121.]	23.4.15.
Page 42	We do not believe <i>a priori</i> in a law of conservation, we <i>know a priori</i> the possibility of its logical form. [6.33.]	
Page 42	All those propositions which are known <i>a priori</i> , like the principle of sufficient reason, of continuity in	

nature, etc., etc., all these are *a priori* insights relating to the possible ways of forming the propositions of natural science. [Cf. 6.34.]

Page 42

"Ockham's razor" is, *of course*, not an arbitrary rule or one justified by its practical success. What it says is that unnecessary sign-units mean nothing. [See 5.47321.]

Page 42

It is clear that signs fulfilling the same purpose are logically identical. The purely logical thing just *is* what *all* of these are capable of accomplishing [Cf. 5.47321.]

24.4.15.

Page 42

In logic (mathematics) process and result are equivalent. (Hence no surprises.) [6.1261.]

25.4.15.

Page 42

Since language stands in *internal* relations to the world, *it* and these relations determine the logical possibility of facts. If we have a significant

Page Break 43

sign it must stand in a particular internal relation to a structure. Sign and relation determine unambiguously the logical form of the thing signified.

Page 43

But cannot any so-called thing be correlated in one and the same way with any other such?

Page 43

It is, for example, quite clear that the separate words of language are--experienced and--used as logically equivalent units.

Page 43

It always seems as if there were something that one *can regard as a thing*, and *on the other hand* real simple things.

Page 43

It is clear that neither a pencil-stroke nor a steamship is simple. Is there really a logical equivalence between these two?

Page 43

"Laws" like the law of sufficient reason, etc. deal with the network not with what the network describes. [See 6.35.]

26.4.15.

Page 43

It must be through generality that ordinary propositions get their stamp of simplicity.

Page 43

We must recognize *how* language takes care of itself.

Page 43

The proposition that is about a complex stands in internal relation to the proposition about its component part. [See 3.24.]

27.4.15.

Page 43

The freedom of the will consists in the fact that future events *cannot* be KNOWN now. It would only be possible for us to know them, if causality were an INNER necessity--like, say, that of logical inference.--The connexion between knowledge and thing known is *the* connexion of logical necessity. [See 5.1362.]

Page 43

I cannot need to worry about language.

Page 43

Non-truth is like non-identity.

28.4.15.

Page 43

The operation of negating does not consist in, say, putting down a \sim , but in the class of all negating operations.

Page 43

But in that case what really are the properties of this ideal negating operation?

Page 43

How does it come out that two assertions are compatible?

Page 43

If one puts p instead of q in $p \vee q$ the statement turns into p .

Page Break 44

Page 44

Does the sign $p.q$ also belong among those which assert p ?--Is p one of the signs for $p \vee q$?

Page 44

Can one say the following?: All signs that do *not* assert p , are *not* asserted by p and do *not* contain p as tautology or contradiction does--all these signs negate p .

29.4.15.

Page 44

That is to say: All signs that are dependent on p and that neither assert p nor are asserted by p .

30.4.15.

Page 44

The occurrence of an *operation* cannot, *of course*, have any import by itself.

Page 44

p is asserted by all propositions from which it follows. [5.124.]

Page 44

Every proposition that contradicts p negates p . [See 5.1241.]

1.5.15.

Page 44

The fact that $p.\sim p$ is a contradiction shews that $\sim p$ contradicts p . [Cf. 6.1201.]

Page 44

Scepticism is *not* irrefutable, but *obvious nonsense* if it tries to doubt where no question can be asked. [See 6.51.]

Page 44

For doubt can only exist where a question exists; a question can only exist where an answer exists, and this can only exist where something *can* be said. [See 6.51.]

Page 44

All theories that say: "This is how it must be, otherwise we could not philosophize" or "otherwise we surely could not live", etc. etc., must of course disappear.

Page 44

My method is not to sunder the hard from the soft, but to see the hardness of the soft.

Page 44

It is one of the chief skills of the philosopher not to occupy himself with questions which do not concern him.

Page 44

Russell's method in his "Scientific method in philosophy" is simply a retrogression from the method of physics.

2.5.15.

Page 44

The class of all signs that assert both p and q is the sign for $p.q$. The class of all signs which assert either p or q is the proposition " $p \vee q$ ". [Cf. 5.513.]

Page Break 45

3.5.15.

Page 45

We cannot say that both tautology and contradiction say *nothing* in the sense that they are both, say, zero points in a scale of propositions. For at least they are *opposite* poles.

Page 45

Can we say: two propositions are opposed to one another when there is no sign that asserts them both--which really means: when they have no common member? [Cf. 5.1241.]

Page 45

Thus propositions are imagined as classes of signs--the propositions " p " and " q " have the member " $p.q$ " in common--and two propositions are opposed to one another when they lie quite outside one another. [Cf. 5.513.]

Page 45

The so-called law of induction cannot at any rate be a logical law, for it is evidently a proposition. [See 6.31.]

Page 45

The class of all propositions of the form Fx is the proposition $(x) \phi x$.

Page 45

Does the general form of proposition exist?

Page 45

Yes, if by that is understood the single "logical constant". [Cf. 5.47.]

Page 45

It keeps on looking as if the question "Are there simple things?" made sense. And surely this question must be nonsense!----

Page 45

It would be vain to try and express the pseudo-sentence "Are there simple things?" in symbolic notation.

Page 45

And yet it is clear that I have before me a concept of a thing, of simple correlation, when I think about this matter.

Page 45

But how am I imagining the simple? Here all I can say is always "'x' has reference".--Here is a great riddle!

Page 45

As examples of the simple I always think of points of the visual field (just as parts of the visual field always come before my mind as typical composite objects).

Page 45

Is spatial complexity also logical complexity? It surely seems to be.

Page 45

But what is a uniformly coloured part of my visual field composed of? Of *minima sensibilia*? How should the place of one such be determined?

Page Break 46

Page 46

Even if the sentences which we ordinarily use all contain generalizations, still there must surely occur in them the proto-pictures of the component parts of their special cases. Thus the question remains how we arrive at those.

Page 46

The fact that there is no sign for a particular proto-picture does not show that that proto-picture is not present. Portrayal by means of sign language does not take place in such a way that a *sign* of a proto-picture goes proxy for an *object* of that proto-picture. The sign and the internal relation to what is signified determine the proto-picture of the latter; as the fundamental co-ordinates together with the ordinates determine the points of a figure.

Page 46

A question: can we manage without simple objects in LOGIC?

Page 46

Obviously propositions are possible which contain no simple signs, i.e. no signs which have an immediate reference. And these are really *propositions* making sense, nor do the definitions of their component parts have to be attached to them.

Page 46

But it is clear that components of our propositions can be analysed by means of a definition, and must be, if we want to approximate to the real structure of the proposition. *At any rate, then, there is a process of analysis.* And can it not now be asked whether this process comes to an end? And if so: What will the end be?

Page 46

If it is true that every defined sign signifies *via* its definitions then presumably the chain of definitions must some time have an end. [Cf. 3.261.]

Page 46

The analysed proposition mentions more than the unanalysed.

Page 46

Analysis makes the proposition more complicated than it was, but it cannot and must not make it more complicated than its meaning was from the first.

Page 46

When the proposition is just as complex as its reference, then it is *completely* analysed.

Page 46

But the reference of our propositions is not infinitely complicated.

Page 46

The proposition is the picture of the fact. I can devise different pictures of a fact. (The logical operations serve this purpose.) But

Page Break 47

what is characteristic of the *fact* will be the same in all of these pictures and will not depend on me.

Page 47

With the class of signs of the proposition "p" the class " $\sim p$ ", etc. etc. is already given. As indeed is necessary.

Page 47

But does not that of itself presuppose that the class of all propositions is given us? And how do we arrive at *it*?

11.5.15.

Page 47

Is the logical sum of two tautologies a tautology in the first sense? Is there really such a thing as the duality: tautology--contradiction?

Page 47

The simple thing for us is: the simplest thing that we are acquainted with.---The simplest thing which our analysis can attain--it need appear only as a prototype, as a variable in our propositions---*that* is the simple thing that we mean and look for.

12.5.15.

Page 47

The general concepts (a) of portrayal and (b) of co-ordinates.

Page 47

Supposing that the expression " $\sim(\exists x)x = x$ " were a proposition, namely (say), this one: "There are no things", then it would be matter for great wonder that, in order to express this proposition in symbols, we had to make use of a relation (=) with which it was really not concerned at all.

13.5.15.

Page 47

A singular logical manipulation, the *personification of time*!

Page 47

Just don't pull the knot tight before being certain that you have got hold of the right end.

Page 47

Can we regard a part of space as a thing? In a certain sense we obviously always do this when we talk of spatial things.

Page 47

For it seems--at least so far as I can see at present--that the matter is not settled by getting rid of names by means of definitions: complex spatial objects, for example, seem to me in some sense to be essentially things--I as it were see them as things.--And the designation of them by means of names seems to be more than a mere trick of language. Spatial complex objects--for example--really, so it seems, do appear as things.

Page 47

But what does all that signify?

Page Break 48

Page 48

At any rate that we quite instinctively designate those objects by means of names.--

14.5.15.

Page 48

Language is a part of our organism, and no less complicated than it. [*Cf.* 4.002.]

Page 48

The old problem of complex and fact!

15.5.15.

Page 48

The theory of the complex is expressed in such propositions as: "If a proposition is true then Something exists"; there seems to be a difference between the fact expressed by the proposition: a stands in the relation R to b, and the complex: *a in the relation R to b*, which is just that which "exists" if that proposition is true. It seems as if we could *designate* this Something, and what's more with a real "complex sign".--The feelings expressed in these sentences are quite natural and unartificial, so there must be some truth at the bottom of them. But what truth?

Page 48

What depends on my life?

Page 48

So much is clear, that a complex can only be given by means of its description; and this description will hold or not hold. [See 3.24.]

Page 48

The proposition dealing with a complex will not be nonsensical if the complex does not exist, but simply false. [See 3.24.]

16.5.15.

Page 48

When I see space do I see all its points?

Page 48

It is no more possible to present something "contradicting logic" in language than to present a figure contradicting the laws of space in geometry by means of its coordinates, or, say, to give the coordinates of a point that does not exist. [3.032.]

Page 48

If there were propositions asserting the existence of proto-pictures they would be unique and would be a kind of "logical propositions" and the set of these propositions would give logic an impossible reality. There would be co-ordination in logic.

18.5.15.

Page 48

The possibility of all similes, of the whole pictorial character of our language, is founded in the logic of portrayal. [4.015.]

Page Break 49

19.5.15.

Page 49

We can even conceive a body apprehended as in movement, *and together with its movement*, as a thing. So the moon circling round the earth moves round the sun. Now here it seems clear that this reification is nothing but a logical manipulation--though the possibility of this may be extremely significant.

Page 49

Or let us consider reifications like: a tune, a spoken sentence.--

Page 49

When I say "'x' has reference" do I have the feeling: "it is impossible that 'x' should stand for, say, this knife or this letter"? Not at all. On the contrary.

20.5.15.

Page 49

A complex just is a thing!

21.5.15.

Page 49

We can quite well give a spatial representation of a set of circumstances which contradict the laws of physics, but not of one contradicting the laws of geometry. [3.0321.]

22.5.15.

Page 49

The mathematical notation for infinite series like

$$"1 + x/1! + x^2/2! + \dots"$$

together with the dots is an example of that extended generality. A law is given and the terms that are written down serve as an illustration.

Page 49

In this way instead of (x)fx one might write "fx.fy....".

Page 49

Spatial and *temporal* complexes.

23.5.15.

Page 49

The limits of my language mean the limits of my world. [5.6]

Page 49

There really is only one world soul, which I for preference call *my* soul and as which alone I conceive what I call the souls of others.

Page 49

The above remark gives the key for deciding the way in which solipsism is a truth. [See 5.62.]

Page 49

I have long been conscious that it would be possible for me to write a book: "The world I found". [Cf. 5.631.]

Page 49

The feeling of the simple relation which always comes before our mind as the main ground for the assumption of "simple objects"--

Page Break 50

haven't we got this very same feeling when we think of the relation between name and complex object?

Page 50

Suppose the complex object is this book. Let it be called "A". Then surely the occurrence of "A" in the proposition shews the occurrence of the book in the fact. *For it is not arbitrarily resolved even when it is analysed, so as, e.g., to make its resolution a completely different one in each propositional formation.*----[See 3.3442.]

Page 50

And like the occurrence of the name of a thing in different propositions, the occurrence of the name of compounded objects shews that there is a form and a content in common.

Page 50

In spite of this the *infinitely* complex situation seems to be a chimera.

Page 50

But it also seems certain that we do not infer the existence of simple objects from the existence of particular simple objects, but rather know them--by description, as it were--as the end-product of analysis, by means of a process that leads to them.

Page 50

For the very reason, that a bit of language is nonsensical, it is still possible to go on using it--see the last remark.

Page 50

In the book "The world I found" I should also have to report on my body and say which members are subject to my will, etc. For this is a way of isolating the subject, or rather of skewing that in an important sense there is no such thing as the subject; for it would be the one thing that could *not* come into this book. [See 5.631.]

24.5.15.

Page 50

Even though we have no acquaintance with simple objects we *do* know complex objects by acquaintance, we know by acquaintance that they are complex.--And that in the end they must consist of simple things?

Page 50

We single out a part of our visual field, for example, and we see that it is always complex, that any part of it is still complex but is already simpler, and so on----.

Page 50

Is it imaginable that--e.g.--we should *see* that *all the pointy of a surface are yellow*, without seeing any *single* point of this surface? It almost seems to be so.

Page 50

The way problems arise: the pressure of a tension which then concentrates into a question, and becomes objective.

Page Break 51

Page 51

How should we describe, e.g., a surface uniformly covered with blue?

Page 51

Does the visual image of a *minimum visibile* actually appear to us as indivisible? What has extension is divisible. Are there parts in our visual image that have no extension? E.g., the images of the fixed stars?--

Page 51

The urge towards the mystical comes of the non-satisfaction of our wishes by science. We *feel* that even if all *possible* scientific questions are answered *our problem is still not touched at all*. Of course in that case there are no questions any more; and that is the answer. [Cf. 6.52.]

Page 51

The tautology is asserted, the contradiction denied, by *every* proposition. (For one could append 'and' and some tautology to any proposition without altering its sense; and equally the negation of a contradiction.)

Page 51

And "without altering its sense" means: without altering the *essential* thing about the sign itself. For: the *sign* cannot be altered without altering its sense. [Cf. 4.465.]

Page 51

"aRa" *must* make sense if "aRb" makes sense.

26.5.15.

Page 51

But how am I to explain the general nature of the *proposition* now? We can indeed say: everything that is (or is not) the case can be pictured by means of a proposition. But here we have the expression "*to be the case*"! It is just as problematic.

Page 51

Objects form the counterpart to the proposition.

Page 51

Objects I can only *name*. Signs go proxy for them. [See 3.221.]

27.5.15.

Page 51

I can only speak *of* them, I cannot express them. [See 3.221.]

Page 51

"But might there not be something which cannot be expressed by a *proposition* (and which is also not an object)?" In that case this could not be expressed by means of *language*; and it is also impossible for us to *ask* about it.

Page 51

Suppose there is something outside the *facts*? Which our propositions are impotent to express? But here we do have, e.g., *things and we feel no demand at all* to express them in propositions.

Page Break 52

Page 52

What cannot be expressed we do not express----. And how try to *ask* whether THAT can be expressed which cannot be EXPRESSED?

Page 52

Is there no domain outside the facts?

28.5.15.

Page 52

"Complex sign" and "proposition" are *equivalent*.

Page 52

Is it a tautology to say: *Language* consists of *sentences*?

Page 52

It seems it *is*.

29.5.15.

Page 52

But is *language*: the *only* language?

Page 52

Why should there not be a mode of expression through which I can talk *about* language in such a way that it can appear to me in co-ordination with something else?

Page 52

Suppose that music were such a mode of expression: then it is at any rate characteristic of *science* that *no*

musical themes can occur in it.

Page 52

I myself only write *sentences* down here. And why?

Page 52

How is language unique?

30.5.15.

Page 52

Words are like the film on deep water.

Page 52

It is clear that it comes to the same thing to ask what a sentence is, and to ask what a fact is--or a complex.

Page 52

And why should we not say: "There are complexes; one can use names to name them, or propositions to portray them"?

Page 52

The name of a complex functions in the proposition like the name of an object that I only know by *description*.----The proposition that depicts it functions as a description.

Page 52

But if there are simple objects, is it correct to call both the signs for them and those other signs "names"?

Page 52

Or is "name" so to speak a *logical* concept?

Page 52

"It signalises what is common to a form and a content."----

Page 52

According to the difference in the structure of the complex its name denotes in a different way and is subject to different syntactical laws.

Page Break 53

Page 53

The mistake in this conception must lie in its, on the one hand, contrasting complexes and simple objects, while on the other hand it treats them as akin.

Page 53

And yet: *Components* and *complex* seem to be akin, *and* to be opposed to one another.

Page 53

(Like the plan of a town and the map of a country which we have before us, the same size and on different scales.)

Page 53

What is the source of the feeling "I can correlate a name with all that I see, with this landscape, with the dance of motes in the air, with all this; indeed, what should we call a name if not this"?!

Page 53

Names signalise what is common to a single form and a single content.--Only *together with* their syntactical use do they signalise *one particular* logical form. [*Cf.* 3.327.]

31.5.15.

Page 53

One cannot achieve any more by using names in describing the world than by means of the general description of the world!!!

Page 53

Could one then manage without names? Surely not.

Page 53

Names are necessary for an assertion that *this* thing possesses *that* property and so on.

Page 53

They link the propositional form with quite definite objects.

Page 53

And if the general description of the world is like a stencil of the world, the names pin it to the world so that the world is wholly covered by it.

1.6.15.

Page 53

The great problem round which everything that I write turns is: Is there an order in the world *a priori*, and if

so what does it consist in?

Page 53

You are looking into fog and for that reason persuade yourself that the goal is already close. But the fog disperses and the goal is not yet in sight.

2.6.15.

Page 53

I said: "A tautology is asserted by every proposition"; but that is not enough to tell us why it is not a *proposition*. For has it told us *why* a proposition cannot be asserted by p and $\sim p$?

Page 53

For my theory does not really bring it out that the proposition *must* have two poles.

Page Break 54

Page 54

For what I should now have to do is to find an expression in the language of this theory for HOW MUCH *a proposition says*. And this would have to yield the result that tautologies say NOTHING.

Page 54

But how can we find the measure of amount-that-is-said?

Page 54

At any rate it is there; and our theory *must* be able to give it expression.

3.6.15.

Page 54

One could certainly say: *That* proposition says the most from which the most follows.

Page 54

Could one say: "From which the most mutually independent propositions follow"?

Page 54

But doesn't it work like this: If p follows from q but not q from p , then q says more than p ?

Page 54

But now nothing at all follows from a tautology.----It however follows from every proposition. [Cf. 5.142.]

Page 54

The analogous thing holds of its opposite.

Page 54

But then! Won't contradiction now be the proposition that says the most? From " $p \sim p$ " there follows not merely " p " but also " $\sim p$ "! Every proposition follows from them and they follow from none!? But I surely can't infer anything from a contradiction, just *because* it is a contradiction.

Page 54

But if contradiction is the class of *all propositions*, then tautology becomes what is common to any classes of propositions that have nothing in common and vanishes completely. [Cf. 5.143.]

Page 54

" $p \vee \sim p$ " would then be a sign only in appearance. But in reality the dissolution of the proposition.

Page 54

The tautology as it were vanishes inside all propositions, the contradiction outside all propositions. [See 5.143.]

Page 54

In these investigations I always seem to be unconsciously taking the elementary proposition as my starting point.--

Page 54

Contradiction is the outer limit of propositions; no proposition asserts it. Tautology is their substanceless centre. (The middle point of a circle can be conceived as its inner boundary.) [Cf. 5.143.]

Page 54

(The key word still hasn't yet been spoken.)

Page Break 55

Page 55

The thing is that here it is very easy to confuse the logical product and the logical sum.

Page 55

For we come to the apparently remarkable result that two propositions must have something in common in order to be capable of being asserted by one proposition.

Page 55
(Belonging to a single class, however, is also something that propositions can have in *common*.)

Page 55
(Here there is still a definite and decisive lack of clarity in my theory. Hence a certain feeling of dissatisfaction')

4.6.15.

Page 55
"p.q" only makes sense if "p \vee q" makes sense.

5.6.15.

Page 55
"p.q" asserts "p" and "q" but that surely does not mean that "p.q" is the common component of "p" and "q", but on the contrary that "p" and also "q" are equally contained in "p.q".

Page 55
In this sense p and \sim p would have something in common, for example propositions like \sim p \vee q and p \vee q. That is: there are indeed propositions which are asserted by "p" as well as by " \sim p"--e.g. the above ones--but there are none that assert p as well as also asserting \sim p.

Page 55
In order for a proposition to be capable of being true it must also be capable of being false.

Page 55
Why does tautology say nothing? Because every possibility is admitted in it in advance; because.....

Page 55
It must shew *in the proposition itself* that it says *something* and in the tautology that it says nothing.

Page 55
p. \sim p is that thing--perhaps *that nothing*--that p and \sim p have in common.

Page 55
In the *real* sign for p there is already contained the sign "p \vee q". (For it is then possible to form this sign WITHOUT FURTHER ADO.)

6.6.15.

Page 55
(This theory treats of propositions exclusively, so to speak, as a world on their own and not in connexion with what they present.)

Page 55
The connexion of the picture-theory with the class-theory \dagger 1 will only become quite obvious later.

Page 55
One cannot say of a tautology that it is true, for it is *made so as to be true*.

Page Break 56

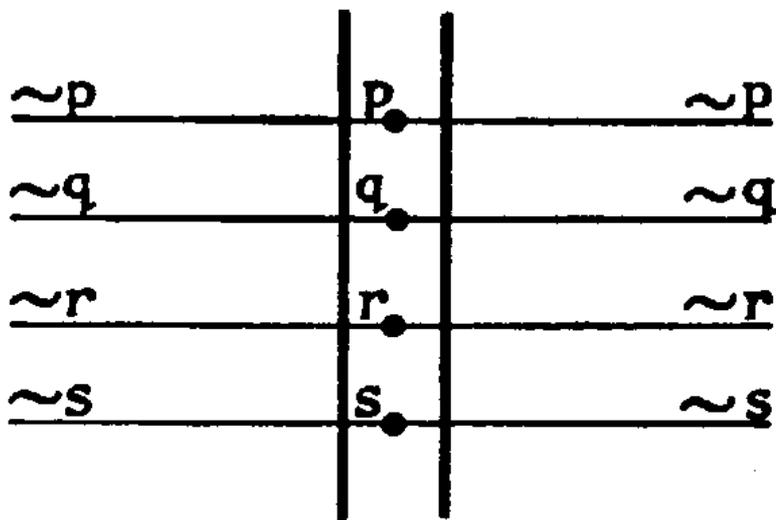

Page 56
It is not a picture of reality, in the sense that it does not PRESENT anything; it is what all--mutually contradictory--*pictures* have in common.

Page 56
In the class-theory it is not yet evident why the proposition needs its counter-proposition. Why it is a part of logical space which is *separated* from the remaining part of logical space.

Page 56
The proposition says: *this* is how it is and not: *that*. It presents a possibility and itself *conspicuously* forms one part of a whole,--whose features it bears--and from which it stands out.

Page 56
p \vee q \vee \sim p is also a tautology.----

Page 56
There are certainly propositions that *allow* p as well as \sim p but *none* that *assert* p as well as \sim p.

Page 56

The possibility of " $p \vee q$ " when " p " is given, is a possibility in a different dimension from the impossibility of " $\sim p$ ".

Page 56

" $p \vee \sim p$ " is a QUITE SPECIAL CASE of " $p \vee q$ ".

Page 56

" p " has nothing in common with " $\sim p \vee q$ ".

Page 56

By my attaching the " \sim " to " p " the proposition gets into a different class of propositions.

Page 56

Every proposition has only one negative;... There is only one proposition lying quite outside " p ". [Cf. 5.513.]

Page 56

It could also be said: The proposition which asserts p and $\sim p$ is negated by all propositions; the proposition which asserts p or $\sim p$ is asserted by all propositions.

Page 56

My mistake must lie in my wanting to use what follows from the nature of negation, etc. In its definition.--That " p " and " $\sim p$ " have

Page Break 57

a common boundary is no part of the explanation of negation that I am trying for.

7.6.15.

Page 57

If, e.g., it could be said: All propositions that do not assert p assert $\sim p$, then that would give us an adequate description.--But that doesn't work.

Page 57

But can't we say that " $\sim p$ " is what is common only to such propositions as do not assert " p "? And from this there already follows the impossibility of " $p.\sim p$ ".

Page 57

(All this, of course, already presupposes the existence of the whole *world of propositions*. Rightly?)

Page 57

IT IS NOT ENOUGH to point to $\sim p$'s lying outside p . It will only be possible to derive all the properties of " $\sim p$ " if " $\sim p$ " is introduced *essentially as the negative of p*.

Page 57

But how to do that?--

Page 57

Or is it like this: We cannot "introduce" the proposition $\sim p$ at all, but we encounter it as a *fait accompli* and we can only point to its individual formal properties, as, e.g., that it has nothing in common with p , that no proposition contains it and p , etc. etc.?

8.6.15.

Page 57

Every mathematical proposition is a symbolic representation of a *modus ponens*. (And it is clear that the *modus ponens* cannot be expressed in a proposition.) [Cf. 6.1264.]

p and $\sim p$ have a common boundary: this is expressed by the fact that the negative of a proposition is only determined by means of the proposition itself. For we say: The negative of a proposition is a proposition which... and now follows the relation of $\sim p$ to p .----

9.6.15.

It will, of course, be possible simply to say: The negation of p is the proposition which has no proposition in common with p .

The expression "tertium non datur" is really a piece of nonsense. (For no third thing is in question in $p \vee \sim p$.)

Should we not be able to use this for our definition of the negative of a proposition?

Can't we say: Among all the propositions that are dependent on p alone, there are only such as assert p and such as deny it?

So I can say that the negative of p is the class of all propositions which are dependent on " p " alone and *do not assert "p"*.

10.6.15.

" $p.q \vee \sim q$ " is NOT dependent on " q "!

Whole propositions, to disappear!

The very fact that " $p.q \vee \sim q$ " is independent of " q ", although it obviously contains the written sign " q ", shews us how signs of the form $\eta \vee \sim \eta$ can apparently, but still only *apparently*, exist.

This naturally arises from the fact that this arrangement " $p \vee \sim p$ " is indeed externally possible, but does not satisfy the conditions for such a complex to *say something* and so be a proposition.

" $p.q \vee \sim q$ " says the same as
" $p.r \vee \sim r$ "

--whatever q and r may say--: All tautologies say the same thing. (Namely nothing.) [Cf. 5.43.]

From the last explanation of negation it follows that all propositions which are dependent on p alone and which do not assert p --and only these--negate p . So " $p \vee \sim p$ " and " $p.\sim p$ " are not propositions, for the first sign neither asserts nor denies p and the second would have to affirm both.

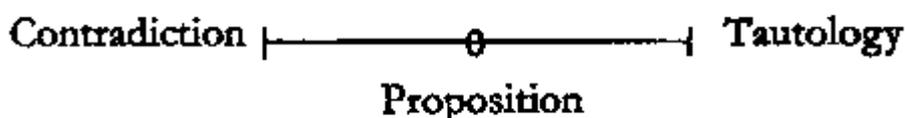

But since I can after all write down $p \vee \sim p$ and $p.\sim p$, particularly in connexion with other sentences, it must be clearly set forth what role these pseudo-propositions have, especially in such connexions. For they are not, of course, to be treated as a completely meaningless appendix--like e.g. a meaningless name. Rather do they belong in the symbolism--like "0" in arithmetic. [Cf. 4.4611.]

Here it is clear that $p \vee \sim p$ has the role of a true proposition, which however says *nought*.

So we have again arrived at the quantity of what is said.

11.6.15.

The opposite of " $p.\sim p$ " follows from all propositions; is that as much as to say that " $p.\sim p$ " says nothing?--By my earlier rule the contradiction would have to say more than all other propositions.

If a proposition saying a great deal is false, it ought to be interesting

that it is false. It is astonishing that the negative of a proposition that says a great deal should say absolutely nothing.

We said: If p follows from q but not q from p, q says more than p. But now, if it follows from p that q is false, but not from q that p is false, what then?

From p there follows $\sim q$, from q not $\sim p$.----?

12.6.15.

In connexion with any proposition it could really be asked: what does it come to for it to be true? What does it come to for it to be false?

Now the 'assumption' in $p.\sim p$ is never anything but false, and so this does not come to anything; and as for what it would amount to if it were true, of course, that can't be asked at all.

13.6.15.

If " $p.\sim p$ " COULD be true it would indeed say a *very* great deal. But the *assumption* that it is true does not come into consideration in connexion with it, as the 'assumption' in it is always false.

Singular, since the words "true" and "false" refer to the relation of the proposition to the world, that these words can be used in the proposition itself for purposes of representation!

We have said: if a proposition depends only on p and it asserts p then it does not negate it, and vice versa: *Is this the picture of that mutual exclusion of p and $\sim p$? Of the fact that $\sim p$ is what lies outside p?*

It seems so! The proposition " $\sim p$ " is in the same sense what lies outside "p".----(Do not forget either that the picture may have very complicated co-ordinates to the world.)

One might simply say: " $p.\sim p$ " says nothing in the proper sense of the word. For in advance there is no possibility left which it can *correctly* present.

Incidentally, if "p follows from q" means: If q is true then p must be true, then it cannot be said at all that anything follows from " $p.\sim p$ ", since there is no such thing as the hypothesis that " $p.\sim p$ " is true.

14.6.15.

We have become clear, then, that names may and do stand for the most various forms, and that it is only the syntactical application that signalises the form that is to be presented.

Now what is the syntactical application of names of simple objects?

What is my fundamental thought when I talk about simple objects? Do not 'complex objects' in the end satisfy just the demands which I

apparently make on the simple ones? If I give this book a name "N" and now talk about N, is not the relation of N to that 'complex object', to those forms and contents, *essentially* the same as I imagined only between name and simple object?

For N.B.: even if the name "N" vanishes on further analysis, still it indicates a *single common* thing.

But what about the reference of names out of the context of the proposition?

The question might however also be presented like this: It seems that the idea of the SIMPLE is already to be found contained in that of the complex and in the idea of analysis, and in such a way that we come to this idea quite

apart from any examples of simple objects, or of propositions which mention them, and we realize the existence of the simple object--*a priori*--as a logical necessity.

Page 60

So it looks as if the existence of the simple objects were related to that of the complex ones as the sense of $\sim p$ is to the sense of p : the *simple* object is *prejudged* in the complex.

15.6.15.

Page 60

(This is NOT to be confused with the *fact* that its *component* is prejudged in the complex.)

Page 60

(One of the most difficult of the philosopher's tasks is to find out where the shoe pinches.)

Page 60

It is quite clear that I can in fact correlate a name with this watch just as it lies here ticking in front of me, and that this name will have reference outside any proposition in the very sense I have always given that word, and I feel that that name in a proposition will correspond to all the requirements of the 'names of simple objects'.

16.6.15.

Page 60

Now we just want to see whether this watch in fact corresponds to all the conditions for being a 'simple object'.----

Page 60

The question is really this: In order to know the syntactical treatment of a name, must I know the composition of its reference? If so, then the whole composition is already expressed even in the unanalysed proposition....

Page 60

(One often tries to jump over too wide chasms of thought and then falls in.)

Page Break 61

Page 61

What seems to be given us *a priori* is the concept: *This.*--Identical with the concept of the *object*.

Page 61

Relations and properties, etc. are *objects* too.

Page 61

My difficulty surely consists in this: In all the propositions that occur to me there occur names, which, however, must disappear on further analysis. I know that such a further analysis is possible, but am unable to carry it out completely. In spite of this I certainly seem to know that if the analysis were completely carried out, its result would have to be a proposition which once more contained names, relations, etc. In brief it looks as if in this way I knew a form without being acquainted with any single example of it.

Page 61

I see that the analysis can be carried farther, and can, so to speak, not imagine its leading to anything different from the species of propositions that I am familiar with.

Page 61

When I say this watch is shiny, and what I mean by this watch alters its composition in the smallest particular, then this means not merely that the sense of the sentence alters in its content, but also *what I am saying about this watch* straightway alters its sense. The whole form of the proposition alters.

Page 61

That is to say, the syntactical employment of the names completely characterizes the form of the complex objects which they denote.

Page 61

Every proposition that has a sense has a COMPLETE sense, and it is a picture of reality in such a way that what is not yet said in it simply cannot belong to its sense.

Page 61

If the proposition "this watch is shiny" has a sense, it must be explicable HOW THIS proposition has THIS sense.

Page 61

If a proposition tells us something, then it must be a picture of reality just as it is, and a complete picture at that.----There will, of course, also be something that it does *not* say--but what it does say it says completely and it must be susceptible of SHARP definition.

Page 61

So a proposition may indeed be an incomplete picture of a certain fact, but it is ALWAYS *a complete picture*. [Cf. 5.156.]

Page 61

From this it would now seem as if in a certain sense all names were *genuine names*. Or, as I might also say, as if all objects were in a certain sense simple objects.

Page Break 62

17.6.15.

Page 62

Let us assume that every spatial object consists of infinitely many points, then it is clear that I cannot mention all these by name when I speak of that object. Here then would be a case in which I *cannot* arrive at the complete analysis in the old sense at all; and perhaps just this is the usual case.

Page 62

But this is surely clear: the propositions which are the only ones that humanity uses will have a sense just as they are and do not wait upon a future analysis in order to acquire a sense.

Page 62

Now, however, it seems to be a legitimate question: Are--e.g.--spatial objects composed of simple parts; in analysing them, does one arrive at parts that cannot be further analysed, or is this not the case?

Page 62

--But what kind of question is this?--

Page 62

Is it, A PRIORI, clear that in analysing we must arrive at simple components--is this, e.g., involved in the concept of analysis--, or is analysis *ad infinitum* possible?--Or is there in the end even a third possibility?

Page 62

This question is a logical one and the complexity of spatial objects is a logical complexity, for to say that one thing is part of another is always a tautology.

Page 62

But suppose, for example, that I wanted to say that ONE component of a fact had a particular property? Then I should have to mention it by name and use a logical sum.

Page 62

And nothing seems to speak against infinite divisibility.

Page 62

And it keeps on forcing itself upon us that there is some simple indivisible, an element of being, in brief a thing.

Page 62

It does not go against our feeling, that *we* cannot analyse PROPOSITIONS so far as to mention the elements by name; no, we feel that the WORLD must consist of elements. And it appears as if that were identical with the proposition that the world must be what it is, it must be definite. Or in other words, what vacillates is our determinations, not the world. It looks as if to deny things were as much as to say that the world can, as it were, be indefinite in some such sense as that in which our knowledge is uncertain and indefinite.

Page 62

The world has a fixed structure.

Page Break 63

Page 63

Is the representation by means of unanalysable names *only one system*?

Page 63

All I want is only for *my meaning* to be completely analysed!

Page 63

In other words the proposition must be completely articulated. Everything that its sense has in common with another sense must be contained separately in the proposition. If generalizations occur, then the forms of the particular cases must be manifest and it is clear that this demand is justified, otherwise the proposition cannot be a picture at all, of *anything*. [Cf. 3.251.]

Page 63

For if possibilities *are left open* in the proposition, *just this* must be *definite*: *what* is left open. The generalizations of the form--e.g.--must be definite. What I do not know I do not know, but the proposition must shew me WHAT I know. And in that case, is not this *definite* thing at which I *must* arrive precisely simple in that

sense that I have always had in mind? It is, so to speak, what is hard.

Page 63

In that case, then, what we mean by "complex objects do not exist" is: It must be clear in the proposition how the object is composed, so far as it is possible for us to speak of its complexity at all.--The sense of the proposition must appear in the proposition as divided into its *simple* components--. And these parts are then actually indivisible, for further divided they just would not be THESE. In other words, the proposition can then no longer be *replaced* by one that has more components, but any that has more components also does not have *this* sense.

Page 63

When the sense of the proposition is completely expressed in the proposition itself, the proposition is always divided into its simple components--no further division is possible and an apparent one is superfluous--and these are objects in the original sense.

18.6.15.

Page 63

If the complexity of an object is definitive of the sense of the proposition, then it must be portrayed in the proposition to the extent that it does determine the sense. And to the extent that its composition is *not* definitive of *this* sense, to this extent the objects of this proposition are *simple*. THEY *cannot* be further divided.----

Page 63

The demand for simple things *is* the demand for definiteness of sense. [Cf. 3.23.]

Page 63

---For if I am talking about, e.g., this watch, and mean something complex by that and nothing depends upon the way it is compounded,

Page Break 64

then a generalization will make its appearance in the proposition and the fundamental forms of the generalization will be completely determinate *so far as they are given at all*.

Page 64

If there is a final sense and a proposition expressing it completely, then there are also names for simple objects.

Page 64

That is the correct designation.

Page 64

But suppose that a simple name denotes an infinitely complex object? For example, perhaps we assert of a patch in our visual field that it is to the right of a line, and we assume that every patch in our visual field is infinitely complex. Then if we say that a point in that patch is to the right of the line, this proposition follows from the previous one, and if there are infinitely many points in the patch *then infinitely many propositions of different content follow LOGICALLY from that first one*. And this of itself shews that the proposition itself was as a matter of fact infinitely complex. That is, not the propositional sign by itself, but *it together with its syntactical application*.

Page 64

Now it seems, of course, *perfectly* possible that in reality infinitely many different propositions do *not* follow from such a proposition, because our visual field perhaps--or probably--does not consist of infinitely many parts--but continuous visual space is only a subsequent construction--; and in that case only a finite number of propositions follow from the one known and it itself is *finite* in every sense.

Page 64

But now, does not this *possible* infinite complexity of the sense impair its definiteness?

Page 64

We might demand definiteness in this way too!: if a proposition is to make sense then the syntactical employment of each of its parts must be settled in advance.--It is, e.g., not possible *only subsequently to come upon* the fact that a proposition follows from it. But, e.g., what propositions follow from a proposition must be completely settled before that proposition can have a sense!

Page 64

It seems to me perfectly possible that patches in our visual field are simple objects, in that we do not perceive any single point of a patch separately; the visual appearances of stars even seem certainly to be so. What I mean is: if, e.g., I say that this watch is not in the drawer, there is absolutely no need for it to FOLLOW LOGICALLY that a wheel which is in the watch is not in the drawer, for perhaps *I had not the least knowledge* that the wheel was in the watch, and hence

could not have meant by "this watch" the complex in which the wheel occurs. And it is certain--moreover--that I do not see all the parts of my *theoretical* visual field. Who knows *whether* I see infinitely many points?

Let us suppose that we were to see a circular patch: is the circular form its *property*? Certainly not. It seems to be a structural "property". And if I notice that a spot is round, am I not noticing an infinitely complicated structural property? Or I notice only that the spot has finite extension, and this of itself seems to *presuppose* an infinitely complex structure.

Not: One proposition follows from another, but the truth of the one follows from the truth of the other. (That is why it *follows* from "All men are mortal" that "If Socrates is a man, then he is mortal.")

A proposition can, however, quite well treat of infinitely many points without being infinitely complex in a particular sense.

19.6.15.

When we see that our visual field is complex we also see that it consists of *simpler* parts.

We can talk of functions of this and that kind without having any particular application in view.

For we don't have any examples before our minds when we use Fx and all the other variable form-signs.

In short: if we were to apply the prototypes only in connexion with names, there would be the possibility that we should know the existence of the prototypes from the existence of their special cases. But as it is we use *variables*, that is to say we talk, so to speak, of the prototypes by themselves, quite apart from any individual cases.

We portray the thing, the relation, the property, by means of variables and so shew that we do not derive these ideas from particular cases that occur to us, but possess them somehow *a priori*.

For the question arises: If the individual forms are, so to speak, given me in experience, then I surely can't make use of them in logic; in that case I cannot write down an x or a ϕy . But this I can surely not avoid at all.

An incidental question: Does logic deal with certain classes of functions and the like? And if not, what then is the import of Fx , ϕz , and so on in logic?

Then these must be signs of more general import!

There doesn't after all seem to be any setting up of a kind of logical inventory as I formerly imagined it.

The component parts of the proposition must be simple = The proposition must be completely articulated. [Cf. 3.251.]

But now does this SEEM to contradict the facts?----

For in logic we are apparently trying to produce ideal pictures of articulated propositions. But how is that possible?

Or can we deal with a proposition like "The watch is on the table" without further ado according to the rules of logic? No, here we say, for example, that no date is given in the proposition, that the proposition is only apparently... etc. etc.

So before we can deal with it we must, so it seems, transform it in a particular way.

But perhaps this is not conclusive, for could we not just as well apply our usual *logical* notation to the special proposition?

Page 66

Yes, this is the point: Can we justly apply logic just as it stands, say in *Principia Mathematica*, straightaway to *ordinary propositions*?

Page 66

Of course we cannot disregard what is *expressed* in our propositions by means of endings, prefixes, vowel changes, etc. etc.

Page 66

But we do apply mathematics, and with the greatest success, to ordinary propositions, namely to those of physics.

Page 66

But how remarkable: in the familiar theorems of mathematical physics there appear neither things nor functions nor relations nor any other logical forms of object! Instead of things what we have here is numbers, and the functions and relations are purely mathematical throughout)

Page 66

But it is surely a fact that these propositions are applied to solid reality.

Page Break 67

Page 67

The variables in those theorems do not--as is often said--stand for lengths, weights, time intervals, etc. at all, they simply stand for numbers and for nothing else.

Page 67

When, however, I want to apply numbers, I come to relations, things, etc. etc. I say, e.g.: This length is 5 yards and here I am talking of relations and things, and in the *completely ordinary* sense at that.

Page 67

Here we come to the question about the reference of variables in the propositions of physics. For these are not tautologies.

Page 67

A proposition of physics is obviously senseless if its application is not given. What sort of sense would it make to say: "k = m.p"?

Page 67

So the complete physical proposition does after all deal with things, relations and so on. (Which was really to be expected.)

Page 67

Now everything turns on the fact that I apply numbers to ordinary things, etc., which in fact says no more than that numbers occur in our quite ordinary sentences.

Page 67

The difficulty is really this: even when we want to express a *completely definite* sense there is the possibility of failure. So it seems that we have, so to speak, no guarantee that our proposition is really a picture of reality.

Page 67

The division of the body into *material points*, as we have it in physics, is nothing more than analysis into *simple components*.

Page 67

But could it be possible that the sentences in ordinary use have, as it were, only an incomplete sense (quite apart from their truth or falsehood), and that the propositions in physics, as it were, approach the stage where a proposition really has a complete sense?

Page 67

When I say, "The book is lying on the table", does this really have a completely clear sense? (An EXTREMELY important question.)

Page 67

But the sense must be clear, for after all we mean *something* by the proposition, and as much as we *certainly* mean must surely be clear.

Page 67

If the proposition "The book is on the table" has a clear sense, then I must, whatever *is the case*, be able to say whether the proposition is true or false. There could, however, very well occur *cases* in which I should not be able to say straight off whether the book is still to be called "lying on the table". Then--?

Then is the case here one of my knowing exactly what I want to say, but then making mistakes in expressing it?

Or can this uncertainty TOO be included in the proposition?

But it may also be that the proposition "The book is lying on the table" represents my sense completely, but that I am using the words, e.g., "lying on", with a *special* reference here, and that elsewhere they have another reference. What I mean by the verb is perhaps a quite special relation which the book now actually has to the table.

Then are the propositions of physics and the propositions of ordinary life at bottom equally sharp, and does the difference consist only in the more consistent application of signs in the language of science?

Is it or is it not possible to talk of a proposition's having a more or less sharp sense?

It seems clear that what we MEAN must always be "*sharp*".

Our expression of what we mean can in its turn only be right or wrong. And further the words can be applied consistently or inconsistently. There does not seem to be any other possibility.

When I say, e.g., that the table is a yard long, it is extremely questionable what I mean by this. But I presumably mean that the distance between THESE two points is a yard, and that the points belong to the table.

We said that mathematics has already been applied with success to ordinary propositions, but in propositions of physics it treats of completely different objects from those of our ordinary language. Must our propositions undergo *such* preparation, to make them capable of being dealt with mathematically? Evidently they must. When quantities come in question, then an expression like, e.g., "the length of this table" would not be adequate. This length would have to be defined, say, as the distance between two surfaces, etc. etc.

Mathematical sciences are distinguished from non-mathematical ones by treating of things of which ordinary language does not speak, whereas the latter talk about things that are generally familiar.

21.6.15.

Our difficulty was that we kept on speaking of simple objects and were unable to mention a single one.

If a point in space does not exist, then its co-ordinates do not exist either, and if the coordinates exist then the point exists too.--That's how it is in logic.

The simple sign is *essentially simple*.

It functions as a simple object. (What does that mean?)

Its composition becomes completely *indifferent*. It disappears from view.

It always looks as if there were complex objects functioning as simples, and then also really simple ones, like the material points of physics, etc..

It can be seen that a name stands for a complex object from an indefiniteness in the proposition in which it occurs. This comes of the generality of such propositions. We *know* that not everything is yet determined by this proposition. For the generality notation *contains* a proto-picture. [Cf. 3.24.]

All invisible masses, etc. etc. must come under the generality notation.

What is it for propositions to approximate to the truth?

But logic as it stands, e.g., in *Principia Mathematica* can quite well be applied to our ordinary propositions, e.g., from "All men are mortal" and "Socrates is a man" there follows according to this logic "Socrates is mortal" which is obviously correct although I equally obviously do not know what structure is possessed by the thing Socrates or the property of mortality. Here they just function as simple objects.

Obviously the circumstance that makes it possible for certain forms to be projected by means of a definition into a name, guarantees of itself that this name can then also be treated as a real one.

To anyone that sees clearly, it is obvious that a proposition like "This watch is lying on the table" contains a lot of indefiniteness, in spite of its form's being completely clear and simple in outward appearance. So we see that this simplicity is only constructed.

22.6.15.

It is then also clear to *the UNPREJUDICED mind* that the sense of the proposition "The watch is lying on the table" is more complicated than the proposition itself.

The conventions of our language are extraordinarily complicated. There is enormously much added in thought to each proposition and not said. (These conventions are exactly like Whitehead's 'Conventions'. They are definitions with *a certain generality of form.*) [Cf. 4.002.]

I only want to justify the vagueness of ordinary sentences, for it *can* be justified.

It is clear that *I know* what I *mean* by the vague proposition. But now someone else doesn't understand and says: "Yes, but if you mean that then you should have added such and such"; and now someone else again will not understand it and will demand that the proposition should be given in more detail still. I shall then reply: NOW THAT can *surely* be taken for granted.

I tell someone "The watch is lying on the table" and now he says: "Yes, but if the watch were in such-and-such a position would you still say it was lying on the table?" And I should become uncertain. This shews that I did not know what I meant by "lying" *in general*. If someone were to drive me into a corner in this way in order to shew that I did not know what I meant, I should say: "*I know* what I mean; I mean just THIS", pointing to the appropriate complex with my finger. And in this complex I do actually have the two objects in a relation.----But all that this *really* means is: The fact can SOMEHOW be portrayed by means of this form too.

Now when I do this and designate the objects by means of *names*, does that make them simple?

All the same, however, this proposition is a picture of that complex.

This object is *simple* for me!

If, e.g., I call some rod "A", and a ball "B", I can say that A is leaning against the wall, but not B. Here the internal nature of A and B comes into view.

A name designating an object thereby stands in a relation to it which is wholly determined by the logical kind of the object and which signalises that logical kind.

And it is clear that the object must be of a particular logical kind, it just is as complex, or as simple, as it is.

"The watch *is sitting* on the table" is senseless!

Only the complex part of the proposition can be true or false.

The name compresses its whole complex reference into one.

15.4.16.

Page 71

We can only foresee what we ourselves construct. [See 5.556.]

Page 71

But then where is the concept of a simple object still to be found?

Page 71

This concept does not so far come in here at all.

Page 71

We must be able to construct the simple functions because we must be able to give each sign a meaning.

Page 71

For the only sign which guarantees its meaning is function and argument.

16.4.16.

Page 71

Every simple proposition can be brought into the form ϕx .

Page 71

That is why we may compose all simple propositions from this form.

Page 71

Suppose that *all* simple propositions were given me: then it can simply be asked what propositions I can construct from them. And these are *all* propositions and this is *how* they are *bounded*. [4.51.]

Page 71

(p): $p = aRx.xRy... zRb$

Page 71

(p): $p = aRx$

17.4.16.

Page 71

The above definition can in its general form only be a rule for a written notation which has nothing to do with the sense of the signs.

Page 71

But can there be such a rule?

Page 71

The definition is only possible if it is itself not a proposition.

Page 71

In that case a proposition cannot treat of all propositions, while a definition can.

23.4.16.

Page 71

The above definition, however, just does not deal with all propositions, for it essentially contains real variables. It is quite analogous to an operation whose own result can be taken as its base.

26.4.16.

Page 71

In this way, and in this way alone, is it possible to proceed from one type to another. [Cf. 5.252.]

Page 71

And we can say that all types stand in hierarchies.

Page Break 72

Page 72

And the hierarchy is only possible by being built up by means of operations.

Page 72

Empirical reality is bounded by the number of objects.

Page 72

The boundary turns up again in the totality of simple propositions. [See 5.5561.]

Page 72

The hierarchies are and must be independent of reality. [See 5.5561.]

Page 72

The meanings of their terms are only determined by the correlation of objects and names.

27.4.16.

Page 72

Say I wanted to represent a function of three non-interchangeable arguments.

$\phi(x): \phi(), x$

Page 72

But should there be any mention of non-interchangeable arguments in logic? If so, this surely presupposes something about the character of reality.

6.5.16.

Page 72

At bottom the whole *Weltanschauung* of the moderns involves the illusion that the so-called laws of nature are explanations of natural phenomena. [6.371.]

Page 72

In this way they stop short at the laws of nature as at something *impregnable* as men of former times did at God and fate. [See 6.372.]

Page 72

And both are right and wrong. The older ones are indeed clearer in the sense that they acknowledge a clear terminus, while with the new system it is supposed to look as if *everything* had a foundation. [See 6.372.]

11.5.16.

Page 72

$|p \quad |(a, a)$

Page 72

There are also operations with two bases. And the "|" -operation is of this kind.

Page 72

$|(\xi, \eta)...$ is an arbitrary term of the series of results of as operation.
 $(\exists x). \phi x$

Page 72

Is $(\exists x)$ etc. really an operation?

Page 72

But what would be its base?

11.6.16.

Page 72

What do I know about God and the purpose of life?

Page 72

I know that this world exists.

Page Break 73

Page 73

That I am placed in it like my eye in its visual field.

Page 73

That something about it is problematic, which we call its meaning.

Page 73

That this meaning does not lie in it but outside it. [Cf. 6.41.]

Page 73

That life is the world. [Cf. 5.621.]

Page 73

That my will penetrates the world.

Page 73

That my will is good or evil.

Page 73

Therefore that good and evil are somehow connected with the meaning of the world.

Page 73

The meaning of life, i.e. the meaning of the world, we can call God.

And connect with this the comparison of God to a father.

Page 73

To pray is to think about the meaning of life.

Page 73

I cannot bend the happenings of the world to my will: I am completely powerless.

Page 73

I can only make myself independent of the world--and so in a certain sense master it--by renouncing any influence on happenings.

5.7.16.

Page 73

The world is independent of my will. [6.373.]

Page 73

Even if everything that we want were to happen, this would still only be, so to speak, a grace of fate, for what would guarantee it is not any logical connexion between will and world, and we could not in turn will the supposed physical connexion. [6.374.]

Page 73

If good or evil willing affects the world it can only affect the boundaries of the world, not the facts, what cannot be portrayed by language but can only be shewn in language. [Cf. 6.43.]

Page 73

In short, it must make the world a wholly different one. [See 6.43.]

Page 73

The world must, so to speak, wax or wane as a whole. As if by accession or loss of meaning. [Cf. 6.43.]

Page 73

As in death, too, the world does not change but stops existing. [6.431.]

6.7.16.

Page 73

And in this sense Dostoievsky is right when he says that the man who is happy is fulfilling the purpose of existence.

Page 73

Or again we could say that the man is fulfilling the purpose of existence who no longer needs to have any purpose except to live. That is to say, who is content.

Page Break 74

Page 74

The solution of the problem of life is to be seen in the disappearance of this problem. [See 6.521.]

Page 74

But is it possible for one so to live that life stops being problematic? That one is *living* in eternity and not in time?

7.7.16.

Page 74

Isn't this the reason why men to whom the meaning of life had become clear after long doubting could not say what this meaning consisted in? [See 6.521.]

Page 74

If I can imagine a "*kind* of object" without knowing whether there are such objects, then I must have constructed their proto-picture for myself.

Page 74

Isn't the method of mechanics based on this?

8.7.16.

Page 74

To believe in a God means to understand the question about the meaning of life.

Page 74

To believe in a God means to see that the facts of the world are not the end of the matter.

Page 74

To believe in God means to see that life has a meaning.

Page 74

The world is *given* me, i.e. my will enters into the world completely from outside as into something that is already there.

Page 74

(As for what my will is, I don't know yet.)

Page 74

That is why we have the feeling of being dependent on an alien will.

Page 74

However *this may be*, at any rate we *are* in a certain sense dependent, and what we are dependent on we can call God.

Page 74

In this sense God would simply be fate, or, what is the same thing: The world--which is independent of our will.

Page 74

I can make myself independent of fate.

Page 74

There are two godheads: the world and my independent I.

Page 74

I am either happy or unhappy, that is all. It can be said: good or evil do not exist.

Page 74

A man who is happy must have no fear. Not even in face of death.

Page 74

Only a man who lives not in time but in the present is happy.

Page Break 75

Page 75

For life in the present there is no death.

Page 75

Death is not an event in life. It is not a fact of the world. [Cf. 6.4311.]

Page 75

If by eternity is understood not infinite temporal duration but non-temporality, then it can be said that a man lives eternally if he lives in the present. [See 6.4311.]

Page 75

In order to live happily I must be in agreement with the world. And that is what "being happy" *means*.

Page 75

I am then, so to speak, in agreement with that alien will on which I appear dependent. That is to say: 'I am doing the will of God'.

Page 75

Fear in face of death is the best sign of a false, i.e. a bad, life.

Page 75

When my conscience upsets my equilibrium, then I am not in agreement with Something. But what is this? Is it *the world*?

Page 75

Certainly it is correct to say: Conscience is the voice of God.

Page 75

For example: it makes me unhappy to think that I have offended such and such a man. Is that my conscience?

Page 75

Can one say: "Act according to your conscience whatever it may be"?

Page 75

Live happy!

9.7.16.

Page 75

If the most general form of proposition could not be given, then there would have to come a moment where we suddenly had a new experience, so to speak a logical one.

Page 75

That is, of course, impossible.

Page 75

Do not forget that $(\exists x)fx$ does not mean: There is an x such that fx , but: There is a true proposition " fx ".

Page 75

The proposition fa speaks of particular objects, the general proposition of *all* objects.

11.7.16.

Page 75

The particular object is a very remarkable phenomenon.

Instead of "all objects" we might say: All *particular objects*.

If all particular objects are given, "all objects" are given.

In short with the particular objects all objects are given. [Cf. 5.524.]

If there are objects, then that gives us "all objects" too. [Cf. 5.524.]

That is why it must be possible to construct the unity of the elementary propositions and of the general propositions.

For if the elementary propositions are given, that gives us *all* elementary propositions, too, and that gives us the general proposition.--And with that has not the unity been constructed? [Cf. 5.524.]

13.7.16.

One keeps on feeling that even in the elementary proposition mention is made of all objects.

$(\exists x)\phi x.x = a$

If two operations are given which cannot be reduced to *one*, then it must at least be possible to set up a general form of their combination.

$\phi x, \psi y | \chi z, (\exists x), (x).$

As obviously it can easily be explained how propositions can be formed by means of these operations and how propositions are not to be formed, this must also be capable *somehow* of exact expression.

14.7.16.

And this expression must already be given in the general form of the sign of an operation.

And mustn't this be the only legitimate expression of the application of an operation? Obviously it must!

For if the form of operation can be expressed at all, then it must be expressed in such a way that it *can* only be applied correctly.

Man cannot make himself happy without more ado.

Whoever lives in the present lives without fear and hope.

21.7.16.

What really is the situation of the human will? I will call "will" first and foremost the bearer of good and evil.

Let us imagine a man who could use none of his limbs and hence could, in the ordinary sense, not exercise his *will*. He could, however, think and *want* and communicate his thoughts to someone else. Could

therefore do good or evil through the other man. Then it is clear that ethics would have validity for him, too, and that he in the *ethical sense* is the bearer of a *will*.

Now is there any difference in principle between this will and that which sets the human body in motion?

Or is the mistake here this: even *wanting* (thinking) is an activity of the will? (And in this sense, indeed, a man *without* will would not be alive.)

But can we conceive a being that isn't capable of Will at all, but only of Idea (of seeing for example)? In some sense this seems impossible. But if it were possible then there could also be a world without ethics.

24.7.16.

Page 77

The World and Life are one. [5.621.]

Page 77

Physiological life is of course not "Life". And neither is psychological life. Life is the world.

Page 77

Ethics does not treat of the world. Ethics must be a condition of the world, like logic.

Page 77

Ethics and aesthetics are one. [See 6.421.]

29.7.16.

Page 77

For it is a fact of logic that wanting does not stand in any logical connexion with its own fulfilment. And it is also clear that the world of the happy is a *different* world from the world of the unhappy. [Cf. 6.43.]

Page 77

Is seeing an activity?

Page 77

Is it possible to will good, to will evil, and not to will?

Page 77

Or is only he happy who does *not* will?

Page 77

"To love one's neighbour" would mean to will!

Page 77

But can one want and yet not be unhappy if the want does not attain fulfilment? (And this possibility always exists.)

Page 77

Is it, according to common conceptions, good to want *nothing* for one's neighbour, neither good nor evil?

Page 77

And yet in a certain sense it seems that not wanting is the only good.

Page Break 78

Page 78

Here I am still making crude mistakes! No doubt of that!

Page 78

It is generally assumed that it is evil to want someone else to be unfortunate. Can this be correct? Can it be worse than to want him to be fortunate?

Page 78

Here everything seems to turn, so to speak, on *how* one wants.

Page 78

It seems one can't say anything more than: Live happily!

Page 78

The world of the happy is a different world from that of the unhappy. [See 6.43.]

Page 78

The world of the happy is a *happy world*.

Page 78

Then can there be a world that is neither happy nor unhappy?

30.7.16.

Page 78

When a general ethical law of the form "Thou shalt..." is set up, the first thought is: Suppose I do not do it?

Page 78

But it is clear that ethics has nothing to do with punishment and reward. So this question about the consequences of an action must be unimportant. At least these consequences cannot be events. For there must be something right about that question after all. There must be a *kind* of ethical reward and of ethical punishment but these must be involved in the action itself.

Page 78

And it is also clear that the reward must be something pleasant, the punishment something unpleasant.

Page 78

[6.422.]

Page 78

I keep on coming back to this! simply the happy life is good, the unhappy bad. And if I *now* ask myself: But why should I live *happily*, then this of itself seems to me to be a tautological question; the happy life seems to be justified, of itself, it seems that it *is* the only right life.

Page 78

But this is really in some sense deeply mysterious! *It is clear* that ethics *cannot* be expressed! [Cf. 6.421.]

Page 78

But we could say: The happy life seems to be in some sense more *harmonious* than the unhappy. But in what sense??

Page 78

What is the objective mark of the happy, harmonious life? Here it is again clear that there cannot be any such mark, that can be *described*.

Page 78

This mark cannot be a physical one but only a metaphysical one, a transcendental one.

Page Break 79

Page 79

Ethics is transcendental. [See 6.421.]

1.8.16.

Page 79

How things stand, is God.

Page 79

God is, how things stand.

Page 79

Only from the consciousness of the *uniqueness of my life* arises religion--science--and art.

2.8.16.

Page 79

And this consciousness is life itself.

Page 79

Can there be any ethics if there is no living being but myself?

Page 79

If ethics is supposed to be something fundamental, there can.

Page 79

If I am right, then it is not sufficient for the ethical judgment that a world is given.

Page 79

Then the world in itself is neither good nor evil.

Page 79

For it must be all one, as far as concerns the existence of ethics, whether there is living matter in the world or not. And it is clear that a world in which there is only dead matter is in itself neither good nor evil, so even the world of living things can in itself be neither good nor evil.

Page 79

Good and evil only enter through the *subject*. And the subject is not part of the world, but a boundary of the world. [Cf. 5.632.]

Page 79

It would be possible to say (à la Schopenhauer): It is not the world of Idea that is either good or evil; but the willing subject.

Page 79

I am conscious of the complete unclarity of all these sentences.

Page 79

Going by the above, then, the willing subject would have to be happy or unhappy, and happiness and unhappiness could not be part of the world.

Page 79

As the subject is not a part of the world but a presupposition of its existence, so good and evil which are predicates of the subject, are not properties in the world.

Page 79

Here the nature of the subject is completely veiled.

Page 79

My work has extended from the foundations of logic to the nature of the world.

Page Break 80

4.8.16.

Page 80

Isn't the thinking subject in the last resort mere superstition?

Page 80

Where in the world is a metaphysical subject to be found? [See 5.633.]

Page 80

You say that it is just as it is for the eye and the visual field. But you do *not* actually see the eye. [See 5.633.]

Page 80

And I think that nothing in the visual field would enable one to infer that it is seen from an eye. [Cf. 5.633.]

5.8.16.

Page 80

The thinking subject is surely mere illusion. But the willing subject exists. [Cf. 5.631.]

Page 80

If the will did not exist, neither would there be that centre of the world, which we call the I, and which is the bearer of ethics.

Page 80

What is good and evil is essentially the I, not the world.

Page 80

The I, the I is what is deeply mysterious!

7.8.16.

Page 80

The I is not an object.

11.8.16.

Page 80

I objectively confront every object. But not the I.

Page 80

So there really is a way in which there can and must be mention of the I in a *non-psychological sense* in philosophy. [Cf. 5.641.]

12.8.16.

Page 80

The I makes its appearance in philosophy through the world's being *my* world. [See 5.641.]

Page 80

The visual field has not, e.g., a form like this:

Page 80

[5.6331.]

Page 80

This is connected with the fact that none of our experience is *a priori*. [See 5.634.]

Page 80

All that we see could also be otherwise.

Page 80

All that we can describe at all could also be otherwise. [See 5.634.]

Page Break 81

13.8.16.

Page 81

Suppose that man could not exercise his will, but had to suffer all the misery of this world, then what could

make him happy?

Page 81

How can man be happy at all, since he cannot ward off the misery of this world?

Page 81

Through the life of knowledge.

Page 81

The good conscience is the happiness that the life of knowledge preserves.

Page 81

The life of knowledge is the life that is happy in spite of the misery of the world.

Page 81

The only life that is happy is the life that can renounce the amenities of the world.

Page 81

To it the amenities of the world are so many graces of fate.

16.8.16.

Page 81

A point cannot be red and green at the same time: at first sight there seems no need for this to be a logical impossibility. But the very language of physics reduces it to a kinetic impossibility. We see that there is a difference of structure between red and green.

Page 81

And then physics arranges them in a series. And then we see how here the true structure of the objects is brought to light.

Page 81

The fact that a particle cannot be in two places at the same time does look more like a logical impossibility.

Page 81

If we ask why, for example, then straight away comes the thought: Well, we should call particles that were in two places different, and this in its turn all seems to follow from the structure of space and of particles.

Page 81

[Cf. 6.3751.]

17.8.16.

Page 81

An operation is the transition from one term to the next one in a series of forms.

Page 81

The operation and the series of forms are equivalents.

29.8.16.

Page 81

The question is whether the usual small number of fundamental operations is adequate for the construction of all possible operations.

Page 81

It looks as if it must be so.

Page Break 82

Page 82

We can also ask whether those fundamental operations enable us to pass from any expression to any related ones.

2.9.16.

Page 82

Here we can see that solipsism coincides with pure realism, if it is strictly thought out.

Page 82

The I of solipsism shrinks to an extensionless point and what remains is the reality coordinate with it.

Page 82

[5.64.]

Page 82

What has history to do with me? Mine is the first and only world!

Page 82

I want to report how *I* found the world.

Page 82

What others in the world have told me about the world is a very small and incidental part of my experience

of the world.

Page 82

I have to judge the world, to measure things.

Page 82

The philosophical *I* is not the human being, not the human body or the human soul with the psychological properties, but the metaphysical subject, the boundary (not a part) of the world. The human body, however, my body in particular, is a part of the world among others, among beasts, plants, stones etc., etc. [Cf. 5.641.]

Page 82

Whoever realizes this will not want to procure a pre-eminent place for his own body or for the human body.

Page 82

He will regard humans and beasts quite naïvely as objects which are similar and which belong together.

11.9.16.

Page 82

The way in which language signifies is mirrored in its use.

Page 82

That the colours are not properties is shewn by the analysis of physics, by the internal relations in which physics displays the colours.

Page 82

Apply this to sounds too.

12.9.16.

Page 82

Now it is becoming clear why *I* thought that thinking and language were the same. For thinking is a kind of language. For a thought too is, of course, a logical picture of the proposition, and therefore it just is a kind of proposition.

Page Break 83

19.9.16.

Page 83

Mankind has always looked for a science in which *simplex sigillum veri* holds. [Cf. 5.4541.]

Page 83

There cannot be an orderly or a disorderly world, so that one could say that our world is orderly. In every possible world there is an order even if it is a complicated one, just as in space too there are not orderly and disorderly distributions of points, but every distribution of points is orderly.

Page 83

(This remark is only material for a thought.)

Page 83

Art is a kind of expression.

Page 83

Good art is complete expression.

7.10.16

Page 83

The work of art is the object seen *sub specie aeternitatis*; and the good life is the world seen *sub specie aeternitatis*. This is the connexion between art and ethics.

Page 83

The usual way of looking at things sees objects as it were from the midst of them, the view *sub specie aeternitatis* from outside.

Page 83

In such a way that they have the whole world as background.

Page 83

Is this it perhaps--in this view the object is seen *together with* space and time instead of *in* space and time?

Page 83

Each thing modifies the whole logical world, the whole of logical space, so to speak.

Page 83

(The thought forces itself upon one): The thing seen *sub specie aeternitatis* is the thing seen together with the whole logical space.

8.10.16.

Page 83

As a thing among things, each thing is equally insignificant; as a world each one equally significant.

Page 83

If I have been contemplating the stove, and then am told: but now all you know is the stove, my result does indeed seem trivial. For this represents the matter as if I had studied the stove as one among the many things in the world. But if I was contemplating the stove *it* was my world, and everything else colourless by contrast with it.

Page 83

(Something good about the whole, but bad in details.)

Page 83

For it is equally possible to take the bare present image as the worthless momentary picture in the whole temporal world, and as the true world among shadows.

Page Break 84

9.10.16.

Page 84

But now at last the connexion of ethics with the world has to be made clear.

12.10.16.

Page 84

A stone, the body of a beast, the body of a man, my body, all stand on the same level.

Page 84

That is why what happens, whether it comes from a stone or from my body is neither good nor bad.

Page 84

"Time has only one direction" must be a piece of nonsense.

Page 84

Having only one direction is a logical property of time.

Page 84

For if one were to ask someone how he imagines having only one direction he would say: Time would not be confined to one direction if an event could be repeated.

Page 84

But the impossibility of an event's being repeated, like that of a body's being in two places at once, is involved in the logical nature of the event.

Page 84

It is true: Man *is* the microcosm:

Page 84

I am my world. [*Cf.* 5.63.]

15.10.16.

Page 84

What cannot be imagined cannot even be talked about. [*Cf.* 5.61.]

Page 84

Things acquire "significance" only through their relation to my will.

Page 84

For "Everything is what it is and not another thing".

Page 84

One conception: As I can infer my spirit (character, will) from my physiognomy, so I can infer the spirit (will) of each thing from *its* physiognomy.

Page 84

But can I *infer* my spirit from my physiognomy?

Page 84

Isn't this relationship purely empirical?

Page 84

Does my body really express anything?

Page 84

Is it itself an internal expression of something?

Page 84

Is, e.g., an angry face angry in itself or merely because it is empirically connected with bad temper?

Page 84

But it is clear that the causal nexus is not a nexus at all. [*Cf.* 5.136.]

Now is it true (following the psycho-physical conception) that my character is expressed only in the build of *my* body or brain and not equally in the build of the whole of the rest of the world?

This contains a salient point.

This parallelism, then, really exists between my spirit, i.e. spirit, and the world.

Only remember that the spirit of the snake, of the lion, is *your* spirit. For it is only from yourself that you are acquainted with spirit at all.

Now of course the question is why I have given a snake just this spirit.

And the answer to this can only lie in the psycho-physical parallelism: If I were to look like the snake and to do what it does then I should be such-and-such.

The same with the elephant, with the fly, with the wasp.

But the question arises whether even here, my body is not on the same level with that of the wasp and of the snake (and surely it is so), so that I have neither inferred from that of the wasp to mine nor from mine to that of the wasp.

Is this the solution of the puzzle why men have always believed that there was *one* spirit common to the whole world?

And in that case it would, of course, also be common to lifeless things too.

This is the way I have travelled: Idealism singles men out from the world as unique, solipsism singles me alone out, and at last I see that I too belong with the rest of the world, and so on the one side *nothing* is left over, and on the other side, as unique, *the world*. In this way idealism leads to realism if it is strictly thought out. [Cf. 5.64.]

17.10.16.

And in this sense I can also speak of a will that is common to the whole world.

But this will is in a higher sense *my* will.

As my idea is the world, in the same way my will is the world-will.

20.10.16.

It is clear that my visual space is constituted differently in length from breadth.

The situation is not simply that I everywhere notice where I see anything, but I also always find myself at a particular point of my visual space, so my visual space has as it were a shape.

In spite of this, however, it is true that I do not see the subject.

It is true that the knowing subject is not in the world, that there is no knowing subject. [Cf. 5.631.]

At any rate I can imagine carrying out the act of will for raising my arm, but that my arm does not move. (E.g., a sinew is torn.) True, but, it will be said, the sinew surely moves and that just shews that the act of will related to the sinew and not to the arm. But let us go farther and suppose that even the sinew did not move, and so on. We should then arrive at the position that the act of will does not relate to a body at all, and so that in the ordinary sense of the word there is no such thing as the act of the will.

Page 86

Aesthetically, the miracle is that the world exists. That there is what there is.

Page 86

Is it the essence of the artistic way of looking at things, that it looks at the world with a happy eye?

Page 86

Life is grave, art is gay. †1

21.10.16.

Page 86

For there is certainly something in the conception that the end of art is the beautiful.

Page 86

And the beautiful *is* what makes happy.

29.10.16.

Page 86

Could it not be said that generality is no more co-ordinated with the complex than is fact with thing?

Page 86

Both kinds of operation sign must or can occur in the proposition side by side.

4.11.16.

Page 86

Is the will an attitude towards the world?

Page 86

The will seems always to have to relate to an idea. We cannot imagine, e.g., having carried out an act of will without having detected that we have carried it out.

Page Break 87

Page 87

Otherwise there might arise such a question as whether it had yet been *completely* carried out.

Page 87

It is clear, so to speak, that we need a foothold for the will in the world.

Page 87

The will is an attitude of the subject to the world.

Page 87

The subject is the willing subject.

Page 87

Have the feelings by which I ascertain that an act of the will takes place any particular characteristic which distinguishes them from other ideas?

Page 87

It seems not!

Page 87

In that case, however, I might conceivably get the idea that, e.g., this chair was directly obeying my will.

Page 87

Is that possible?

Page 87

In drawing the square in the mirror one notices that one is only able to manage it if one prescind completely from the visual datum and relies only on muscular feeling. So here after all there are two quite different acts of the will in question. The one relates to the visual part of the world, the other to the muscular-feeling part.

Page 87

Have we anything more than empirical evidence that the movement of the same part of the body is in question in both cases?

Page 87

Then is the situation that I merely accompany my actions with my will?

Page 87

But in that case how can I predict--as in some sense I surely can--that I shall raise my arm in five minutes' time? That I shall will this?

Page 87

This is clear: it is impossible to will without already performing the act of the will.

Page 87

The act of the will is not the cause of the action but is the action itself.

Page 87

One cannot will without acting.

Page 87

If the will has to have an object in the world, the object can be the intended action itself.

Page 87

And the will does have to have an object.

Page Break 88

Page 88

Otherwise we should have no foothold and could not know what we willed.

Page 88

And could not will different things.

Page 88

Does not the willed movement of the body happen just like any unwilled movement in the world, but that it is accompanied by the will?

Page 88

Yet it is not accompanied just by a *wish*! But by will.

Page 88

We feel, so to speak, responsible for the movement.

Page 88

My will fastens on to the world somewhere, and does not fasten on to other things.

Page 88

Wishing is not acting. But willing is acting.

Page 88

(My wish relates, e.g., to the movement of the chair, my will to a muscular feeling.)

Page 88

The fact that I will an action consists in my performing the action, not in my doing something else which causes the action.

Page 88

When I move something I move.

Page 88

When I perform an action I am in action.

Page 88

But: I cannot will everything.--

Page 88

But what does it mean to say: "I cannot will *this*"?

Page 88

Can I try to will something?

Page 88

For the consideration of willing makes it look as if one part of the world were closer to me than another (which would be intolerable).

Page 88

But, of course, it is undeniable that in a popular sense there are things that I do, and other things not done by me.

Page 88

In this way then the will would not confront the world as its equivalent, which must be impossible.

Page 88

The wish precedes the event, the will accompanies it.

Page 88

Suppose that a process were to accompany my wish. Should I have willed the process?

Page 88

Would not this accompanying appear accidental in contrast to the compelled accompanying of the will?

Page 89

Is belief a kind of experience?

Page 89

Is thought a kind of experience?

Page 89

All experience is world and does not need the subject.

Page 89

The act of will is not an experience.

19.11.16.

Page 89

What kind of reason is there for the assumption of a willing subject?

Page 89

Is not *my world* adequate for individuation?

21.11.16.

Page 89

The fact that it is possible to erect the general form of proposition means nothing but: every possible form of proposition must be FORESEEABLE.

Page 89

And *that* means: We can never come upon a form of proposition of which we could say: it could not have been foreseen that there was such a thing as this.

Page 89

For that would mean that we had had a new experience, and that it took that to make this form of proposition possible.

Page 89

Thus it must be possible to erect the general form of proposition, because the possible forms of proposition must be *a priori*. Because the possible forms of proposition are *a priori*, the general form of proposition exists.

Page 89

In this connexion it does not matter at all whether the given fundamental operations, through which all propositions are supposed to arise, change the logical level of the propositions, or whether they remain on the same logical level.

Page 89

If a sentence were ever going to be constructable it would already be constructable.

Page 89

We now need a clarification of the concept of the atomic function and the concept "and so on".

Page 89

The concept "and so on", symbolized by "...." is one of the most important of all and like all the others infinitely fundamental.

Page 89

For it alone justifies us in constructing logic and mathematics "so on" from the fundamental laws and primitive signs.

Page 89

The "and so on" makes its appearance right away at the very beginning of the old logic when it is said that after the primitive signs have been given we can develop one sign after another "so on".

Page 90

Without this concept we should be stuck at the primitive signs and could not go "on".

Page 90

The concept "and so on" and the concept of the operation are equivalent. [Cf. 5.2523.]

Page 90

After the operation sign there follows the sign "...." which signifies that the result of the operation can in its turn be taken as the base of the operation; "and so on".

22.11.16.

Page 90

The concept of the operation is quite generally that according to which signs can be constructed according to

a rule.

23.11.16.

Page 90

What does the possibility of the operation depend on?

Page 90

On the general concept of structural similarity.

Page 90

As I conceive, e.g., the elementary propositions, there must be something common to them; otherwise I could not speak of them all collectively as the "elementary propositions" at all.

Page 90

In that case, however, they must also be capable of being developed from one another as the results of operations.

Page 90

For if there really is something common to two elementary propositions which is not common to an elementary proposition and a complex one, then this common thing must be capable of being given general expression in some way.

24.11.16.

Page 90

When the general characteristic of an operation is known it will also be clear of what elementary component parts an *operation* always consists.

Page 90

When the general form of operations is found we have also found the general form of the occurrence of the concept "and so on".

26.11.16.

Page 90

All operations are composed of the fundamental operations.

28.11.16.

Page 90

Either a fact is contained in another one, or it is independent of it.

2.12.16.

Page 90

The similarity of the generality notation and the argument appears if we write $(\forall x)\phi x$ instead of ϕa . [Cf. 5.523.]

Page Break 91

Page 91

We could introduce the arguments also in such a way that they only occurred on one side of the sign of identity, i.e. always on the analogy of " $(\exists x).\phi x.x = a$ " instead of " ϕa ".

Page 91

The correct method in philosophy would really be to say nothing except what can be said, i.e. what belongs to natural science, i.e. something that has nothing to do with philosophy, and then whenever someone else tried to say something metaphysical to shew him that he had not given any reference to certain signs in his sentences. [See 6.53.]

Page 91

This method would be unsatisfying for the other person (he would not have the feeling that we were teaching him philosophy) but it would be the only correct one. [See 6.53.]

7.1.17.

Page 91

In the sense in which there is a hierarchy of propositions there is, of course, also a hierarchy of truths and of negations, etc.

Page 91

But in the sense in which there are, in the most general sense, such things as propositions, there is only one truth and one negation.

Page 91

The latter sense is obtained from the former by conceiving the proposition in general as the result of the single operation which produces all propositions from the first level. Etc.

Page 91

The lowest level and the operation can stand for the whole hierarchy.

8.1.17.

Page 91

It is clear that the logical product of two elementary propositions can never be a tautology. [*Cf.* 6.3751.]

Page 91

If the logical product of two propositions is a contradiction, and the propositions appear to be elementary propositions, we can see that in this case the appearance is deceptive. (E.g.: A is red and A is green.)

10.1.17.

Page 91

If suicide is allowed then everything is allowed.

Page 91

If anything is not allowed then suicide is not allowed.

Page 91

This throws a light on the nature of ethics, for suicide is, so to speak, the elementary sin.

Page 91

And when one investigates it it is like investigating mercury vapour in order to comprehend the nature of vapours.

Page 91

Or is even suicide in itself neither good nor evil?

Page Break 92

Page Break 93

APPENDIX I
NOTES ON LOGIC
 by
 Ludwig Wittgenstein
 1913

SUMMARY

Page 93

ONE reason for thinking the old notation wrong is that it is very unlikely that from every proposition p an infinite number of other propositions not-not-p, not-not-not-not-p, etc., should follow. [*Cf.* 5.43.]

Page 93

If only those signs which contain proper names were complex then propositions containing nothing but apparent variables would be simple. Then what about their denials?

Page 93

The verb of a proposition cannot be "is true" or "is false", but whatever is true or false must already contain the verb. [*See* 4.063.]

Page 93

Deductions only proceed according to the laws of deduction but these laws cannot justify the deduction.

Page 93

One reason for supposing that not all propositions which have more than one argument are relational propositions is that if they were, the relations of judgment and inference would have to hold between an arbitrary number of things.

Page 93

Every proposition which seems to be about a complex can be analysed into a proposition about its constituents and about the proposition which describes the complex perfectly; i.e., that proposition which is equivalent to saying the complex exists. [*Cf.* 2.0201.]

Page 93

The idea that propositions are names of complexes suggests that whatever is not a proper name is a sign for a relation. Because spatial complexes†1 consist of Things and Relations only and the idea of a complex is taken from space.

Page 93

In a proposition convert all its indefinables into variables; there then remains a class of propositions which is

not all propositions but a type [Cf. 3.315.]

Page 93

There are thus two ways in which signs are similar. The names "Socrates" and "Plato" are similar: they are both names. But whatever they have in common must not be introduced before "Socrates" and "Plato" are introduced. The same applies to a subject-predicate form etc.. Therefore, thing, proposition, subject-predicate forth, etc., are not indefinables, i.e., types are not indefinables.

Page Break 94

Page 94

When we say A judges that etc., then we have to mention a whole proposition which A judges. It will not do either to mention only its constituents, or its constituents and form, but not in the proper order. This shows that a proposition itself must occur in the statement that it is judged; however, for instance, "not-p" may be explained, the question what is negated must have a meaning.

Page 94

To understand a proposition p it is not enough to know that p implies "' p ' is true", but we must also know that $\sim p$ implies " p is false". This shows the bi-polarity of the proposition.

Page 94

To every molecular function a $WF\uparrow 1$ scheme corresponds. Therefore we may use the WF scheme itself instead of the function. Now what the WF scheme does is, it correlates the letters W and F with each proposition. These two letters are the poles of atomic propositions. Then the scheme correlates another W and F to these poles. In this notation all that matters is the correlation of the outside poles to the poles of the atomic propositions. Therefore not-not- p is the same symbol as p . And therefore we shall never get two symbols for the same molecular function.

Page 94

The meaning of a proposition is the fact which actually corresponds to it.

Page 94

As the ab functions of atomic propositions are bi-polar propositions again we can perform ab operations on them. We shall, by doing so, correlate two new outside poles via the old outside poles to the poles of the atomic propositions.

Page 94

The symbolising fact in $a-p-b$ is that, $SA Y\uparrow 2$ a is on the left of p and b on the right of p ; then the correlation of new poles is to be transitive, so that for instance if a new pole a in whatever way i.e. via whatever poles is correlated to the inside a , the symbol is not changed thereby. It is therefore possible to construct all possible ab functions by performing one ab operation repeatedly, and we can therefore talk of all ab functions as of all those functions which can be obtained by performing this ab operation repeatedly.

Page 94

Naming is like pointing. A function is like a line dividing points of a plane into right and left ones; then " p or not- p " has no meaning because it does not divide the plane.

Page 94

But though a particular proposition " p or not- p " has no meaning, a general proposition "for all p 's, p or not- p " has a meaning because this

Page Break 95

does not contain the nonsensical function " p or not- p " but the function " p or not- q " just as "for all x 's xRx " contains the function " xRy ".

Page 95

A proposition is a standard to which facts behave, $\uparrow 1$ with names it is otherwise; it is thus bi-polarity and sense comes in; just as one arrow behaves $\uparrow 2$ to another arrow by being in the same sense or the opposite, so a fact behaves to a proposition.

Page 95

The form of a proposition has meaning in the following way. Consider a symbol " xRy ". To symbols of this form correspond couples of things whose names are respectively " x " and " y ". The things xy stand to one another in all sorts of relations, amongst others some stand in the relation R , and some not; just as I single out a particular thing by a particular name I single out all behaviours of the points x and y with respect to the relation R . I say that if an x stands in the relation R to a y the sign " xRy " is to be called true to the fact and otherwise false. This is a definition of

sense.

Page 95

In my theory p has the same meaning as $\neg p$ but opposite sense. The meaning is the fact. The proper theory of judgment must make it impossible to judge nonsense. [Cf. 4.0621 and 5.5422.]

Page 95

It is not strictly true to say that we understand a proposition p if we know that p is equivalent to " p is true" for this would be the case if accidentally both were true or false. What is wanted is the formal equivalence with respect to the forms of the proposition, *i.e.*, all the general indefinables involved. The *sense of an ab function of a proposition* is a function of *its* sense. There are only unasserted propositions. Assertion is merely psychological. In *not- p* , p is exactly the same as if it stands alone; this point is absolutely fundamental. Among the facts which make " p or q " true there are also facts which make " p and q " true; if propositions have only meaning, we ought, in such a case, to say that these two propositions are identical, but in fact, their sense is different for we have introduced sense by talking of all p 's and all q 's. Consequently the molecular propositions will only be used in cases where their *ab* function stands under a generality sign or enters into another function such as "I believe that, etc.", because then the sense enters. [Cf. 5.2341.]

Page 95

In " a judges p " p cannot be replaced by a proper name. This appears if we substitute " a judges that p is true and $\neg p$ is false". The proposition " a judges p " consists of the proper name a , the proposition p with its 2 poles, and a being related to both of these poles in a certain way. This is obviously not a relation in the ordinary sense.

Page 95

The *ab* notation makes it clear that *not* and *or* are dependent on one another and we can therefore not use them as simultaneous indefinables.

Page Break 96

Same objections in the case of apparent variables to old indefinables, as in the case of molecular functions. The application of the *ab* notation to apparent variable propositions becomes clear if we consider that, for instance, the proposition " $\forall x, \phi x$ " is to be true when ϕx is true for all x 's and false when ϕx is false for some x 's. We see that *some* and *all* occur simultaneously in the proper apparent variable notation.

Page 96

The notation is

for $(x)\phi x$: $a-(x)-a\phi xb-(\exists x)-b$ and
for $(\exists x)\phi x$: $a-(\exists x)-a\phi xb-(x)-b$

Page 96

Old definitions now become tautologous.

Page 96

In " aRb " it is not the complex that symbolises but the fact that the symbol " a " stands in a certain relation to the symbol " b ". Thus facts are symbolised by facts, or more correctly: that a certain thing is the case in the symbol says that a certain thing is the case in the world. [Cf. 3.1432.]

Page 96

Judgment, question and command are all on the same level. What interests logic in them is only the unasserted proposition. Facts cannot be named.

Page 96

A proposition cannot occur in itself. This is the fundamental truth of the theory of types. [Cf. 3.332.]

Page 96

Every proposition that says something indefinable about one thing is a subject-predicate proposition, and so on.

Page 96

Therefore we can recognize a subject-predicate proposition if we know it contains only one name and one form, etc. This gives the construction of types. Hence the type of a proposition can be recognized by its symbol alone.

Page 96

What is essential in a correct apparent-variable notation is this: (1) it must mention a type of propositions; (2) it must show which components of a proposition of this type are constants.

Page 96

[Components are forms and constituents.]

Take $(\phi).\phi!x$. Then if we describe the *kind* of symbols, for which " $\phi!$ " stands and which, by the above, is enough to determine the type, then automatically " $(\phi).\phi!x$ " cannot be fitted by this description, because it *CONTAINS* " $\phi!x$ " and the description is to describe *ALL* that symbolises in symbols of the $\phi!$ kind. If the description is *thus* complete vicious circles can just as little occur as for instance $(\phi).(x)\phi$ (where $(x)\phi$ is a subject-predicate proposition).

FIRST MS

Indefinables are of two sorts: names, and forms. Propositions cannot consist of names alone; they cannot be classes of names. A name can not only occur in two different propositions, but can occur in the same way in both.

Propositions [which are symbols having reference to facts] are themselves facts: that this inkpot is on this table may express that I sit in this chair. [Cf. 2.141 and 3.14.]

It can never express the common characteristic of two objects that we designate them by the same name but by two different ways of designation, for, since names are arbitrary, we might also choose different names, and where then would be the common element in the designations? Nevertheless one is always tempted, in a difficulty, to take refuge in different ways of designation. [Cf. 3.322.]

Frege said "propositions are names"; Russell said "propositions correspond to complexes". Both are false; and especially false is the statement "propositions are names of complexes". [Cf. 3.143.]

It is easy to suppose that only such symbols are complex as contain names of objects, and that accordingly " $(\exists x, \phi).\phi x$ " or " $(\exists x, y).xRy$ " must be simple. It is then natural to call the first of these the name of a form, the second the name of a relation. But in that case what is the meaning of (e.g.) " $\sim(\exists x, y)xRy$ "? Can we put "not" before a name?

The reason why " \sim Socrates" means nothing is that " $\sim x$ " does not express a property of x .

There are positive and negative facts: if the proposition "this rose is not red" is true, then what it signifies is negative. But the occurrence of the word "not" does not indicate this unless we know that the signification of the proposition "this rose is red" (when it is true) is positive. It is only from both, the negation and the negated proposition, that we can conclude to a characteristic of the significance of the whole proposition. (We are not here speaking of negations of *general* propositions i.e. of such as contain apparent variables. Negative facts only justify the negations of atomic propositions.)

Positive and *negative* facts there are, but not *true* and *false* facts.

If we overlook the fact that propositions have a *sense* which is independent of their truth or falsehood, it easily seems as if true and false were two equally justified relations between the sign and what is signified. (We might then say e.g. that " q " *signifies* in the true way what "not- q " *signifies* in the false way.) But are not true and false in fact equally justified? Could we not express ourselves by means of false propositions just as well as hitherto with true ones, so long as we know that they are meant falsely? No! For a proposition is then true when it is as we assert in this proposition; and accordingly if by " q " we mean "not- q ", and it is as we mean to assert, then in the new interpretation " q " is actually true and *not* false. But it is important that we *can* mean the same by " q " as by "not- q ", for it shows that neither to the symbol "not" nor to the manner of its combination with " q " does a

characteristic of the denotation of " q " correspond. [Cf. 4.061, 4.062, 4.0621.]

SECOND MS

We must be able to understand propositions which we have never heard before. But every proposition is a new symbol. Hence we must have *general* indefinable symbols; these are unavoidable if propositions are not all indefinable. [Cf. 4.02, 4.021, 4.027.]

Page 98

Whatever corresponds in reality to compound propositions must not be more than what corresponds to their several atomic propositions.

Page 98

Not only must logic not deal with [particular] things, but just as little with relations and predicates.

Page 98

There are no propositions containing real variables.

Page 98

What corresponds in reality to a proposition depends upon whether it is true or false. But we must be able to understand a proposition without knowing if it is true or false.

Page 98

What we know when we understand a proposition is this: We know what is the case if the proposition is true, and what is the case if it is false. But we do not know (necessarily) whether it is true or false. [Cf. 4.024.]

Page 98

Propositions are not names.

Page 98

We can never distinguish one logical type from another by attributing a property to members of the one which we deny to members of the other.

Page 98

Symbols are not what they seem to be. In " aRb ", " R " looks like a substantive, but is not one. What symbolizes in " aRb " is that R occurs between a and b . Hence " R " is *not* the indefinable in " aRb ". Similarly in " ϕx ", " ϕ " looks like a substantive but is not one; in " $\sim p$ ", " \sim " looks like " ϕ " but is not like it. This is the first thing that indicates that there *may* not be logical constants. A reason against them is the generality of logic: logic cannot treat a special set of things. [Cf. 3.1423.]

Page 98

Molecular propositions contain nothing beyond what is contained in their atoms; they add no material information above that contained in their atoms.

Page 98

All that is essential about molecular functions is their T-F schema (i.e. the statement of the cases when they are true and the cases when they are false).

Page 98

Alternative indefinability shows that the indefinables have not been reached.

Page 98

Every proposition is essentially true-false: to understand it, we must know both what must be the case if it is true, and what must be the case if it is false. Thus a proposition has two *poles*, corresponding to the

Page Break 99

case of its truth and the case of its falsehood. We call this the *sense* of a proposition.

Page 99

In regard to notation, it is important to note that not every feature of a symbol symbolizes. In two molecular functions which have the same T-F schema, what symbolizes must be the same. In "not-not- p ", "not- p " does not occur; for "not-not- p " is the same as " p ", and therefore, if "not- p " occurred in "not-not- p ", it would occur in " p ".

Page 99

Logical indefinables cannot be predicates or relations, because propositions, owing to sense, cannot have predicates or relations. Nor are "not" and "or", like judgment, *analogous* to predicates or relations, because they do not introduce anything new.

Page 99

Propositions are always complex even if they contain no names.

Page 99

A proposition must be understood when *all* its indefinables are understood. The indefinables in " aRb " are introduced as follows:

Page 99

" a " is indefinable;

Page 99

" b " is indefinable;

Page 99

Whatever " x " and " y " may mean, " xRy " says something indefinable about their meaning. [Cf. 4.024.]

A complex symbol must never be introduced as a single indefinable. [Thus e.g. no proposition is indefinable.] For if one of its parts occurs also in another connection, it must there be re-introduced. And would it then mean the same?

The ways by which we introduce our indefinables must permit us to construct all propositions that have sense from these indefinables *alone*. It is easy to introduce "all" and "some" in a way that will make the construction of (say) "(x,y).xRy" possible from "all" and "xRy" *as introduced before*.

THIRD MS

An analogy for the theory of truth: Consider a black patch on white paper; then we can describe the form of the patch by mentioning, for each point of the surface, whether it is white or black. To the fact that a point is black corresponds a positive fact, to the fact that a point is white (not black) corresponds a negative fact. If I designate a point of the surface (one of Frege's "truth-values"), this is as if I set up an assumption to be decided upon. But in order to be able to say of a point that it is black or that it is white, I must first know when a point is to be called black and when it is to be called white. In order to be able to say that "p" is true (or false), I must first have determined under what circumstances I call a proposition true, and thereby I determine the *sense* of a proposition. The point in which the analogy fails is this: I can indicate a point of the paper which is white and black, † I but to a

proposition without sense nothing corresponds, for it does not designate a thing (truth-value), whose properties might be called "false" or "true"; the verb of a proposition is not "is true" or "is false", as Frege believes, but what is true must already contain the verb. [Cf. 5.132.]

The comparison of language and reality is like that of retinal image and visual image: to the blind spot nothing in the visual image seems to correspond, and thereby the boundaries of the blind spot determine the visual image--as true negations of atomic propositions determine reality.

Logical inferences can, it is true, be made in accordance with Frege's or Russell's laws of deduction, but this cannot justify the inference; and therefore they are not primitive propositions of logic. If p follows from q , it can also be inferred from q , and the "manner of deduction" is indifferent.

Those symbols which are called propositions in which "variables occur" are in reality not propositions at all, but only schemes of propositions, which only become propositions when we replace the variables by constants. There is no proposition which is expressed by " $x = x$ ", for " x " has no signification; but there is a proposition " $(x).x = x$ " and propositions such as "Socrates = Socrates" etc.

In books on logic, no variables ought to occur, but only the general propositions which justify the use of variables. It follows that the so-called definitions of logic are not definitions, but only schemes of definitions, and instead of these we ought to put general propositions; and similarly the so-called primitive ideas (*Urzeichen*) of logic are not primitive ideas, but the schemes of them. The mistaken idea that there are things called facts or complexes and relations easily leads to the opinion that there must be a relation of questioning to the facts, and then the question arises whether a relation can hold between an arbitrary number of things, since a fact can follow from arbitrary cases. It is a fact that the proposition which e.g. expresses that q follows from p and $p \supset q$ is this: $p.p \supset q.$
 $\supset p.q.q.$

At a pinch, one is tempted to interpret "not- p " as "everything else, only not p ". That from a single fact p an infinity of others, not-not- p etc., follow, is hardly credible. Man possesses an innate capacity for constructing symbols with which *some* sense can be expressed, without having the slightest idea what each word signifies. The best example of this is mathematics, for man has until lately used the symbols for numbers without knowing what they signify or that they signify nothing. [Cf. 5.43.]

Russell's "complexes" were to have the useful property of being compounded, and were to combine with this the agreeable property that they could be treated like "simples". But this alone made them

unserviceable as logical types, since there would have been significance in asserting, of a simple, that it was complex. But a *property* cannot be a logical type.

Every statement about apparent complexes can be resolved into the logical sum of a statement about the constituents and a statement about the proposition which describes the complex completely. How, in each case, the resolution is to be made, is an important question, but its answer is not unconditionally necessary for the construction of logic. [Cf. 2.0201.]

That "or" and "not" etc. are not relations in the same sense as "right" and "left" etc., is obvious to the plain man. The possibility of cross-definitions in the old logical indefinables shows, of itself, that these are not the right indefinables, and, even more conclusively, that they do not denote relations. [Cf. 5.42.]

If we change a constituent a of a proposition $\phi(a)$ into a variable, then there is a class

$$\hat{p}\{(\exists x).\phi(x) = p\}$$

This class in general still depends upon what, by an *arbitrary convention*, we mean by " $\phi(x)$ ". But if we change into variables all those symbols whose significance was arbitrarily determined, there is still such a class. But this is not dependent upon any convention, but only upon the nature of the symbol " $\phi(x)$ ". It corresponds to a logical type. [Cf. 3.315.]

Types can never be distinguished from each other by saying (as is often done) that one has these *but* the other has those properties, for this presupposes that there is a *meaning* in asserting all these properties of both types. But from this it follows that, at best, these properties may be types, but certainly not the objects of which they are asserted. [Cf. 4.1241.]

At a pinch we are always inclined to explanations of logical functions of propositions which aim at introducing into the function either only the constituents of these propositions, or only their form, etc. etc.; and we overlook that ordinary language would not contain the whole propositions if it did not need them: However, e.g., "not p " may be explained, there must always be a meaning given to the question "what is denied?"

The very possibility of Frege's explanations of "not- p " and "if p then q ", from which it follows that "not-not- p " denotes the same as p , makes it probable that there is some method of designation in which "not-not- p " corresponds to the same symbol as " p ". But if this method of designation suffices for logic, it must be the right one.

Names are points, propositions arrows--they have *sense*. The sense

of a proposition is determined by the two poles *true* and *false*. The form of a proposition is like a straight line, which divides all points of a plane into right and left. The line does this automatically, the form of proposition only by convention. [Cf. 3.144.]

Just as little as we are concerned, in logic, with the relation of a name to its meaning, just so little are we concerned with the relation of a proposition to reality, but we want to know the meaning of names and the sense of propositions--as we introduce an indefinable concept "A" by saying: "'A' denotes something indefinable", so we introduce e.g. the form of propositions aRb by saying: "For all meanings of 'x' and 'y', 'xRy' expresses something indefinable about x and y".

In place of every proposition " p ", let us write " $\hat{b}P$ ": Let every correlation of propositions to each other or of names to propositions be effected by a correlation of their poles " a " and " b ". Let this correlation be transitive. Then accordingly " $\hat{b} = \hat{b}P$ " is the same symbol as " $\hat{b}P$ ". Let n propositions be given. I then call a "class of poles" of these propositions every class of n members, of which each is a pole of one of the n propositions, so that one member corresponds to each proposition. I then correlate with each class of poles one of two poles (a and b). The sense of the symbolizing fact thus constructed I cannot define, but I know it.

If $p = \text{not-not-}p$ etc., this shows that the traditional method of symbolism is wrong, since it allows a plurality of symbols with the same sense; and thence it follows that, in analyzing such propositions, we must not be guided by Russell's method of symbolizing.

Page 102

It is to be remembered that names are not things, but classes: "A" is the same letter as "A". This has the most important consequences for every symbolic language. [Cf. 3.203].

Page 102

Neither the sense nor the meaning of a proposition is a thing. These words are incomplete symbols.

Page 102

It is impossible to dispense with propositions in which the same argument occurs in different positions. It is obviously useless to replace $\phi(a,a)$ by $\phi(a,b).a = b$.

Page 102

Since the *ab*-functions of p are again bi-polar propositions, we can form *ab*-functions of them, and so on. In this way a series of propositions will arise, in which in general the *symbolizing* facts will be the same in several members. If now we find an *ab*-function of such a kind that by repeated application of it every *ab*-function can be generated, then we can introduce the totality of *ab*-functions as the totality of those that are generated by application of this function. Such a function is $\sim p \vee \sim q$.

Page 102

It is easy to suppose a contradiction in the fact that on the one hand every possible complex proposition is a simple *ab*-function of simple

Page Break 103

propositions, and that on the other hand the repeated application of one *ab*-function suffices to generate all these propositions. If e.g. an affirmation can be generated by double negation, is negation in any sense contained in affirmation? Does "p" deny "not-p" or assert "p", or both? And how do matters stand with the definition of " \supset " by " \vee " and ".", or of " \vee " by "." and " \supset "? And how e.g. shall we introduce $p|q$ (i.e. $\sim p \vee \sim q$), if not by saying that this expression says something indefinable about all arguments p and q ? But the *ab*-functions must be introduced as follows: The function $p|q$ is merely a mechanical instrument for constructing all possible *symbols* of *ab*-functions. The symbols arising by repeated application of the symbol "|" do *not* contain the symbol " $p|q$ ". We need a rule according to which we can form all symbols of *ab* functions, in order to be able to speak of the class of them; and now we speak of them e.g. as those symbols of functions which can be generated by repeated application of the operation "|". And we say now: For all p 's and q 's, " $p|q$ " says something indefinable about the sense of those simple propositions which are contained in p and q . [Cf. 5.44.]

Page 103

The assertion-sign is logically quite without significance. It only shows, in Frege and Whitehead and Russell, that these authors hold the propositions so indicated to be true. " \vdash " therefore belongs as little to the proposition as (say) the number of the proposition. A proposition cannot possibly assert of itself that it is true. [Cf. 4.442.]

Page 103

Every right theory of judgment must make it impossible for me to judge that this table penholders the book. Russell's theory does not satisfy this requirement. [See 5.5422.]

Page 103

It is clear that we understand propositions without knowing whether they are true or false. But we can only know the *meaning* of a proposition [[sic]] when we know if it is true or false. What we understand is the *sense* of the proposition. [Cf. 4.024.]

Page 103

The assumption of the existence of logical objects makes it appear remarkable that in the sciences propositions of the form " $p \vee q$ ", " $p \supset q$ ", etc. are only then not provisional when " \vee " and " \supset " stand within the scope of a generality-sign [apparent variable].

FOURTH MS

Page 103

If we formed all possible atomic propositions, the world would be completely described if we declared the truth or falsehood of each. [Cf. 4.26.]

Page 103

The chief characteristic of my theory is that, in it, p has the same *meaning* as not- p . [Cf. 4.0621.]

Page 103

A false theory of relations makes it easily seem as if the relation of

fact and constituent were the same as that of fact and fact which follows from it. But the similarity of the two may be expressed thus:

$$\phi a. \supset_{\phi, a} a = a.$$

If a word creates a world so that in it the principles of logic are true, it thereby creates a world in which the whole of mathematics holds; and similarly it could not create a world in which a proposition was true, without creating its constituents. [Cf. 5.123.]

Signs of the form " $p \vee \sim p$ " are senseless, but not the proposition " $(p).p \vee \sim p$ ". If I know that this rose is either red or not red, I know nothing. The same holds of all *ab*-functions. [Cf. 4.461.]

To understand a proposition means to know what is the case if it is true. Hence we can understand it without knowing if it is true. We understand it when we understand its constituents and forms. If we know the meaning of "a" and "b", and if we know what "xRy" means for all x's and y's, then we also understand "aRb". [Cf. 4.024.]

I understand the proposition "aRb" when I know that either the fact that aRb or the fact that not aRb corresponds to it; but this is not to be confused with the false opinion that I understood "aRb" when I know that "aRb or not aRb" is the case.

But the form of a proposition symbolizes in the following way: Let us consider symbols of the form "xRy"; to these correspond primarily pairs of objects, of which one has the name "x", the other the name "y". The x's and y's stand in various relations to each other, among others the relation R holds between some, but not between others. I now determine the sense of "xRy" by laying down: when the facts behave in regard to \dagger 1 "xRy" so that the meaning of "x" stands in the relation R to the meaning of "y", then I say that the [the facts] are "of like sense" ["gleichsinnig"] with the proposition "xRy"; otherwise, "of opposite sense" ["entgegengesetzt"]; I correlate the facts to the symbol "xRy" by thus dividing them into those of like sense and those of opposite sense. To this correlation corresponds the correlation of name and meaning. Both are psychological. Thus I understand the form "xRy" when I know that it discriminates the behaviour of x and y according as these stand in the relation R or not. In this way I extract from all possible relations the relation R, as, by a name, I extract its meaning from among all possible things.

Strictly speaking, it is incorrect to say: we understand the proposition p when we know that "'p' is true" \equiv p ; for this would naturally always be the case if accidentally the propositions to right and left of the symbol " \equiv " were both true or both false. We require not only an

equivalence, but a formal equivalence, which is bound up with the introduction of the form of p .

The sense of an *ab*-function of p is a function of the sense of p . [Cf. 5.2341.]

The *ab*-functions use the discrimination of facts, which their arguments bring forth, in order to generate new discriminations.

Only facts can express sense, a class of names cannot. This is easily shown.

There is no thing which is the form of a proposition, and no name which is the name of a form. Accordingly we can also not say that a relation which in certain cases holds between things holds sometimes between forms and things. This goes against Russell's theory of judgment.

It is very easy to forget that, though the propositions of a form can be either true or false, each one of these propositions can only be either true or false, not both.

Among the facts which make "p or q" true, there are some which make "p and q" true; but the class which makes "p or q" true is different from the class which makes "p and q" true; and only this is what matters. For we

introduce this class, as it were, when we introduce *ab*-functions. [Cf. 5.1241.]

Page 105

A very natural objection to the way in which I have introduced e.g. propositions of the form xRy is that by it propositions such as $(\exists x.y).xRy$ and similar ones are not explained, which yet obviously have in common with aRb what cRd has in common with aRb . *But* when we introduce propositions of the form xRy we mentioned no one particular proposition of this form; and we only need to introduce $(\exists x,y).\phi(x,y)$ for all ϕ 's in any way which makes the sense of these propositions dependent on the sense of all propositions of the form $\phi(a,b)$, and thereby the justness of our procedure is proved.

Page 105

The indefinables of logic must be independent of each other. If an indefinable is introduced, it must be introduced in all combinations in which it can occur. We cannot therefore introduce it first for one combination, then for another; e.g., if the form xRy has been introduced it must henceforth be understood in propositions of the form aRb just in the same way as in propositions such as $(\exists x,y).xRy$ and others. We must not introduce it first for one class of cases, then for the other; for it would remain doubtful if its meaning was the same in both cases, and there would be no ground for using the same matter of combining symbols in both cases. In short for the introduction of indefinable symbols and combinations of symbols the same holds, *mutatis mutandis*, that Frege has said for the introduction of symbols by definitions. [Cf. 5.451.]

Page Break 106

Page 106

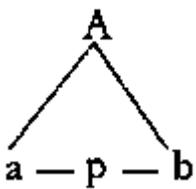

It is *a priori* likely that the introduction of atomic propositions is fundamental for the understanding of all other kinds of propositions. In fact the understanding of general propositions obviously depends on that of atomic propositions.

Page 106

Cross-definability in the realm of general propositions leads to quite similar questions to those in the realm of *ab*-functions.

Page 106

When we say "A believes p ", this sounds, it is true, as if here we could substitute a proper name for " p "; but we can see that here a *sense*, not a meaning, is concerned, if we say "A believes that ' p ' is true"; and in order to make the direction of p even more explicit, we might say "A believes that ' p ' is true and 'not- p ' is false". Here the bipolarity of p is expressed, and it seems that we shall only be able to express the proposition "A believes p " correctly by the *ab*-notation; say by making "A" have a relation to the poles "a" and "b" of a- p -b. The epistemological questions concerning the nature of judgment and belief cannot be solved without a correct apprehension of the form of the proposition.

Page 106

The *ab*-notation shows the dependence of *or* and *not*, and thereby that they are not to be employed as simultaneous indefinables.

Page 106

Not: "The complex sign 'ago'" says that a stands in the relation R to b ; but *that* ' a ' stands in a certain relation to ' b ' says *that* aRb . [3.1432.]

Page 106

In philosophy there are no deductions: *it* is purely descriptive.

Page 106

Philosophy gives no pictures of reality.

Page 106

Philosophy can neither confirm nor confute scientific investigation.

Page 106

Philosophy consists of logic and metaphysics: logic is its basis.

Page 106

Epistemology is the philosophy of psychology. [Cf. 4.1121.]

Page 106

Distrust of grammar is the first requisite for philosophizing.

Page 106

Propositions can never be indefinables, for they are always complex. That also words like "ambulo" are complex appears in the fact that their root with a different termination gives a different sense. [Cf. 4.032.]

Page 106

Only the doctrine of general indefinables permits us to understand the nature of functions. Neglect of this doctrine leads to an impenetrable thicket.

Page 106

Philosophy is the doctrine of the logical form of scientific propositions (not only of primitive propositions).

Page 106

The word "philosophy" ought always to designate something over or under but not beside, the natural sciences. [Cf. 4.111.]

Page Break 107

Page 107

Judgment, command and question all stand on the same level; but all have in common the propositional form, which does interest *us*.

Page 107

The structure of the proposition must be recognized, the rest comes of itself. But ordinary language conceals the structure of the proposition: in it, relations look like predicates, predicates like names, etc.

Page 107

Facts cannot be *named*.

Page 107

It is easy to suppose that "individual", "particular", "complex" etc. are primitive ideas of logic. Russell e.g. says "individual" and "matrix" are "primitive ideas". This error presumably is to be explained by the fact that, by employment of variables instead of the generality-sign, it comes to seem as if logic dealt with things which have been deprived of all properties except thing-hood, and with propositions deprived of all properties except complexity. We forget that the indefinables of symbols [*Urbilder von Zeichen*] only occur under the generality-sign, never outside it.

Page 107

Just as people used to struggle to bring all propositions into the subject-predicate form, so now it is natural to conceive every proposition as expressing a relation, which is just as incorrect. What is justified in this desire is fully satisfied by Russell's theory of manufactured relations.

Page 107

One of the most natural attempts at solution consists in regarding "not-*p*" as "the opposite of *p*", where then "opposite" would be the indefinable relation. But it is easy to see that every such attempt to replace the *ab*-functions by descriptions must fail.

Page 107

The false assumption that propositions are names leads us to believe that there must be logical objects: for the meanings of logical propositions will have to be such things.

Page 107

A correct explanation of logical propositions must give them a unique position as against all other propositions.

Page 107

No proposition can say anything about itself, because the symbol of the proposition cannot be contained in itself; this must be the basis of the theory of logical types. [Cf. 3.332.]

Page 107

Every proposition which says something indefinable about a thing is a subject-predicate proposition; every proposition which says something indefinable about two things expresses a dual relation between these things, and so on. Thus every proposition which contains only one name and one indefinable form is a subject-predicate proposition, and so on. An indefinable simple symbol can only be a name, and therefore we can know, by the symbol of an atomic proposition, whether it is a subject-predicate proposition.

Page Break 108

APPENDIX II

NOTES DICTATED TO G. E. MOORE IN NORWAY†1

Page 108

LOGICAL so-called propositions *shew* [the] logical properties of language and therefore of [the] Universe, but *say* nothing. [Cf. 6.12.]

Page 108

This means that by merely looking at them you can *see* these properties; whereas, in a proposition proper, you cannot see what is true by looking at it. [Cf. 6.113.]

Page 108

It is impossible to *say* what these properties are, because in order to do so, you would need a language, which hadn't got the properties in question, and it is impossible that this should be a *proper* language. Impossible to construct [an] illogical language.

Page 108

In order that you should have a language which can express or *say* everything that *can* be said, this language must have certain properties; and when this is the case, *that* it has them can no longer be said in that language or *any* language.

Page 108

An illogical language would be one in which, e.g., you could put an *event* into a hole.

Page 108

Thus a language which *can* express everything *mirrors* certain properties of the world by these properties which it must have; and logical so-called propositions shew *in a systematic way* those properties.

Page 108

How, usually, logical propositions do shew these properties is this: We give a certain description of a kind of symbol; we find that other symbols, combined in certain ways, yield a symbol of this description; and *that* they do shews something about these symbols.

Page 108

As a rule the description given in ordinary Logic is the description of a tautology; but *others* might shew equally well, e.g., a contradiction. [Cf. 6.1202.]

Page 108

Every *real* proposition *shews* something, besides what it says, about the Universe: *for*, if it has no sense, it can't be used; and if it has a sense, it mirrors some logical property of the Universe.

Page 108

E.g., take ϕa , $\phi a \supset \psi a$, ψa . By merely looking at these three, I can see that 3 follows from 1 and 2; i.e. I can see what is called the truth of a logical proposition, namely, of [the] proposition $\phi a. \phi a \supset \psi a: \supset: \psi a$. But this is *not* a proposition; but by seeing that it is a tautology I can

Page Break 109

see what I already saw by looking at the three propositions: the difference is that I *now* see THAT it is a tautology. [Cf. 6.1221.]

Page 109

We want to say, in order to understand [the] above, what properties a symbol must have, in order to be a tautology.

Page 109

Many ways of saying this are possible:

Page 109

One way is to give *certain symbols*; then to give a set of rules for combining them; and then to say: any symbol formed from those symbols, by combining them according to one of the given rules, is a tautology. This obviously says something about the kind of symbol you can get in this way.

Page 109

This is the actual procedure of [the] *old* Logic: it gives so-called primitive propositions; so-called rules of deduction; and then says that what you get by applying the rules to the propositions is a *logical* proposition that you have *proved*. The truth is, it tells you something *about* the kind of proposition you have got, viz that it can be derived from the first symbols by these rules of combination (= is a tautology).

Page 109

Therefore, if we say one *logical* proposition *follows* logically from another, this means something quite different from saying that a *real* proposition follows logically from *another*. For so-called *proof* of a logical proposition does not prove its *truth* (logical propositions are neither true nor false) but proves *that* it is a logical

proposition = is a tautology. [Cf. 6.1263.]

Page 109

Logical propositions *are forms of proofs*: they shew that one or more propositions *follow* from one (or more). [Cf. 6.1264.]

Page 109

Logical propositions *shew* something, *because* the language in which they are expressed can *say* everything that can be *said*.

Page 109

This same distinction between what can be *shewn* by the language but not *said*, explains the difficulty that is felt about types--e.g., as to [the] difference between things, facts, properties, relations. That M is a *thing* can't be *said*; it is nonsense: but *something* is *shewn* by the symbol "M". In [the] same way, that a *proposition* is a subject-predicate proposition can't be said: but it is *shown* by the symbol.

Page 109

Therefore a THEORY *of types* is impossible. It tries to say something about the types, when you can only talk about the symbols. But *what* you say about the symbols is not that this symbol has that type, which would be nonsense for [the] same reason: but you say simply: *This* is the symbol, to prevent a misunderstanding. E.g., in "aRb", "R" is *not* a symbol, but *that* "R" is between one name and another symbolizes. Here we have *not* said: this symbol is not of this type but of that, but only: *This* symbolizes and not that. This seems again to make the same

Page Break 110

mistake, because "symbolizes" is "typically ambiguous". The true analysis is: "R" is no proper name, and, that "R" stands between "a" and "b" expresses a *relation*. Here are two propositions *of different type* connected by "and".

Page 110

It is *obvious* that, e.g., with a subject-predicate proposition, *if* it has any sense at all, you *see* the form, so soon as you *understand* the proposition, in spite of not knowing whether it is true or false. Even if there *were* propositions of [the] form "M is a thing" they would be superfluous (tautologous) because what this tries to say is something which is already *seen* when you see "M".

Page 110

In the above expression "aRb", we were talking only of this particular "R", whereas what we want to do is to talk of all similar symbols. We have to say: in *any* symbol of this form what corresponds to "R" is not a proper name, and [the] fact that ["R" stands between "a" and "b"] expresses a relation. This is what is sought to be expressed by the nonsensical assertion: Symbols like this are of a certain type. This you can't say, because in order to say it you must first know what the symbol is: and in knowing this you *see* the type and therefore also [the] type of [what is] symbolized. I.e. in knowing *what* symbolizes, you know all that is to be known; you can't *say* anything *about* the symbol.

Page 110

For instance: Consider the two propositions (1) "What symbolizes here is a thing", (2) "What symbolizes here is a relational fact = relation". These are nonsensical for two reasons: (a) because they mention "thing" and "relation"; (b) because they mention them in propositions of the same form. The two propositions must be expressed in entirely different forms, if properly analysed; and neither the word "thing" nor "relation" must occur.

Page 110

Now we shall see how properly to analyse propositions in which "thing", "relation", etc., occur.

Page 110

(1) Take ϕx . We want to explain the meaning of 'In " ϕx " a *thing* symbolizes'. The analysis is:--

Page 110

$(\exists y)$. y symbolizes. y = "x". " ϕx "

Page 110

["x" is the name of y: " ϕx " = " ϕ " is at [the] left of "x" and *says* ϕx .]

Page 110

N.B. "x" can't be the name of this actual scratch y, because this isn't a thing: but it can be the name of a *thing*; and we must understand that what we are doing is to explain what would be meant by saying of an ideal symbol, which did actually consist in one *thing's* being to the left of another, that in it a *thing* symbolized.

Page Break 111

Page 111

[N.B. In [the] expression $(\exists y).\phi y$, one is apt to say this means "There is a *thing* such that... ". But in fact we should say "There is a y, such that... "; the fact that the y symbolizes expressing what we mean.]

In general: When such propositions are analysed, while the words "thing", "fact", etc. will disappear, there will appear instead of them a new symbol, of the same form as the one of which we are speaking; and hence it will be at once obvious that we *cannot* get the one kind of proposition from the other by substitution.

In our language names are *not things*: we don't know what they are: all we know is that they are of a different type from relations, etc. etc.. The type of a symbol of a relation is partly fixed by [the] type of [a] symbol of [a] thing, since a symbol of [the] latter type must occur in it.

N.B. In any ordinary proposition, e.g., "Moore good", this *shews* and does not say that "*Moore*" is to the left of "good"; and *here what* is shewn can be *said* by another proposition. But this only applies to that *part* of what is shewn which is arbitrary. The *logical* properties which it shews are not arbitrary, and that it has these cannot be said in any proposition.

When we say of a proposition of [the] form "aRb" that what symbolizes is that "R" is between "a" and "b", it must be remembered that in fact the proposition is capable of further analysis because a, R, and b are not *simples*. But what seems certain is that when we have analysed it we shall in the end come to propositions of the same form in respect of the fact that they do consist in one thing being between two others.†1

How can we talk of the general form of a proposition, without knowing any unanalysable propositions in which particular names and relations occur? What justifies us in doing this is that though we don't know any unanalysable propositions of this kind, yet we can understand what is meant by a proposition of the form $(\exists x, y, R).xRy$ (which is unanalysable), even though we know no proposition of the form xRy .

If you had any unanalysable proposition in which particular names and relations occurred (and *unanalysable* proposition = one in which only fundamental symbols = ones not capable of *definition*, occur) then you always can form from it a proposition of the form $(\exists x, y, R).xRy$, which though it contains no particular names and relations, is unanalysable.

(2) The point can here be brought out as follows. Take ϕa and ϕA :

and ask what is meant by saying, "There is a thing in ϕa , and a complex in ϕA "?

(1) means: $(\exists x).\phi x.x = a$

(2) $(\exists x, \psi \xi).\phi A = \psi x.\phi x.\dagger 1$

Use of logical propositions. You may have one so complicated that you cannot, by looking at it, see that it is a tautology; but you have shewn that it can be derived by certain operations from certain other propositions according to our rule for constructing tautologies; and hence you are enabled to see that one thing follows from another, when you would not have been able to see it otherwise. E.g., if our tautology is of [the] form $p \supset q$ you can see that q follows from p ; and so on.

The *Bedeutung* of a proposition is the fact that corresponds to it, e.g., if our proposition be "aRb", if it's true, the corresponding fact would be the fact aRb, if false, the fact $\sim aRb$. *But* both "the fact aRb" and "the fact $\sim aRb$ " are incomplete symbols, which must be analysed.

That a proposition has a relation (in wide sense) to Reality, other than that of *Bedeutung*, is shewn by the fact that you can understand it when you don't know the *Bedeutung*, i.e. don't know whether it is true or false. Let us express this by saying "It has *sense*" (*Sinn*).

In analysing *Bedeutung*, you come upon *Sinn* as follows:

We want to explain the relation of propositions to reality.

The relation is as follows: Its *simples* have meaning = are names of simples; and its relations have a quite

different relation to relations; and these two facts already establish a sort of correspondence between a proposition which contains these and only these, and reality: i.e. if all the simples of a proposition are known, we already know that we CAN describe reality by saying that it *behaves*†2 in a certain way to the whole proposition. (This amounts to saying that we can *compare* reality with the proposition. In the case of two lines we can *compare* them in respect of their length without any convention: the comparison is automatic. But in our case the possibility of comparison depends upon the conventions by which we have given meanings to our simples (names and relations).)

Page 112

It only remains to fix the method of comparison by saying *what* about our simples is to *say* what about reality. E.g., suppose we take two lines of unequal length; and say that the fact that the shorter is of the length it is is to mean that the longer is of the length *it* is. We should then have established a convention as to the meaning of the shorter, of the sort we are now to give.

Page Break 113

Page 113

From this it results that "true" and "false" are not accidental properties of a proposition, such that, when it has meaning, we can say it is also true or false: on the contrary, to have meaning *means* to be true or false: the being true or false actually constitutes the relation of the proposition to reality, which we mean by saying that it has meaning (*Sinn*).

Page 113

There seems at first sight to be a certain ambiguity in what is meant by saying that a proposition is "true", owing to the fact that it seems as if, in the case of different propositions, the way in which they correspond to the facts to which they correspond is quite different. But what is really common to all cases is that they must have *the general form of a proposition*. In giving the general form of a proposition you are explaining what kind of ways of putting together the symbols of things and relations will correspond to (be analogous to) the things having those relations in reality. In doing thus you are saying what is meant by saying that a proposition is true; and you must do it once for all. To say "This proposition *has sense*" means "'This proposition is true' means....' ('p' is true = 'p'. p. Def.: only instead of 'p' we must here introduce the general form of a proposition.)†1

Page 113

It seems at first sight as if the ab notation must be wrong, because it seems to treat true and false as on exactly the same level. It must be possible to see from the symbols themselves that there is some essential difference between the poles, if the notation is to be right; and it seems as if in fact this was impossible.

Page 113

The interpretation of a symbolism must not depend upon giving a different interpretation to symbols of the same types.

Page 113

How asymmetry is introduced is by giving a description of a particular form of symbol which we call a "tautology". The description of the ab-symbol alone is symmetrical with respect to a and b; but this description plus the fact that what satisfies the description of a tautology *is* a tautology is asymmetrical with regard to them. (To say that a description was symmetrical with regard to two symbols, would mean that we could substitute one for the other, and yet the description remain the same, i.e. mean the same.)

Page 113

Take p.q and q. When you write p.q in the ab notation, it is impossible to see from the symbol alone that q follows from it, for if you were to interpret the true-pole as the false, the same symbol would stand for $p \vee q$, from which q doesn't follow. But the moment you

Page Break 114

say *which* symbols are tautologies, it at once becomes possible to see from the fact that they are and the original symbol that q does follow.

Page 114

Logical propositions, OF COURSE, all shew something different: all of them shew, *in the same way*, viz by the fact that they are tautologies, but they are different tautologies and therefore shew each something different.

Page 114

What is unarbitrary about our symbols is not them, nor the rules we give; but the fact that, having given certain rules, others are fixed = follow logically. [Cf. 3.342.]

Thus, though it would be possible to interpret the form which we take as the form of a tautology as that of a contradiction and vice versa, they *are* different in logical form because though the apparent form of the symbols is the same, what *symbolizes* in them is different, and hence what follows about the symbols from the one interpretation will be different from what follows from the other. But the difference between a and b is *not* one of logical form, so that nothing will follow from this difference alone as to the interpretation of other symbols. Thus, e.g., $p, q, p \vee q$ seem symbols of exactly the *same* logical form in the ab notation. Yet they say something entirely different; and, if you ask why, the answer seems to be: In the one case the scratch at the top has the shape b, in the other the shape a. Whereas the interpretation of a tautology as a tautology is an interpretation of a *logical form*, not the giving of a meaning to a scratch of a particular shape. The important thing is that the interpretation of the form of the symbolism must be fixed by giving an interpretation to its *logical properties*, *not* by giving interpretations to particular scratches.

Logical constants can't be made into variables: because in them *what* symbolizes is *not* the same; all symbols for which a variable can be substituted symbolize in the *same* way.

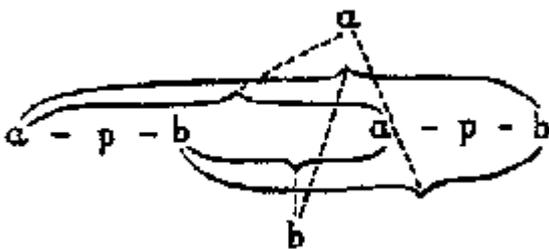

We describe a symbol, and say arbitrarily "A symbol of this description is a tautology". And then, it follows at once, both that any other symbol which answers to the same description is a tautology, and that any symbol which does *not* isn't. That is, we have arbitrarily fixed that any symbol of that description is to be a tautology; and this being fixed it is no longer arbitrary with regard to any other symbol whether it is a tautology or not.

Having thus fixed what is a tautology and what is not, we can then, having fixed arbitrarily again that the relation a-b is transitive get from the two facts together that " $p \equiv \sim(\sim p)$ " is a tautology. For $\sim(\sim p) = a-b-a-p-b-a-b$. The point is: that the process of reasoning by which we arrive at the result that a-b-a-p-b-a-b is the *same symbol* as a-p-b, is

exactly the same as that by which we discover that its meaning is the same, viz where we reason if b-a-p-b-a, then *not* a-p-b, if a-b-a-p-b-a-b then *not* b-a-p-b-a, therefore if a-b-a-p-b-a-b, then a-p-b.

It follows from the fact that a-b is transitive, that where we have a-b-a, the first a has to the second the same relation that it has to b. It is just as from the fact that a-true implies b-false, and b-false implies c-true, we get that a-true implies c-true. And we shall be able to see, having fixed the description of a tautology, that $p \equiv \sim(\sim p)$ is a tautology.

That, when a certain rule is given, a symbol is tautological *shews* a logical truth.

This symbol might be interpreted either as a tautology or a contradiction.

In settling that it is to be interpreted as a tautology and not as a contradiction, I am not assigning a *meaning* to a and b; i.e. saying that they symbolize different things but in the same way. What I am doing is to say that the way in which the a-pole is connected with the whole symbol symbolizes in a *different way* from that in which it would symbolize if the symbol were interpreted as a contradiction. And I add the scratches a and b merely in order to shew in which ways the connexion is symbolizing, so that it may be evident that wherever the same scratch occurs in the corresponding place in another symbol, there also the connexion is symbolizing in the same way.

We could, of course, symbolize any ab-function without using two *outside* poles at all, merely, e.g., omitting the b-pole; and here what would symbolize would be that the three pairs of inside poles of the propositions were connected in a certain way with the a-pole, while the other pair was *not* connected with it. And thus the difference

between the scratches a and b, where we do use them, merely shews that it is a different state of things that is symbolizing in the one case and the other: in the one case that certain inside poles *are* connected in a certain way with an outside pole, in the other *that* they're *not*.

Page Break 116

Page 116

The symbol for a tautology, in whatever form we put it, e.g., whether by omitting the a-pole or by omitting the b, would always be capable of being used as the symbol for a contradiction; only *not* in the same language.

Page 116

The reason why $\sim x$ is meaningless, is simply that we have given no meaning to the symbol $\sim \xi$. I.e. whereas ϕx and ϕp look as if they were of the same type, they are not so because in order to give a meaning to $\sim x$ you would have to have some *property* $\sim \xi$. What symbolizes in $\phi \xi$ is *that* ϕ stands to the left of a proper name and obviously this is not so in $\sim p$. What is common to all propositions in which the name of a property (to speak loosely) occurs is that this name stands to the left of a *name-form*.

Page 116

The reason why, e.g., it seems as if "Plato Socrates" might have a meaning, while "Abracadabra Socrates" will never be suspected to have one, is because we know that "Plato" has one, and do not observe that in order that the whole phrase should have one, what is necessary is *not* that "Plato" should have one, but that the fact *that* "Plato" is to the left of a name should.

Page 116

The reason why "The property of not being green is not green" is *nonsense*, is because we have only given meaning to the fact that "green" stands to the right of a name; and "the property of not being green" is obviously not *that*.

Page 116

ϕ cannot possibly stand to the left of (or in any other relation to) the symbol of a property. For the symbol of a property, e.g., ψx is *that* ψ stands to the left of a name form, and another symbol ϕ cannot possibly stand to the left of such a *fact*: if it could, we should have an illogical language, which is impossible.

p is false = $\sim(p$ is true) Def.

Page 116

It is very important that the apparent logical relations \vee , \supset , etc. need brackets, dots, etc., i.e. have "ranges"; which by itself shews they are not relations. This fact has been overlooked, because it is so universal--the very thing which makes it so important. [Cf. 5.461.]

Page 116

There are *internal* relations between one proposition and another; but a proposition cannot have to another *the* internal relation which a *name* has to the proposition of which it is a constituent, and which ought to be meant by saying it "occurs" in it. In this sense one proposition can't "occur" in another.

Page 116

Internal relations are relations between types, which can't be expressed in propositions, but are all shewn in the symbols themselves, and can be exhibited systematically in tautologies. Why we come to

Page Break 117

call them "relations" is because logical propositions have an analogous relation to them, to that which properly relational propositions have to relations.

Page 117

Propositions can have many different internal relations to one another. *The* one which entitles us to deduce one from another is that if, say, they are ϕa and $\phi a \supset \psi a$, then $\phi a. \phi a \supset \psi a \supset \psi a$ is a tautology.

Page 117

The symbol of identity expresses the internal relation between a function and its argument: i.e. $\phi a = (\exists x). \phi x. x = a$.

Page 117

The proposition $(\exists x). \phi x. x = a \equiv \phi a$ can be seen to be a tautology, if one expresses the *conditions* of the truth of $(\exists x). \phi x. x = a$, successively, e.g., by saying: This is true *if* so and so; and this again is true *if* so and so, etc., for $(\exists x). \phi x. x = a$; and then also for ϕa . To express the matter in this way is itself a cumbrous notation, of which the *ab*-notation is a neater translation.

Page 117

What symbolizes in a symbol, is that which is common to all the symbols which could in accordance with

the rules of logic = syntactical rules for manipulation of symbols, be substituted for it. [Cf. 3.344.]

Page 117

The question whether a proposition has sense (*Sinn*) can never depend on the *truth* of another proposition about a constituent of the first. E.g., the question whether $(x) x = x$ has meaning (*Sinn*) can't depend on the question whether $(\exists x) x = x$ is *true*. It doesn't describe reality at all, and deals therefore solely with symbols; and it says that they must *symbolize*, but not *what* they symbolize.

Page 117

It's obvious that the dots and brackets are symbols, and obvious that they haven't any *independent* meaning. You must, therefore, in order to introduce so-called "logical constants" properly, introduce the general notion of *all possible* combinations of them = the general form of a proposition. You thus introduce both ab-functions, identity, and universality (the three fundamental constants) simultaneously.

Page 117

The *variable proposition* $p \supset p$ is not identical with the *variable proposition* $\sim(p.\sim p)$. The corresponding universals *would* be identical. The variable proposition $\sim(p.\sim p)$ shews that out of $\sim(p.q)$ you get a tautology by substituting $\sim p$ for q , whereas the other does not shew this.

Page 117

It's very important to realize that when you have two different relations $(a,b)_R, (c,d)_S$ this does *not* establish a correlation between a and c , and b and d , or a and d , and b and c : there is no correlation whatsoever thus established. Of course, in the case of two pairs of terms united by the *same* relation, there is a correlation. This shews that the theory which held that a relational fact contained the terms and

Page Break 118

relations united by a *copula* (ϵ_2 is untrue; for if this were so there would be a correspondence between the terms of different relations.

Page 118

The question arises how can one proposition (or function) occur in another proposition? The proposition or function itself can't possibly stand in relation to the other symbols. For this reason we must introduce functions as well as names at once in our general form of a proposition; explaining what is meant, by assigning meaning to the fact that the names stand between the $|, \dagger 1$ and that the function stands on the left of the names.

Page 118

It is true, in a sense, that logical propositions are "postulates"--something which we "demand"; for we *demand* a satisfactory notation. [Cf. 6.1223.]

Page 118

A tautology (*not* a logical proposition) is not nonsense in the same sense in which, e.g., a proposition in which words which have no meaning occur is nonsense. What happens in it is that all its simple parts have meaning, but it is such that the connexions between these paralyse or destroy one another, so that they are all connected only in some irrelevant manner.

Page 118

Logical functions all presuppose one another. Just as we can see $\sim p$ has no sense, if p has none; so we can also say p has none if $\sim p$ has none. The case is quite different with ϕa , and a ; since here a has a meaning independently of ϕa , though ϕa presupposes it.

Page 118

The logical constants seem to be complex-symbols, but on the other hand, they can be interchanged with one another. They are not therefore really complex; what symbolizes is simply the general way in which they are combined.

Page 118

The combination of symbols in a tautology cannot possibly correspond to any one particular combination of their meanings--it corresponds to every possible combination; and *therefore what* symbolizes can't be the connexion of the symbols.

Page 118

From the fact that I *see* that one spot is to the left of another, or that one colour is darker than another, it seems to follow that it *is* so; and if so, this can only be if there is an *internal* relation between the two; and we might express this by saying that the *form* of the latter is part of the *form* of the former. We might thus give a sense to the assertion that logical laws are *forms* of thought and space and time *forms* of intuition.

Different logical types can have nothing whatever in common. But the mere fact that we can talk of the possibility of a relation of n places, or of an analogy between one with two places and one with four, shews that relations with different numbers of places have something in common, that therefore the difference is not one of type, but like the difference between different names--something which depends on experience. This answers the question how we can know that we have really got the most general form of a proposition. We have only to introduce what is *common* to all relations of whatever number of places.

The relation of "I believe p " to " p " can be compared to the relation of " p " says (besagt) p to p : it is just as impossible that I should be as simple as that " p " should be. [Cf. 5.542.]

APPENDIX III

EXTRACTS FROM WITTGENSTEIN'S LETTERS TO RUSSELL, 1912-20

Cambridge, 22.6.12.

... Logic is still in the melting pot but one thing gets more and more obvious to me: The propositions of Logic contain ONLY *apparent* variables and whatever may turn out to be the proper explanation of apparent variables, its consequences *must* be that there are NO *logical* constants.

Logic must turn out to be a *totally* different kind than any other science.

1.7.12.

... Will you think that I have gone mad if I make the following suggestion?: The sign " $(x).\phi x$ " is not a complete symbol but has meaning only in an inference of the kind: from $\vdash \phi x \supset_x \psi x$ follows ψa . Or more general: from $\vdash (x).\phi x$ follows $\phi(a)$. I am--of course--most uncertain about the matter but something of the sort might really be true.

Hochreit, Post Hohenberg, Nieder-Österreich. (Summer, 1912.)

... What troubles me most at present, is not the apparent-variable-business, but rather the meaning of " \vee " " \supset " etc. This latter problem is--I think--still more fundamental and, if possible, still less recognized as a problem. If " $p \vee q$ " means a complex at all--which is quite doubtful--then, as far as I can see, one must treat " \vee " as *part* of a copula in the way we have talked over before. I have--I believe--tried all possible ways of solution *under that hypothesis* and found that if any one will do it *must* be something like this:

Let us write the proposition "from $\vdash p$ and $\vdash q$ follows $\vdash r$ " that way: " $i(p; q; r)$ ". Here " i " is a copula (we may call it inference) which copulates *complexes*.

Then " $\vdash (\epsilon_1(x,y) \vee \epsilon_1(u,z))$ " is to mean:

" $\vdash (\epsilon_1(x,y), \epsilon_1(z,u), \beta(x,y,z,u)).i[\epsilon_1(x,y); \epsilon_1(z,u); \beta(x,y,z,u)]$
 $\vdash (\epsilon_1(x,y), \epsilon_1(z,u), \beta(x,y,z,u)).i[\sim\epsilon_1(x,y); \epsilon_1(z,u); \beta(x,y,z,u)]$
 $\vdash (\epsilon_1(x,y), \epsilon_1(z,u), \beta(x,y,z,u)).i[\epsilon_1(x,y); \sim\epsilon_1(z,u); \beta(x,y,z,u)]$
 $\vdash (\epsilon_1(x,y), \epsilon_1(z,u), \beta(x,y,z,u)).i[\sim\epsilon_1(x,y); \sim\epsilon_1(z,u); \beta(x,y,z,u)]$
 $\vdash (x,y,z,u)"$.

If " $p \vee q$ " does not mean a complex, then heaven knows what it means!!

August, 1912.

... Now as to 'p∨q' etc: I have thought that possibility--namely that all our troubles could be overcome by assuming different sorts of Relations of signs to things--over and over and over again! for the last eight weeks!!! But I have come to the conclusion that this assumption does *not* help us a bit. In fact if you work out any such theory--I believe you will see that *it does not even touch our problem*. I have lately seen a new way out (or perhaps not out) of the difficulty. It is too long to be explained here, but I tell you so much, that it is based on new forms of propositions. For instance: $\sim|\sim (p,q)$, which is to mean 'the complex p has the opposite form of q's form'. That means that $\sim|\sim (p,q)$ holds for instance when p is $\epsilon_1 (a,b)$ and q is $\sim\epsilon_1 (c,d)$. Another instance of the new forms is $\forall (p,q,r)$ which means something like: "The form of the complex r is composed of the forms of p and q in the way 'or'". That means that $\forall (p,q,r)$ holds for instance when p is $\epsilon_1 (a,b)$, q is $\epsilon_1 (c,d)$ and r is $\epsilon_1 (e,f) \vee \epsilon_1 (g,h)$ etc. etc. The rest I leave to your imagination.

1912.

Page 121

I believe that our problems can be traced down to the *atomic* propositions. This you will see if you try to explain precisely in what way the Copula in such a proposition has meaning.

Page 121

I cannot explain it and I think that as soon as an exact answer to this question is given the problem of " \vee " and of the apparent variable will be brought *very* near to their solution if not solved. I now think about "Socrates is human" (Good old Socrates!).

IV Alleegasse 16. Wien. 26.12.12.

Page 121

... I had a long discussion with Frege about our theory of symbolism of which, I think, he roughly understood the general outline. He said he would think the matter over. The complex-problem is now clearer to me and I hope very much that I may solve it.

IV Alleegasse 16. Jan. 1913.

Page 121

... I have changed my views on "atomic" complexes: I now think that qualities, relations (like love) etc. are all copulae! That means I for instance analyse a subject-predicate proposition, say, "Socrates is

Page Break 122

human" into "Socrates" and "something is human", (which I think is not complex). The reason for this is a very fundamental one: I think that there cannot be different Types of things! In other words whatever can be symbolized by a simple proper name must belong to one type. And further: every theory of types must be rendered superfluous by a proper theory of symbolism: For instance if I analyse the proposition Socrates is mortal into Socrates, mortality and $(\exists x,y) \epsilon_1 (x,y)$ I want a theory of types to tell me that "mortality is Socrates" is nonsensical, because if I treat "mortality" as a proper name (as I did) there is nothing to prevent me to make the substitution the wrong way round. *But* if I analyse (as I do now) into Socrates and $(\exists x).x$ is mortal or generally into x and $(\exists x)\phi x$ it becomes impossible to substitute the wrong way round because the two symbols are now of a different *kind* themselves. What I am *most* certain of is not however the correctness of my present way of analysis, but of the fact that all theory of types must be done away with by a theory of symbolism showing that what seem to be *different kinds of things* are symbolized by different kinds of symbols which *cannot* possibly be substituted in one another's places. I hope I have made this fairly clear!

Page 122

Propositions which I formerly wrote $\epsilon_2 (a,R,b)$ I now write $R(a,b)$ and analyse them into a,b and

$(\exists x,y) R(x,y)$
not complex

June, 1913.

Page 122

... I can now express my objection to your theory of judgement exactly: I believe it is obvious that, from the proposition "A judges that (say) a is in a relation R to b", if correctly analysed, the proposition "a R b.∨.~a R b" must follow directly *without the use of any other premiss*. This condition is not fulfilled by your theory.

Hochreit, Post Hohenberg, Nieder-Österreich, 22.7.13.

Page 122

... My work goes on well; every day my problems get clearer now and I feel rather hopeful. All my progress comes out of the idea that the *indefinables* of Logic are of the general kind (in the same way as the so-called *definitions* of Logic are general) and this again comes from the abolition of the real variable.

Page 122

... I am very sorry to hear that my objection to your theory of judgment paralyses you. I think it can only be removed by a correct theory of propositions.

Page Break 123

Hochreit, Post Hohenberg, N.-Ö.

Page 123

(This letter seems to have been written sometime near to that of the letter dated 22.7.13.)

Page 123

Your axiom of reducibility is

$$\vdash :(\exists f):[f]x \equiv_x f!x;$$

now is this not all nonsense as this proposition has only then a meaning if we can turn the ϕ into an *apparent* variable. For if we cannot do so no general laws can ever follow from your axiom. The whole axiom seems to me at present a mere juggling trick. Do let me know if there is more in it. The axiom as you have put it is only a schema and the real Pp ought to be

$$\vdash :.(\phi):(\exists f):\phi(x) \equiv_x f!x,$$

and where would be the use of that?--

5.9.13.

Page 123

I am sitting here in a little place inside a beautiful fiord and thinking about the beastly theory of types. There are still some *very* difficult problems (and very fundamental ones too) to be solved and I won't begin to write until I have got some sort of a solution for them. However I don't think that will in any way affect the bipolarity business which still seems to me to be absolutely untangible.

c/o Draegni, Skjolden, Sogn, Norway. 29.10.13.

Page 123

... Identity is the very Devil and *immensely important*; *very* much more so than I thought. It hangs--like everything else--directly together with the most fundamental questions, especially with the questions concerning the occurrence of the *same* argument in different places of a function. I have all sorts of ideas for a solution of the problem but could not yet arrive at anything definite. However, I don't lose courage and go on thinking.

30.10.

Page 123

I wrote this†1 letter yesterday. Since then quite new ideas have come into my mind; new problems have arisen in the theory of molecular propositions and the theory of inference has received a new and very important aspect. One of the consequences of my new ideas will--I think--be that the whole of Logic follows from one Pp only!! I cannot say more about it at present.

Page Break 124

1913.

Page 124

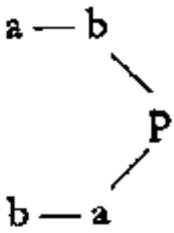

Thanks for your letter and the typed stuff!†1 I will begin by answering your questions as well as I can:

Page 124

(1) Your question was--I think due to the misprint (polarity instead of *bi*-polarity). What I mean to say is that we *only* then understand a proposition if we know *both* what would be the case if it was *false* and what if it was *true*.

Page 124

(2) The symbol for $\sim p$ is a-b-p-a-b. The proposition p has two poles and it does not matter a hang where they stand. You might just as well write $\sim p$ like this

or $b \rightarrow a \rightarrow p \rightarrow b \rightarrow a$ etc. etc. All that *is* important is that the new a -pole should be correlated to the old b -pole and vice versa *wherever these old poles may stand*. If you had only remembered the WF scheme of $\sim p$ you would never have asked this question (I think). In fact all rules of the ab symbolism follow directly from the essence of the WF scheme.

Page 124

(3) Whether ab -functions and your truth-functions are the same cannot yet be decided.

Page 124

(4) "The correlation of new poles is to be transitive" means that by correlating one pole in the symbolizing way to another and the other to a third we have *thereby* correlated the first in the symbolizing way to the third, etc.. For instance in $a-b-a-b-p-a-b-a-b$, a and b are correlated to b and a respectively and this means that our symbol is the same as $a-b-p-a-b$.

Page 124

(5) $(p) p \vee \sim p$ is derived from *the function* $p \vee \sim q$ but the point will only become quite clear when identity is clear (as you said). I will some other time write to you about this matter at length.

Page 124

(6) Explanation in the typed stuff.

Page 124

(7) You say, you thought that *Bedeutung* was the "fact", this is quite true, but remember that there are no such things as facts and that therefore this proposition itself wants analysing. If we speak of "die *Bedeutung*" we seem to be speaking of a thing with a proper name. Of course the symbol for "a fact" is a proposition and this is *no* incomplete symbol.

Page Break 125

Page 125

(8) The exact $a-b$ indefinable is given in the manuscript.

Page 125

(9) An account of general indefinables? Oh Lord! It is too boring!!! Some other time!--Honestly--I *will* write to you about it some time, if by that time you have not found out all about it (because it is all quite clear in the manuscript I think). But just now I am *so* troubled with Identity that I really cannot write any long jaw. All sorts of new logical stuff seems to be growing in me, but I can't yet write about it.

Page 125

... The following is a list of the questions you asked me in your letter of the 25th.10.:

Page 125

(1) "What is the point of ' $p \equiv$. "p" is true'? I mean why is it worth saying?"

Page 125

(2) "If ' apb ' is the symbol for p , is ' bpa ' the symbol for $\sim p$? and if not, what is?"

Page 125

(3) "What you call ab -functions are what the Principia calls 'truth-functions'. I don't see why you shouldn't stick to the name 'truth-functions'."

Page 125

(4) "I don't understand your rules about a 's and b 's, i.e. 'the correlation of new poles is to be transitive'."

Page 125

(5) (Is obvious from my letter) so is (6).

Page 125

(7) "You say 'Weder der Sinn noch die *Bedeutung* eines Satzes ist ein Ding. Jene Worte sind unvollständige Zeichen". I understand neither being a *thing*, but I thought the *Bedeutung* was the *fact*, which is surely not indicated by an incomplete symbol?"

Page 125

I don't know whether I have answered the question (7) clearly. The answer is *of course* this: The *Bedeutung* of a proposition is symbolized by the proposition--which is *of course* not an incomplete symbol, *but the word*

"Bedeutung" is an incomplete symbol.

Page 125

(8) and (9) are obvious.

Nov., 1913.

Page 125

... I beg you to notice that, although I shall make use in what follows of my ab notation, the meaning of this notation is not needed; that is to say, even if this notation should turn out not to be the final correct notation what I am going to say is valid if you only admit--as I believe you must do--that it is a *possible* notation. Now listen! I will first talk about those logical propositions which are or might be contained in the first 8 chapters of Principia Mathematica. That they all follow from *one* proposition is clear because *one symbolic* rule is

Page Break 126

sufficient to recognize each of them as true or false. And this is the *one* symbolic rule: write the proposition down in the ab notation, trace all connections (of poles) from the outside to the inside poles: Then if the b-pole is connected to such *groups of inside poles only as contain opposite poles of one proposition*, then the whole proposition is a true, logical proposition. If on the other hand this is the case with the a-pole the proposition is false and logical. If finally neither is the case the proposition may be true or false, but it is in no case logical. Such for instance $(p).\sim p$ --p transmuted to a suitable type, of course--is not a logical proposition at all and its truth can neither be proved nor disproved from logical propositions alone. The same is the case--by the way--with your axiom of reducibility, *it is not a logical proposition at all* and the same applies to the axioms of infinity and the multiplicative axiom. *If these are true propositions they are what I shall call "accidentally" true and not "essentially" true.* Whether a proposition is accidentally or essentially true can be seen by writing it down in the ab notation and applying the above rule. What I--in stating this rule--called "logical" proposition is a proposition which is either essentially true or essentially false. This distinction of accidentally and essentially true propositions explains--by the way--the feeling one always had about the infinity axiom and the axiom of reducibility, the feeling that if they were true they would be so by a lucky accident.

Page 126

Of course the rule I have given applies first of all only for what you called elementary propositions. But it is easy to see that it must also apply to all others. For consider your two Pps in the theory of apparent variables *9.1 and *9.11. Put then instead of $\phi x, (\exists y).\phi y.y = x$ and it becomes obvious that the special cases of these two Pps like those of all the previous ones become tautologous if you apply the ab notation. The ab Notation for Identity is not yet clear enough to show this clearly but it is obvious that such a Notation can be made up. I can sum up by saying that a logical proposition is one the special cases of which are either tautologous--and then the proposition is true--or self-contradictory (as I shall call it) and then it is false. And the ab notation simply shows directly which of these two it is (if any).

Page 126

That means that there is *one* method of proving or disproving all logical propositions and this is: writing them down in the ab notation and looking at the connections and applying the above rule. But if *one* symbolic rule will do, there must also be *one* Pp that will do. There is much that follows from all this and much that I could only explain vaguely but if you really think it over you will find that I am right.

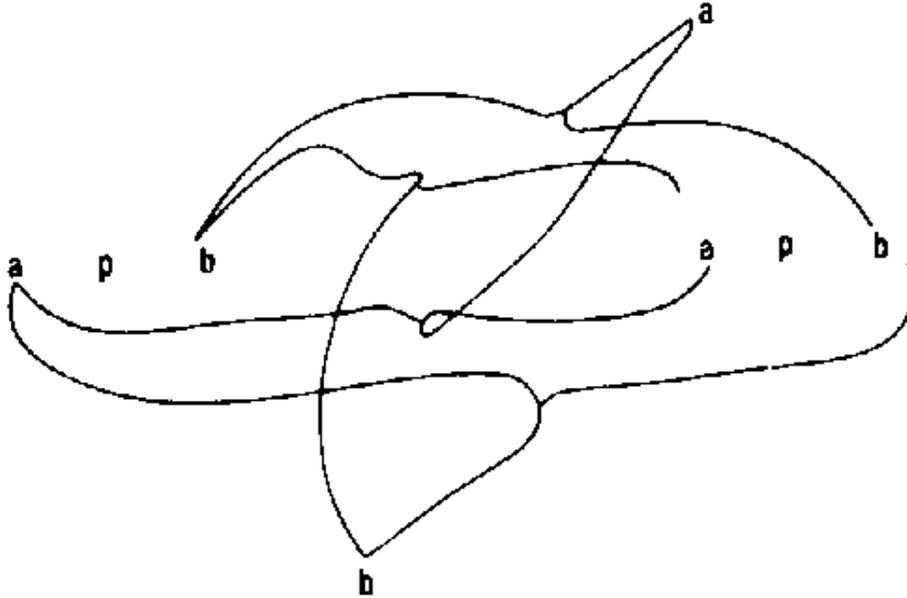

Page Break 127

Norway, 1913.

Page 127

... Ich will dasjenige, was ich in meinem letzten Brief über Logik schrieb, noch einmal in anderer Weise wiederholen: Alle Sätze der Logik sind Verallgemeinerungen von Tautologien and alle Verallgemeinerungen von Tautologien sind Sätze der Logik. Andere logische Sätze gibt es nicht. (Dies halte ich für definitiv). Ein Satz wie " $(\exists x).x = x$ " zum Beispiel ist eigentlich ein Satz der Physik. Der Satz " $(x):x = x.\supset.(\exists y).y = y$ " ist ein Satz der Logik; es ist nun Sache der Physik zu sagen, *ob es ein Ding gibt*. Dasselbe gilt vom infinity axiom; ob es \dot{A}_0 Dinge gibt, das zu bestimmen ist Sache der Erfahrung (und die kann es nicht entscheiden). Nun aber zu Deinem Reductions-Axiom: Stell' Dir vor, wir leben in einer Welt, worin es nichts als *Dinge* gäbe and außerdem *nur noch eine Relation*, welche zwischen unendlich vielen dieser Dinge bestehe and zwar so, daß sie nicht zwischen jedem Ding and jedem anderen besteht, and daß sie ferner auch nie zwischen einer endlichen Anzahl von Dingen besteht. Es ist klar, daß das axiom of reducibility in einer solchen Welt sicher *nicht* bestünde. Es ist mir aber auch klar, daß es nicht die Sache der Logik ist darüber zu entscheiden, ob die Welt worin wir leben nun wirklich so ist, oder nicht. Was aber Tautologien eigentlich sind, das kann ich selber noch nicht ganz klar sagen, will aber trachten es ungefähr zu erklären. Es ist das

eigentümliche (und *höchst* wichtige) Merkmal der *nicht*-logischen Sätze, daß man ihre Wahrheit *nicht* am Satzzeichen selbst erkennen kann. Wenn ich z. B. sage "Meier ist dumm", so kannst Du dadurch, daß Du diesen Satz anschaust, nicht sagen ob er wahr oder falsch ist. Die Sätze der Logik aber--und sie allein--haben die Eigenschaft, daß sich ihre Wahrheit bzw. Falschheit schon in ihrem Zeichen ausdrückt. Es ist mir noch nicht gelungen, für die Identität eine Bezeichnung zu finden, die dieser Bedingung genügt; aber *ich zweifle nicht*, daß sich eine solche Bezeichnungsweise finden lassen muß. Für zusammengesetzte Sätze (elementary propositions) genügt die ab-Bezeichnungsweise. Es ist mir unangenehm, daß Du die Zeichenregel an meinem letzten Brief nicht verstanden hast, denn es langweilt mich *unsagbar* sie zu erklären!! Du könntest sie auch durch ein bißchen Nachdenken selber finden!

Dies ist das Zeichen für $p \equiv p$; es ist tautologisch weil b nur mit solchen Polpaaren verbunden ist, welche aus den entgegengesetzten Polen eines Satzes (nämlich p) bestehen; wenn Du dies auf Sätze anwendest, die mehr als 2 Argumente haben so erhält Du die allgemeine Regel,

Page Break 128

wonach Tautologien gebildet werden. Ich bitte Dich denke selbst über die Sache nach, es ist mir *schrecklich* eine schriftliche Erklärung zu wiederholen, die ich schon zum ersten Mal mit dem allergrößten *Widerstreben* gegeben habe. Die Identität ist mir--wie gesagt--noch gar nicht klar. Also hierüber ein andermal! Wenn Dein Axiom of Reducibility fällt, so wird manches geändert werden müssen. Warum gebrauchst Du als Definition der Klassen nicht diese:

$$F[\hat{X}(\phi x)] =: \phi z \equiv z \psi x. \supset \psi. F(\psi) \text{ Def. } ?$$

... Die große Frage ist jetzt: Wie muß ein Zeichensystem beschaffen sein, damit es jede Tautologie *auf eine and dieselbe Weise* als Tautologie erkennen läßt? Dies ist das Grundproblem der Logik!

Page 128

... Ich will nur noch sagen, daß Deine Theorie der "Descriptions" *ganz zweifellos* richtig ist, selbst wenn die einzelnen Urzeichen darin ganz andere sind als Du glaubst.

Page 128

Translation of the above:

I want to repeat what I wrote about logic in my last letter, putting it in a different way: All propositions of logic are generalizations of tautologies and all generalizations of tautologies are propositions of logic. There are no logical propositions but these. (I consider this to be definitive.) A proposition like " $(\exists x)x = x$ " is for example really a proposition of physics. The proposition " $(x):x = x. \supset. (\exists y).y = y$ " is a proposition of logic: it is for physics to say *whether any thing exists*. The same holds of the infinity axiom; whether there are \hat{A}_0 things is for experience to settle (and experience can't decide it). But now for your reducibility axiom: Imagine our living in a world, where there is nothing but *things*, and besides *only one relation*, which holds between infinitely many of these things, but does not hold between every one and every other of them: further, it never holds between a finite number of things. It is clear that the axiom of reducibility would certainly *not* hold in such a world. But it is also clear to me that it is not for logic to decide whether the world we live in is actually like this or not. However, I can't myself say quite clearly yet what tautologies really are, but I'll try to give a rough account. It is the peculiar (and most important) characteristic of *non*-logical propositions, that their truth cannot be seen in the propositional sign itself. If I say for

... Now another question: Doesn't the "Principle of Sufficient Reason" (Law of Causality) simply say that space and time are relative? At present this seems to me to be quite clear; for all the events, whose occurrence this principle is supposed to exclude, could only occur at all in an absolute time and an absolute space. (This would not of course quite justify my assertion.) But think of the case of a particle, which was the only thing in the world and had been at rest from all eternity, and then suddenly begins to move at a moment of time A; and of similar cases: then you will see--or so I believe--that *no a priori* insight makes such events seem impossible to us, *except in the case* of space and time's being relative. Please write me your opinion on this point.

Cassino, 19.8.19.†1

(1) "What is the difference between *Tatsache* and *Sachverhalt*?" *Sachverhalt* is, what corresponds to an *Elementarsatz* if it is true. *Tatsache* is what corresponds to the logical product of elementary props when this product is true. The reason why I introduce *Tatsache* before introducing *Sachverhalt* would want a long explanation.

(2) "... But a *Gedanke* is a *Tatsache*: what are its constituents and components, and what is their relation to those of the pictured *Tatsache*?" I don't know *what* the constituents of a thought are but I know *that* it must have such constituents which correspond to the words of Language. Again the kind of relation of the constituents of the thought and of the pictured fact is irrelevant. It would be a matter of psychology to find out.

(3) "The theory of types, in my view, is a theory of correct symbolism: a simple symbol must not be used to express anything complex: more generally, a symbol must have the same structure as its meaning." That's exactly what one can't say. You cannot prescribe to a symbol

what it *may* be used to express. All that a symbol *can* express, it *may* express. This is a short answer but it is true!

(4) "Does a *Gedanke* consist of words?" No! But of *psychical* constituents that have the same sort of relation to reality as words. What those constituents are I don't know.

(5) "It is awkward to be unable to speak of $Nc^cV\ddagger 1$." This touches the cardinal question of what can be expressed by a prop, and what can't be expressed, but only shown. I can't explain it at length here. Just think that, what you want to *say* by the apparent proposition "There are 2 things" is *shown* by there being two names which have different meanings (or by there being one name which may have two meanings). A proposition e.g. $\phi(a,b)$ or $(\exists\phi,x,y).\phi(x,y)$ doesn't say that there are two things, it says something quite different; *but whether it's true or false, it shows* you what you want to *express* by saying: "there are 2 things".

(6) Of course no elementary props are negative.

(7) "It is necessary also to be given the proposition that all elementary propositions are given." This is not necessary because it is even impossible. There is no such proposition! That all elementary propositions are given is *shown* by there being none having an elementary sense which is not given. This is again the same story as in No. 5.

(8) I suppose you didn't understand the way how I separate in the old notation of generality what is in it truth-function and what is purely generality. A general proposition is a truth-function of *all propositions* of a certain form.

(9) You are quite right in saying that " $N(\xi)$ " may also be made to mean $\sim p \vee \sim q \vee \sim r \vee \dots$. But this doesn't matter! I suppose you don't understand the notation " ξ ". It does not mean "for all values of ξ ...". But all is said in my book about it and I feel unable to write it again.

9.4.20.

Besten Dank für Dein Manuskript.†2 Ich bin mit so manchem darin nicht ganz einverstanden; sowohl dort, wo Du mich kritisierst, als auch dort, wo Du bloß meine Ansicht klarlegen willst. Das macht aber nichts. Die Zukunft wird über uns urteilen. Oder auch nicht--und wenn sie schweigen wird, so wird das auch ein Urteil sein.

Many thanks for your manuscript. I am not quite in agreement with a lot of it: both where you criticize me, and where you are merely trying to expound my views. But it doesn't matter. The future will judge between us. Or it won't--and if it is silent, that will be a judgment too.

6.5.20.

... Nun wirst Du aber auf mich böse sein, wenn ich Dir etwas erzähle; Deine Einleitung wird nicht gedruckt and in folgedessen wahrscheinlich auch mein Buch nicht.--Als ich nämlich die deutsche Übersetzung der Einleitung vor mir hatte, da konnte ich mich doch nicht entschließen, sie mit meiner Arbeit drucken zu lassen. Die Feinheit Deines englischen Stils war nämlich in der Übersetzung--selbstverständlich--verloren gegangen and was übrig blieb, war Oberflächlichkeit and Mißverständnis. Ich schickte nun die Abhandlung and Deine Einleitung an Reclam und schrieb ihm, ich wünschte nicht, daß die Einleitung gedruckt würde, sondern sie solle ihm nur zur Orientierung über meine Arbeit dienen. Es ist nun höchst wahrscheinlich, daß Reclam meine Arbeit daraufhin nicht nimmt (obwohl ich noch keine Antwort von ihm habe).

... Now, however, you will be angry at what I have to tell you: your introduction will not be printed, and in consequence probably neither will my book. For when I got the German translation of the introduction, I couldn't bring myself to have it printed with my work after all. For the fineness of your English style was--of course--quite lost and what was left was superficiality and misunderstanding. Now I have sent the treatise and your introduction to Reclam, and have written to him that I did not want the introduction to be printed, but that he should just use it to orientate himself about my work. It is now extremely likely that in consequence Reclam will not take my work (although I have not had an answer from him yet).

APPENDIX IV†*

$$\exists x \exists y (x \neq y) = (x \neq y) = x \neq y$$

~~Proof~~ $\exists x \exists y (x \neq y) \Rightarrow \exists x \exists y (x \neq y)$

FOREWORD

This book is written for such men as are in sympathy with its spirit. This spirit is different from the one which informs the vast stream of European and American civilization in which all of us stand. That spirit expresses itself in an onwards movement, in building ever larger and more complicated structures; the other in striving after clarity and perspicuity in no matter what structure. The first tries to grasp the world by way of its periphery--in its variety; the second at its centre--in its essence. And so the first adds one construction to another, moving on and up, as it were, from one stage to the next, while the other remains where it is and what it tries to grasp is always the same.

Page 7

I would like to say 'This book is written to the glory of God', but nowadays that would be chicanery, that is, it would not be rightly understood. It means the book is written in good will, and in so far as it is not so written, but out of vanity, etc., the author would wish to see it condemned. He cannot free it of these impurities further than he himself is free of them.

ANALYTICAL TABLE OF CONTENTS

I

Page 9

1 A proposition is completely logically analysed if its grammar is made clear--in no matter what idiom. All that is possible and necessary is to separate what is essential from what is inessential in our language--which amounts to the construction of a phenomenological language. Phenomenology as the grammar of those facts on which physics builds its theories. 51

Page 9

2 The complexity of philosophy is not in its matter, but in our tangled understanding. 52

Page 9

3 How strange if logic were concerned with an 'ideal' language, and not with *ours*! 52

Page 9

4 If I could describe the point of grammatical conventions by saying they are made necessary by certain properties of the colours (say)--then what would make the conventions superfluous, since in that case I would be able to say precisely that which the conventions exclude my saying. 53

Page 9

5 Might we say: A child must of course learn to speak a particular language, but not to think? 53

Page 9

6 In a certain sense, the use of language is something that cannot be taught. 54

Page 9

7 Grammatical conventions cannot be justified by describing what is represented: any such description already presupposes the grammatical rules. 54

Page Break 10

Page 10

8 The kind of co-ordination on the basis of which a heard or seen language functions would be, say: 'If you hear a shot or see me wave, run.' 55

Page 10

9 Have philosophers hitherto always spoken nonsense? 55

II

Page 10

10 Thinking of propositions as instructions for making models. For it to be possible for an expression to guide my hand, it must have the same multiplicity as the action desired. And this must also explain the nature of negative propositions. 57

Page 10

11 How do I know that I can recognize red when I see it? How do I know it is the colour that I *meant*? 57

Page 10

12 If the image of the colour is not identical with the colour that is really seen, how can a comparison be made?

Page 10

13 Language must have the same multiplicity as a control panel that sets off the actions corresponding to its propositions. 58

Page 10

14 Only the application makes a rod into a lever.--Every instruction can be construed as a description, every description as an instruction. 59

Page 10

15 What does it mean, to understand a proposition as a member of a system of propositions? Its complexity is only to be explained by the use for which it is intended. 59

Page 10

16 How do I know that *that* was what I expected? How do I know that the colour which I now call 'white' is the same as the one I saw here yesterday? By recognizing it again. 59

Page 10

17 Should Logic bother itself with the question whether the

Page Break 11

proposition was merely automatic or thoroughly *thought*? It is interested in the proposition as part of a language system. 60

Page 11

18 I do not believe that logic can talk about sentences [propositions] in any other than the normal sense in which we say, 'There's a sentence written here'. 61

Page 11

19 Agreement of a proposition with reality. We can look at recognition, like memory, in two different ways: as a source of the concepts of the past and of identity, or as a way of checking what happened in the past, and on identity. 61

III

Page 11

20 If you exclude the element of intention from language, its whole function then collapses. 63

Page 11

21 The essential difference between the picture conception (of intention) and Russell's conception is that the former regards recognition as seeing an internal relation. The causal connection between speech and action is an external relation. 63

Page 11

22 I believe Russell's theory amounts to the following: if I give someone an order and I am happy with what he then does, then he has carried out my order. 64

Page 11

23 If, when learning a language, speech, as it were, is connected up to action, can these connections possibly break down? If so, what means have I for *comparing* the original arrangement with the subsequent action? 64

Page 11

24 The intention is already expressed in the way I *now* compare the picture with reality. 65

Page 11

25 Expecting that *p* will be the case must be the same as expecting the fulfilment of this expectation. 65

Page Break 12

Page 12

26 If there were only an external connection, no connection could be described at all, since we only describe the external connection by means of the internal one. 66

Page 12

27 The meaning of a question is the method of answering it. Tell me *how* you are searching, and I will tell you *what* you are searching for. 66

Page 12

28 Expecting is connected with looking for. I know what I am looking for, without what I am looking for having to

exist. The event that replaces an expectation is the reply to it. That of course implies that the expectation must be in the same space as what is expected. 67

Page 12

29 Expectation is not given an *external* description by citing what is expected; describing it by means of what is expected is giving an internal description. 68

Page 12

30 If I say 'This is the same event as I expected' and 'This is the same event as also happened on that occasion', then the word 'same' has a different meaning in each case. 68

Page 12

31 Language and intention. If you say, 'That's a brake lever, but it doesn't work', you are speaking of intention. 69

Page 12

32 I only use the terms expectation, thought, wish, etc. of something which is articulated. 69

Page 12

33 *How* you search in one way or another expresses what you expect. Expectation prepares a yardstick for measuring the event. If there were no connection between expectation and reality, you could expect a nonsense . 70

Page 12

34 If I say that the representation must treat of my world, then I cannot say 'since otherwise I could not verify it', but 'since otherwise it wouldn't even begin to make sense to me'. 71

Page 12

35 The strange thing about expectation is that we know it is an

Page Break 13

expectation. And *that* is what shows expectation is immediately connected with reality. We have to be able to give a description comparing expectation with the present. 72

Page 13

36 What I once called 'objects' were simply that which we can speak about *no matter what may be the case*. 'I expect three knocks on the door.' What if I replied, 'How do you know three knocks *exist*?' 72

Page 13

37 Is a man who cannot see any red around him at present in the same position as someone incapable of seeing red? If one of them imagines red, that is not a red he sees. 73

Page 13

38 The memory and the reality must be in *one* space. Also: the image and the reality are in *one* space. 73

IV

Page 13

39 If I can only see something black and say it isn't red, how do I know that I am not talking nonsense--i.e. that it could be red, that there is red--if red weren't just another graduation mark on the same scale as black? 75

Page 13

40 If there is a valid comparison with a ruler, the word 'blue' must give the direction in which I go from black to blue. But how do these different directions find expression in grammar? 75

Page 13

41 A man with red/green colour blindness has a different colour system from a normal man. Is the question then 'Can someone who doesn't know what red and green are like really see what we call "blue" and "yellow"?' 76

Page 13

42 Grey must already be conceived as being in lighter/darker space. The yardstick must already be applied: I cannot *choose* between *inner* hearing and *inner* deafness. 76

Page Break 14

Page 14

43 For any question there is always a corresponding *method* of finding. You cannot compare a picture with reality unless you can set it against it as a yardstick. 77

Page 14

44 How is a 'formally certified proposition' possible? The application of a yardstick doesn't presuppose any particular length for the object to be measured. That is why I can learn to measure in general.

78

Page 14

45 But are the *words* in the same space as the object whose length is described? The unit length is part of the symbolism, and *it* is what contains the specifically spatial element.

78

Page 14

46 A language using a co-ordinate system. The written sign without the co-ordinate system is senseless.

79

V

Page 14

47 It doesn't strike us at all when we look round us, move about in space, feel our own bodies, etc., etc., because there is nothing that contrasts with the form of our world. The self-evidence of the world expresses itself in the very fact that language can and does only refer to it.

80

Page 14

48 The stream of life, or the stream of the world, flows on and our propositions are so to speak verified only at instants. Then they are commensurable with the present.

80

Page 14

49 Perhaps the difficulty derives from taking the time concept from time in physics and applying it to the course of immediate experience. We don't speak of present, past and future images.

81

Page 14

50 'I do not see the past, only a *picture* of the past.' But how do I know it's a picture of the *past*?

82

Page Break 15

Page 15

51 On the film strip there is a present picture and past and future pictures: but on the screen there is only the present.

83

Page 15

52 We cannot say 'time flows' if by time we mean the possibility of change.--It also appears to us as though memory were a faint picture of what we originally had before us in full clarity. And in the language of physical objects that is so.

83

Page 15

53 But it can also be put *differently*; and that is important. The phrase 'optical illusion', for example, gives the idea of a mistake, even when there is none. One could imagine an absolutely *impartial* language.

84

Page 15

54 Language can only say those things that we can also imagine otherwise. That everything flows must be expressed in the *application* of language. And if someone says only the present *experience* has reality, then the word 'present' must be redundant here.

84

Page 15

55 Certain important propositions describing an experience which might have been otherwise: such as the proposition that my visual field is almost incessantly in a state of flux.

86

Page 15

56 If I make a proposition such as 'Julius Caesar crossed the Alps', do I merely describe my present mental state?--The proposition states what I believe. If I wish to know what that is, the best thing to do is to ask *why* I believe it.

86

VI

Page 15

57 One misleading representational technique in our language is the use of the word "I", particularly when it is used in representing immediate experience. How would it be if such experience were represented without using the personal pronoun?

88

Page Break 16

Page 16

58 Like this, say: If I, L. W., have toothache, that is expressed as 'There is toothache'. In other cases: 'A is behaving

as L. W. does when there is toothache'. Language can have anyone as its centre. That it has me as its centre lies in the application. This privileged status cannot be expressed. Whether I say that what is represented is *not* one thing among others; or that I cannot express the advantage of *my* language--both approaches lead to the same result. 88

Page 16

59 It isn't possible to believe something for which you cannot find some kind of verification. In a case where I believe someone is sad I can do this. But I cannot *believe* that *I* am sad. 89

Page 16

60 Does it make *sense* to say two people have the same body? 90

Page 16

61 What distinguishes *his* toothache from *mine*? 90

Page 16

62 'When I say he has toothache, I mean he now has what I once had.' But is this a relation toothache once had to me and now has to him? 91

Page 16

63 I could speak of toothache (datum of feeling) in someone else's tooth in the sense that it would be possible to feel pain in a tooth in someone else's mouth. 92

Page 16

64 If I say 'A has toothache', I use the image of feeling pain in the same way as, say, the concept of flowing when I talk of an electric current flowing.--The hypotheses that (1) other people have toothache and that (2) they behave just as I do but don't have toothache--possibly have identical senses. 93

Page 16

65 Our language employs the phrases 'my pain' and 'his pain' and also 'I have (or feel) a pain', but 'I feel my pain' or 'I feel his pain' is

Page Break 17

nonsense. 94

Page 17

66 What would it be like if I had two bodies, i.e. my body were composed of two separate organisms?--Philosophers who believe you can, in a manner of speaking, extend experience by thinking, ought to remember you can transmit speech over the telephone, but not measles. 95

VII

Page 17

67 Suppose I had such a good memory that I could remember all my sense impressions. I could then describe them, e.g. by representing the visual images plastically, only finishing them so far as I had actually seen them and moving them with a mechanism. 97

Page 17

68 If I describe a language, I am describing something that belongs to physics. But how can a physical language describe the phenomenal? 97

Page 17

69 A phenomenon (specious present) contains time, but isn't in time. Whereas language unwinds in time. 98

Page 17

70 We need a way of speaking with which we can represent the phenomena of visual space, isolated as such. 98

Page 17

71 Visual space is called subjective only in the language of physical space. The essential thing is that the representation of visual space is the representation of an object and contains no suggestion of a subject. 99

Page 17

72 How can I tell that I see the world through the pupil of my eyeball? Surely not in an essentially different way from that of my seeing it through the window. 100

Page 17

73 In visual space there isn't an eye belonging to me and eyes

Page Break 18

belonging to others. Only the space itself is asymmetrical. 102

74 The exceptional position of my body in visual space derives from other feelings, and not from something purely visual. 102

75 Is the time of isolated 'visual' phenomena the time of our ordinary idioms of physics? I imagine the changes in my visual space are discontinuous and in time with the beats of a metronome. I can then describe them and compare the description with what actually happens. A delusion of memory? No, a delusion that, *ex hypothesi*, cannot be unmasked isn't a delusion. And here the time of my memory is precisely the time I'm describing. 103

VIII

76 Incompatible for red and green to be in *one* place at the same time. What would a mixed colour of red and green be? And different degrees of red are also incompatible with one another.--And yet I can say: 'There's an even redder blue than the redder of these two'. That is, from the given I can construct what is not given.--Is a construction possible within the elementary proposition which doesn't work by means of truth functions and also has an effect on one proposition's following logically from another? In that case, two elementary propositions can contradict one another. 105

77 This is connected with the idea of a *complete description*. 106

78 That *r* and *g* completely occupy the *f*--that doesn't show itself in our signs. But it must show itself if we look, not at the sign, but at the symbol. For since this includes the form of the objects, then the impossibility of '*f*(*r*)•*f*(*g*)' must show itself there in this form. 106

79 That would imply I can write down two particular propositions, but not their logical product? We can say that the '•' has a different meaning here. 107

80 A mixed or intermediate colour of blue and red is such in virtue of an internal relation to the structures of red and blue. But this internal relation is *elementary*. That is, it doesn't consist in the proposition '*a* is blue-red' representing a logical product of '*a* is blue' and '*a* is red'. 107

81 As with colours, so with sounds or electrical charges. It's always a question of the complete description of a certain state at *one* point or at the same time. But how can I express the fact that e.g. a colour is definitively described? How can I bring it about that a second proposition of the same form contradicts the first?--Two elementary propositions can't contradict one another. 108

82 There are rules for the truth functions which also deal with the elementary part of the proposition. In which case propositions become even more like yardsticks. The fact that *one* measurement is right automatically excludes all others. It isn't a proposition that I put against reality as a yardstick, it's a system of propositions. Equally in the case of negative description: I can't be given the zero point without the yardstick. 109

83 The concept of the independent co-ordinates of description. The propositions joined e.g. by 'and' are not independent of one another, they form *one* picture and can be tested for their compatibility or incompatibility. 111

84 In that case every assertion would consist in setting a number of scales (yardsticks), and it's impossible to set one scale simultaneously at two graduation marks. 112

85 That all propositions contain time appears to be accidental when compared with the fact that the truth functions can be applied to any proposition. 112

86 Syntax prohibits a construction such as '*a* is green and *a* is red', but for '*a* is green' the proposition '*a* is red' is not,

so to speak, *another* proposition, but another form of the same proposition. In this way syntax draws together the propositions that make *one* determination. 113

IX

Page 20

87 The general proposition 'I see a circle on a red background'--a proposition which leaves possibilities open. What would this generality have to do with a totality of objects? Generality in this sense, therefore, enters into the theory of elementary propositions. 115

Page 20

88 If I describe only a part of my visual field, my description must necessarily include the whole visual space. The form (the logical form) of the patch in fact presupposes the whole space. 115

Page 20

89 Can I leave some determination in a proposition open, without at the same time specifying precisely what possibilities are left open? 'A red circle is situated in the square.' How do I know such a proposition? Can I ever know it as an endless disjunction? 116

Page 20

90 Generality and negation. 'There is a red circle that is not in the square.' I cannot express the proposition 'This circle is not in the square' by placing the 'not' *at the front of* the proposition. That is connected with the fact that it's nonsense to give a circle a name. 116

Page 20

91 'All circles are in the square' can mean either 'A certain number of circles are in the square' or: 'There is no circle outside it'. But the last proposition is again the negation of a generalization and not the generalization of a negation. 117

Page 20

92 The part of speech is only determined by *all* the grammatical

Page Break 21

rules which hold for a word, and seen from this point of view our language contains countless different parts of speech. 118

Page 21

93 The subject-predicate form does not in itself amount to a logical form. The forms of the propositions: 'The plate is round', 'The man is tall', 'The patch is red', have nothing in common.-- Concept and object: but that is subject and predicate. 118

Page 21

94 Once you have started doing arithmetic, you don't bother about functions and objects.--The description of an object may not express what would be essential for the existence of the object. 119

Page 21

95 If I give names to three visual circles of equal size--I always name (directly or indirectly) a *location*. What characterizes propositions of the form 'This is...' is only the fact that the reality outside the so-called system of signs somehow enters into the symbol. 119

Page 21

96 What remains in this case, if form and colour alter? For position is part of the form. It is clear that the phrase 'bearer of a property' conveys a completely wrong--an impossible--picture. 120

Page 21

97 Roughly speaking, the equation of a circle is the sign for the concept 'circle'. So it is as if what corresponds with the objects falling under the concept were here the co-ordinates of the centres. In fact, the number pair that gives the co-ordinates of the centre is not just anything, but characterizes just what in the symbol constitutes the 'difference' of the circles. 121

Page 21

98 The specification of the 'here' must not prejudge *what* is here. $F(x)$ must be an *external* description of x .--but if I now say 'Here is a circle' and on another occasion 'Here is a sphere', are the two 'here's' of the same kind? 122

Page Break 22

X

Page 22

99 Number and concept. Does it make sense to ascribe a number to objects that haven't been brought under a concept? But I can e.g. form the concept, 'link between a and b '. 123

Page 22

100 Numbers are pictures of the extensions of concepts. We could regard the extension of a concept as an object whose name has sense only in the context of a proposition. In the symbolism there is an actual correlation, whereas at the level of meaning only the possibility of correlation is at issue. 124

Page 22

101 I can surely always distinguish 3 and 4 in the sign $1 + 1 + 1 + 1 + 1 + 1 + 1$. 124

Page 22

102 Numbers can only be defined from propositional *forms*, independently of the question which propositions are true or false. The possibility of grouping these 4 apples into 2 and 2 refers to the sense, not the truth of a proposition. 125

Page 22

103 Can a proposition (A) in PM notation give the sense of $5 + 7 = 12$? But how have I obtained the numerical sign in the right-hand bracket if I don't know that it is the result of adding the two left-hand signs? 125

Page 22

104 What tells us that the 5 strokes and the 7 combine *precisely to make 12* is always only insight into the internal relations of the structures--not some logical consideration. 127

Page 22

105 An extension is a characteristic of the sense of a proposition. 127

Page 22

106 What A contains apart from the arithmetical schema can only be what is necessary in order to apply it. But nothing at all is necessary. 128

Page 22

107 No investigation of concepts can tell us that $3 + 2 = 5$;

Page Break 23

equally it is not an examination of concepts which tells us that A is a tautology. Numbers must be of a kind with what we use to represent them. 129

Page 23

108 Arithmetic is the grammar of numbers. 129

Page 23

109 Every mathematical calculation is an application of itself and only as such does it have a sense. *That* is why it isn't necessary to speak about the general form of logical operation here.--Arithmetic is a more general kind of geometry. 130

Page 23

110 It's as if we're surprised that the numerals cut adrift from their definitions function so unerringly; which is connected with the internal consistency of geometry. The general form of the application of arithmetic seems to be represented by the fact that *nothing* is said about it. 131

Page 23

111 Arithmetical constructions are autonomous, like geometrical ones, and hence they guarantee their own applicability. 132

Page 23

112 If 3 strokes on paper are the sign for the number 3, then you can say the number 3 is to be applied in the way in which 3 strokes can be applied. (Cf. §107) 133

Page 23

113 A statement of number about the extension of a concept is a proposition, but a statement of number about the range of a variable is not, since it can be derived from the variable itself. 133

Page 23

114 Do I know there are 6 permutations of 3 elements in the same way in which I know there are 6 people in this room? No. Therefore the first proposition is of a different *kind* from the second. 134

XI

Page 23

115 A statement of number doesn't always contain something general or indefinite. For instance, 'I see 3 equal circles equidistant from one another'. Something indefinite would be, say: I know that three things have the property ϕ , but I don't know *which*.

Page Break 24

Here it would be nonsense to say I don't know which *circles* they are. 136

Page 24

116 There is no such concept as 'pure colour'. Similarly with permutations. If we say that $A B$ admits of two permutations, it sounds as though we had made a general assertion. But 'Two permutations are possible' cannot say any less--i.e. something more general--than the schema $A B, B A$. They are not the extension of a concept: they are the concept. 137

Page 24

117 There is a mathematical question: 'How many permutations of 4 elements are there?' which is the same kind as 'What is 25×18 ?' For in both cases there is a general method of solution. 139

Page 24

118 In Russell's theory only an *actual* correlation can show the "similarity" of two classes. Not the *possibility* of correlation, for this consists precisely in the numerical equality. 140

Page 24

119 What sort of an *impossibility* is the impossibility of a 1-1 correlation between 3 circles and 2 crosses?--It is nonsense to say of an extension that it has such and such a number, since the number is an *internal* property of the extension. 140

Page 24

120 Ramsey explains the sign '=' like this: $x = x$ is taut.; $x = y$ is cont. What then is the relation of 'Def' to '='?--You may compare mathematical equations only with significant propositions, not with tautologies. 141

Page 24

121 An equation is a rule of syntax. You may construe sign-rules as propositions, but you don't *have to* construe them so. The 'heterological' paradox. 143

Page 24

122 The generality of a mathematical assertion is different from the generality of the proposition proved. A mathematical proposition is an allusion to a proof. A generalization only makes sense if it--i.e. all values of its variables--is completely determined. 143

Page Break 25

XII

Page 25

123 I grasp an infinite stretch in a different way from an endless one. A proposition about it can't be verified by a putative endless striding, but only in *one* stride. 146

Page 25

124 It isn't just impossible 'for us men' to run through the natural numbers one by one; it's *impossible*, it means nothing. The totality is only given as a concept. 146

Page 25

125 That, in the case of the logical concept $(1, \xi, \xi + 1)$, the existence of its objects is already given with the concept, of itself shows that it determines them. What is fundamental is simply the repetition of an operation. The operation $+ 1$ three times yields and *is* the number 3. 147

Page 25

126 It looks now as if the quantifiers make no sense for numbers. 148

Page 25

127 If no finite product makes a proposition true, that means *no* product makes it true. And so it *isn't* a logical product. 148

Page 25

128 Can I know that a number satisfies the equation without a finite section of the infinite series being marked out as one within which it occurs? 149

Page 25

129 A proposition about all propositions, or all functions, is impossible. *Generality* in arithmetic is indicated by an induction. 150

Page 25

130 The defect (circle) in Dedekind's explanation of the concept of infinity lies in its application of the concept 'all' in the formal implication. What really corresponds to what we mean isn't a proposition at all, it's the *inference* from ϕx to ψx , if this inference is permitted--but the inference isn't expressed by a proposition. 151

131 Generality in Euclidean geometry. Strange that what holds for one triangle should therefore hold for every other. But once more the construction of a proof is not an experiment; no, a description of the construction must suffice.--What is demonstrated can't be expressed by a proposition. 152

132 'The world will *eventually* come to an end' means nothing at all, for it's compatible with this statement that the world should still exist on any day you care to mention. 'How many 9s immediately succeed one another after 3.1415 in the development of π ?' If this question is meant to refer to the extension, then it doesn't have the sense of the question which interests us. ('I grasp an infinite stretch in a different way from an endless one.') 153

133 The difficulty in applying the simple basic principles shakes our confidence in the principles themselves. 153

134 'I saw the ruler move from t_1 to t_2 , *therefore* I must have seen it at t .' If in such a case I appear to infer a particular case from a general proposition, then the general proposition is never derived from experience, and the proposition isn't a real proposition. 154

135 'We only know the infinite by description.' Well then, there's just the description and nothing else. 155

136 Does a notation for the infinite presuppose infinite space or infinite time? Then the possibility of such a hypothesis must surely be prefigured somewhere. The problem of the smallest visible distinction. 155

137 If I cannot visibly bisect the strip any further, I can't even *try* to, and so can't see the failure of such an attempt. Continuity in our visual field consists in our not seeing discontinuity. 156

138 Experience as experience of the facts gives me the finite; the objects *contain* the infinite. Of course, not as something rivalling finite experience, but in intension. (Infinite possibility is *not* a quantity.) Space has no extension, only spatial objects are extended, but infinity is a property of space. 157

139 Infinite divisibility: we can conceive of *any* finite number of parts but not of an infinite number; but that is precisely what constitutes infinite divisibility.--That a patch in visual space can be divided into three parts means that a proposition describing a patch divided in this way makes sense. Whereas infinite divisibility doesn't mean there's a proposition describing a line divided into infinitely many parts. Therefore this possibility is not brought out by any reality of the signs, but by a possibility of a *different* kind in the signs themselves. 158

140 Time contains the possibility of all the future *now*. The space of human movement is infinite in the same way as time. 160

141 The rules for a number system--say, the decimal system--contain everything that is infinite about the numbers.--It all hangs on the syntax of reality and possibility. $m = 2n$ contains the *possibility of correlating any number* with another, *but doesn't correlate all numbers with others*. 161

142 The propositions 'Three things can lie in this direction' and 'Infinitely many things can lie in this direction' are only apparently formed in the same way, but are in fact different in structure: the 'infinitely many' of the second structure doesn't play the same role as the 'three' of the first. 162

143 Empty infinite time is only the possibility of facts which alone are the realities.--If there is an infinite reality, then there is also contingency in the infinite. And so, for instance, also an

infinite decimal that isn't given by a law.--Infinity lies in the nature of time, it isn't the extension it happens to have.

163

Page 28

144 The infinite number series is only the infinite possibility of finite series of numbers. The signs themselves only contain the possibility and not the reality of their repetition. Mathematics can't even try to speak about their possibility. If it tries to *express* their possibility, i.e. when it confuses this with their reality, we ought to cut it down to size.

164

Page 28

145 An infinite decimal not given by a rule. 'The number that is the result when a man endlessly throws a die', appears to be nonsense.--An infinite row of trees. If there is a law governing the way the trees' heights vary, then the series is defined and can be imagined by means of this law. If I now assume there could be a random series, then that is a series about which, by its very nature, nothing can be known apart from the fact that I can't know it.

165

Page 28

146 The multiplicative axiom. In the case of a finite class of classes we can in fact make a selection. But in the case of infinitely many sub-classes I can only know the law for making a selection. Here the infinity is only in the rule.

167

Page 28

147 What makes us think that perhaps there are infinitely many things is only our confusing the things of physics with the elements of knowledge. 'The patch lies somewhere between *b* and *c*': the infinite possibility of positions isn't expressed in the analysis of this.--The illusion of an infinite hypothesis in which the parcels of matter are confused with the simple objects. What we can imagine multiplied to infinity are the combinations of the things in accordance with their infinite possibilities, never the things themselves.

168

Page Break 29

XIII

Page 29

148 While we've as yet no idea how a certain proposition is to be proved, we still ask 'Can it be proved or not?' You cannot have a logical plan of search for a *sense* you don't know. Every proposition teaches us through its sense how we are to convince ourselves whether it is true or false.

170

Page 29

149 A proof of relevance would be a proof which, while yet not proving the proposition, showed the form of a method for testing the proposition.

170

Page 29

150 I can assert the general (algebraic) proposition just as much or as little as the equation $3 \times 3 = 9$ or $3 \times 3 = 11$. The general method of solution is in itself a clarification of the nature of the equation. Even in a particular case I see only the rule. 'The equation yields *a*' means: if I transform the equation in accordance with certain rules I get *a*. But these rules must be given to me before the word 'yields' has a meaning and before the question has a sense.

172

Page 29

151 We may only put a question in mathematics where the answer runs: 'I must work it out'. The question 'How many solutions are there to this equation?' is the holding in readiness of the general method for solving it. And that, in general, is what a question is in mathematics: the holding in readiness of a general method.

175

Page 29

152 I can't ask whether an angle can be trisected until I can see the system 'Ruler and Compasses' embedded in a larger one, where this question has a sense.--The system of rules determining a calculus thereby determines the 'meaning' of its signs too. If I change the rules, then I change the form, the meaning.--In mathematics, we cannot talk of systems in general, but only within systems.

177

Page 29

153 A mathematical proof is an analysis of a mathematical

Page Break 30

proposition. It isn't enough to say that *p* is provable, we have to say: provable according to a particular system. Understanding *p* means understanding its system.

179

Page 30

154 I can ask 'What is the solution of this equation?', but not 'Has it a solution?'--It's impossible for us to discover rules of a new type that hold for a form with which we are familiar.--The proposition: 'It's possible--though not

necessary--that p should hold for all numbers' is nonsense. For 'necessary' and 'all' belong together in mathematics.
181

Page 30

155 Finding a new system (Sheffer's discovery, for instance). You can't say: I already had all these results, now all I've done is find a better way that leads to all of them. The new way amounts to a new system.

182

Page 30

156 Unravelling knots in mathematics. We may only speak of a genuine attempt at a solution *to the extent* that the structure of the knot is clearly seen.

184

Page 30

157 You can't write mathematics, you can only do it.--Suppose I hit upon the right way of constructing a regular pentagon by accident. If I don't understand this construction, as far as I'm concerned it doesn't even begin to be the construction of a pentagon. The way I have arrived at it vanishes in what I understand.

186

Page 30

158 Where a connection is now known to exist which was previously unknown, there wasn't a gap before, something incomplete which has now been filled in.--Induction: if I know the law of a spiral, that's in many respects analogous with the case in which I know all the whorls. Yet not completely analogous--and that's all we can say.

Page 30

159 But doesn't it still count as a question, whether there is a finite number of primes or not? Once I can write down the general form of primes, e.g. 'dividing... by smaller numbers leaves a

Page Break 31

remainder'--there is no longer a question of 'how many' primes there are. But since it was possible for us to have the phrase 'prime number' before we had the strict expression, it was also possible for people to have wrongly formed the question. Only in our verbal language are there in mathematics 'as yet unsolved problems'.

188

Page 31

160 A consistency proof can't be essential for the application of the axioms. For these are propositions of syntax.

189

Page 31

161 A polar expedition and a mathematical one. How can there be conjectures in mathematics? Can I make a hypothesis about the distribution of primes? What kind of verification do I then count as valid? I can't conjecture the proof. And if I've got the proof it doesn't prove what was conjectured.

189

Page 31

162 Sheffer's discovery. The systems are certainly not in *one* space, so that I could say: there are systems with 3 and 2 logical constants, and now I'm trying to reduce the number of constants *in the same way*.--A mathematical proposition is only the immediately visible surface of a whole body of proof and this surface is the boundary facing us.

191

XIV

Page 31

163 A proof for the associative law? As a basic rule of the system it cannot be proved. The usual mistake lies in confusing the extension of its application with what the proof genuinely contains.--Can one prove that by addition of forms $((1 + 1) + 1)$ etc. numbers of this form would always result? The proof lies in the rule, i.e. in the definition and in nothing else.

193

Page 31

164 A recursive proof is only a general guide to arbitrary special proofs: the general form of continuing along this series. Its

Page Break 32

generality is not the one we desire but consists in the fact that we can repeat the proof. What we gather from the proof we cannot represent in a proposition at all.

196

Page 32

165 The correct expression for the associative law is not a proposition, but precisely its 'proof', which admittedly doesn't state the law. I know the specific equation is correct just as well as if I had given a complete derivation of it. That means it really is proved. The *one* whorl, in conjunction with the numerical forms of the given equation, is enough.

198

166 One says an induction is a sign that such and such holds for all numbers. But an induction isn't a sign for anything but itself.--Compare the generality of genuine propositions with generality in arithmetic. It is differently verified and so is of a different kind. 200

167 An induction doesn't prove an algebraic equation, but it justifies the setting up of algebraic equations from the standpoint of their application to arithmetic. That is, it is only through the induction that they gain their sense, not their truth. An induction is related to an algebraic proposition not as proof is to what is proved, but as what is designated to a sign. 201

168 If we ask 'Does $a + (b + c) = (a + b) + c$?', what could we be after?--An algebraic proposition doesn't express a generality; this is shown, rather, in the formal relation to the substitution, which proves to be a term of the inductive series. 202

169 One can prove any arithmetical equation of the form $a \times b = c$ or prove its opposite. A proof of this provability would be the exhibition of an induction from which it could be seen what sort of propositions the ladder leads to. 204

XV

170 The theory of aggregates says that you can't grasp the actual infinite by means of arithmetical symbolism at all, it can therefore only be described and not represented. So one could talk about a logical structure without reproducing it in the proposition itself. A method of wrapping a concept up in such a way that its form disappears. 206

171 Any proof of the continuity of a function must relate to a number system. The numerical scale, which comes to light when calculating a function, should not be allowed to disappear in the general treatment.--Can the continuum be described? A form cannot be described: it can only be presented. 207

172 'The highest point of a curve' doesn't mean 'the highest point among all the points of the curve'. In the same way, the maximum of a function isn't the largest value among all its values. No, the highest point is something I *construct*, i.e. derive from a law. 208

173 The expression '(n)...' has a sense if nothing more than the unlimited possibility of going on is presupposed.--Brouwer--. The explanation of the Dedekind cut as if it were clear what was meant by: either R has a last member and L a first, or, etc. In truth none of these cases can be conceived. 209

174 Set theory builds on a fictitious symbolism, therefore on nonsense. As if there were something in Logic that could be known, but not by us. If someone says (as Brouwer does) that for $(x) \cdot f_1x = f_2x$ there is, as well as yes and no, also the case of undecidability, this implies that '(x)...' is meant extensionally and that we may talk of all x happening to have a property. 211

175 If one regards the expression 'the root of the equation $\phi x = 0$ ' as a Russellian description, then a proposition about the

root of the equation $x + 2 = 6$ must have a different sense from one saying the same about 4. 213

176 How can a purely internal generality be refuted by the occurrence of a single case (and so by something extensional)? But the particular case refutes the general proposition from within--it attacks the internal proof.--The difference between the two equations $x^2 = x \cdot x$ and $x^2 = 2x$ isn't one consisting in the extensions of their validity. 214

XVI

177 That a point in the plane is represented by a number-pair, and in three-dimensional space by a number-triple, is

enough to show that the object represented isn't the point at all but the point-network.

216

Page 34

178 Geometry as the syntax of the propositions dealing with objects in space. Whatever is arranged in visual space stands in this *sort* of order *a priori*, i.e. in virtue of its logical nature, and geometry here is simply grammar. What the physicist sets into relation with one another in the geometry of physical space are instrument readings, which do not differ in their *internal* nature whether we live in a linear space or a spherical one.

216

Page 34

179 I can approach any point of an interval indefinitely by always carrying out the bisection prescribed by tossing a coin. Can I divide the rationals into two classes in a similar way, by putting either 0 or 1 in an infinite binary expansion according to the way the coin falls (heads or tails)? No law of succession is described by the instruction to toss a coin; and infinite indefiniteness does not define a number.

218

Page 34

180 Is it possible within the law to abstract from the law and see the extension presented as what is essential?--If I cut at a place

Page Break 35

where there is no rational number, then there must be approximations to this cut. But closer to what? For the time being I have nothing in the domain of number which I can approach.--All the points of a line can actually be represented by arithmetical rules. In the case of approximation by repeated bisection we approach *every* point via *rational* numbers.

221

XVII

Page 35

181 What criterion is there for the irrational numbers being *complete*? Every irrational number runs through a series of rational approximations, and never leaves this series behind. If I have the totality of all irrational numbers except π , and now insert π , I cannot cite a point at which π is really needed; at every point it has a companion agreeing with it. This shows clearly that an irrational number isn't the extension of an infinite decimal fraction, it's a law. If π were an extension, we would never feel the lack of it--it would be impossible for us to detect a gap.

223

Page 35

182 ' $\sqrt{2}$ ': a rule with an exception.--There must first be the rules for the digits, and then--e.g.--a root is expressed in them. But this expression in a sequence of digits only has significance through being the expression for a real number. If someone subsequently alters it, he has only succeeded in distorting the expression, but not in obtaining a new number.

224

Page 35

183 If ' $\sqrt{2}$ ' is anything at all, then it is the same as $\sqrt{2}$, only another expression for it; the expression in another system. It doesn't measure until it is in a system. You would no more say of ' $\sqrt{2}$ ' that it is a limit towards which the sums of a series are tending than you would of the instruction to throw dice.

225

Page 35

184 That we can apply the law holds also for the law to throw digits like dice. And what distinguishes π ' from this can only consist in our knowing that there must be a law governing the occurrences

Page Break 36

of the digit 7 in π , even if we don't yet know what the law is. π ' alludes to a law which is as yet unknown.

227

Page 36

185 Only a law approaches a value.

228

Page 36

186 The letter π stands for a law which has its position in arithmetical space. Whereas π ' doesn't use the idioms of arithmetic and so doesn't assign the law a place in this space. For substituting 3 for 7 surely adds absolutely nothing to the law and in this system isn't an arithmetical operation at all.

228

Page 36

187 To determine a real number a rule must be completely intelligible *in itself*. That is to say, it must not be essentially undecided whether a part of it could be dispensed with. If the extensions of two laws coincide as far as we've gone, and I cannot compare the laws as such, then the numbers defined cannot be compared.

Page 36

188 The expansion of π is simultaneously an expression of the nature of π and of the nature of the decimal system. Arithmetical operations only use the decimal system as a means to an end. They can be translated into the language of any other number system, and do not have any of them as their *subject matter*.--A general rule of operation gets its generality from the generality of the change it effects in the numbers. π ' makes the decimal system into its subject matter, and for that reason it is no longer sufficient that we can use the rule to form the extension. 231

Page 36

189 A law where p runs through the series of whole numbers except for those for which Fermat's last theorem doesn't hold. Would this law define a real number? The number F wants to use the spiral... and choose sections of this spiral according to a principle. But this principle doesn't belong to the spiral. There is admittedly a law there, but it doesn't refer directly to the number. The number is a sort of lawless by-product of the law.

232

Page Break 37

XVIII

Page 37

190 In this context we keep coming up against something that could be called an 'arithmetical experiment'. Thus the primes come out from the method for looking for them, as the results of an experiment. I can certainly see a law in the rule, but not in the numbers that result.

235

Page 37

191 A number must measure in and of itself. If it doesn't do that but leaves it to the rationals, we have no need of it.--The true expansion is the one which evokes from the law a comparison with a rational number.

235

Page 37

192 A real number can be compared with the fiction of an infinite spiral, whereas structures like F , P or π ' only with finite sections of a spiral.

237

Page 37

193 To compare rational numbers with $\sqrt{2}$, I have to square them.--They then assume the form \sqrt{a} , where \sqrt{a} is now an arithmetical operation. Written out in this system, they can be compared with $\sqrt{2}$, and it is for me as if the spiral of the irrational number had shrunk to a point.

237

Page 37

194 Is an arithmetical experiment still possible when a recursive definition has been set up? No, because with the recursion each stage becomes arithmetically comprehensible.

238

Page 37

195 Is it possible to prove a greater than b , without being able to prove at which place the difference will come to light? 1.4--Is that the square root of 2? No, it's the root of 1.96. That is, I can immediately write it down as an approximation to $\sqrt{2}$.

238

Page 37

196 If the real number is a rational number a , a comparison of its law with a must show this. That means the law must be so formed as to 'click into' the rational number when it comes to the

Page Break 38

appropriate place. It wouldn't do, e.g., if we couldn't be sure whether $\sqrt{25}$ really breaks off at 5.

240

Page 38

197 Can I call a spiral a number if it is one which, for all I know, comes to a stop at a rational point? There is a lack of a method for comparing with the rationals. Expanding indefinitely isn't a method, even when it leads to a result of the comparison.

241

Page 38

198 If the question how F compares with a rational number has no sense, since all expansion still hasn't given us an answer, then this question also had no sense before we tried to settle the matter at random by means of an extension.

242

Page 38

199 It isn't only necessary to be able to say whether a given rational number is the real number: we must also be able

to say how close it can possibly come to it. An order of magnitude for the distance apart. Decimal expansion doesn't give me this, since I cannot know e.g. how many 9s will follow a place that has been reached in the expansion.--'e isn't this number' means nothing; we have to say 'It is at least this interval away from it'.

243

Page 38

Appendix: From F. Waismann's shorthand notes of a conversation on 30 December 1930

245

XIX

Page 38

200 It appears to me that negation in arithmetic is interesting only in conjunction with a certain generality.--Indivisibility and inequality.--I don't write ' $\sim(5 \times 5 = 30)$ ', I write $5 \times 5 \neq 30$, since I'm not negating anything but want to establish a relation between 5×5 and 30 (and hence something positive). Similarly, when I exclude divisibility, this is equivalent to establishing indivisibility.

247

Page Break 39

Page 39

201 There is something recalcitrant to the application of the law of the excluded middle in mathematics--Looking for a law for the distribution of primes. We want to replace the negative criterion for a prime number by a positive one--but this negation isn't what it is in logic, but an indefiniteness.--The negation of an equation is as like and as unlike the denial of a proposition as the affirmation of an equation is as like or unlike the affirmation of a proposition.

248

Page 39

202 Where negation essentially--on logical grounds--corresponds to a disjunction or to the exclusion of one part of a logical series in favour of another--then here it must be one and the same as those logical forms and therefore only apparently a negation.

249

Page 39

203 Yet what is expressed by inequalities is *essentially* different from what is expressed by equations. And so you can't immediately compare a law yielding places of a decimal expansion which works with inequalities, with one that works with equations. Here we have completely different methods and consequently different kinds of arithmetical structure.

250

Page 39

204 Can you use the prime numbers to define an irrational number? As far as you can foresee the primes, and no further.

251

XX

Page 39

205 Can we say a patch is simpler than a larger one?--It seems as if it is impossible to see a uniformly coloured patch as composite.--The larger *geometrical* structure isn't composed of smaller *geometrical* structures. The 'pure geometrical figures' are of course only logical possibilities.

252

Page 39

206 Whether it makes sense to say 'This part of a red patch is red' depends on whether there is absolute position. It's possible to

Page Break 40

establish the identity of a position in the visual field, since we would otherwise be unable to distinguish whether a patch always stays in the same place. In visual space there is absolute position, absolute direction, and hence absolute motion. If this were not so, there would be *no sense* in speaking in this context of the same or different places. This shows the structure of our visual field: for the criterion for its structure is what propositions make sense for it.

253

Page 40

207 Can I say: 'The top half of my visual field is red'?--There isn't a relation of 'being situated' which would hold between a colour and a position.

257

Page 40

208 It seems to me that the concept of distance is given immediately in the structure of visual space. Measuring in visual space. Equal in length, unequal in parts. Can I be sure that what I count is really the number I see?

257

Page 40

209 But if I can't say there is a definite number of parts in a and b , how in that case am I to describe the visual

image?--'Blurred' and 'unclear' are relative expressions.--If we were really to see 24 and 25 parts in *a* and *b*, we couldn't then see *a* and *b* as equal. The word 'equal' has a meaning even for visual space which stamps this as a contradiction. 260

Page 40

210 The question is, how to explain certain contradictions that arise when we apply the methods of inference used in Euclidean space to visual space. This happens because we can only see the construction piecemeal and not as a whole: because there's no visual construction that could be composed of these individual visual pieces. 261

Page 40

211 The moment we try to apply exact concepts of measurement to immediate experience, we come up against a peculiar vagueness in this experience.--The words 'rough', 'approximate', etc. have

Page Break 41

only a relative sense, but they are still needed and they characterize the nature of our experience.--Problem of the heap of sand.--What corresponds in Euclidean geometry to the visual circle isn't a circle, but a class of figures.--Here it seems as though an exact *demarkation* of the inexactitude is impossible. We border off a swamp with a wall, and the wall is not *the* boundary of the swamp. 263

Page 41

212 The correlation between visual space and Euclidean space. *If* a circle is at all the sort of thing we see, then we must be able to see *it* and not merely something like it. If I cannot see an exact circle then in this sense neither can I see approximations to one. 265

Page 41

213 We need new concepts and we continually resort to those of the language of physical objects. For instance 'precision'. If it is right to say 'I do not see a sharp line', then a sharp line *is* conceivable. If it makes sense to say 'I never see an exact circle', then this implies: an exact circle is conceivable in visual space.--The word 'equal' used with quite different meanings.--Description of colour patches close to the boundary of the visual field. Clear that the lack of clarity is an internal property of visual space. 266

Page 41

214 What distinctions are there in visual space? The fact that you see a physical hundred-sided polygon as a circle implies nothing as to the *possibility* of seeing a hundred-sided polygon. Is there a *sense* in speaking of a visual hundred-sided polygon? 268

Page 41

215 Couldn't I say, 'Perhaps I see a perfect circle, but can never know it'? Only if it is established in what cases one calls one measurement more precise than another. It means nothing to say the circle is only an ideal to which reality can only approximate. But it may also be that we call an infinite possibility itself a circle. As with an irrational number.--Now, is the imprecision of measurement the same concept as the imprecision of visual images? Certainly not.--'Seems' and 'appears' ambiguous: in one

Page Break 42

case it is the result of measurement, in another a further appearance. 269

Page 42

216 'Sense datum' contains the idea: if we talk about 'the appearance of a tree' we are either taking for a tree something which is one, or something which is not. But this connection isn't there. 270

Page 42

217 *Can* you try to give 'the right model for visual space'? You cannot translate the blurredness of phenomena into an imprecision in the drawing. That visual space isn't Euclidean is already shown by the occurrence of two different kinds of lines and points. 271

XXI

Page 42

218 Simple colours--simple as psychological phenomena. I need a purely phenomenological colour theory in which mention is only made of what is actually perceptible and no hypothetical objects--waves, rods, cones and all that--occur. Can I find a metric for colours? Is there a sense in saying, e.g., that with respect to the amount of red in it, one colour is *halfway* between two other colours? 273

Page 42

219 Orange is a mixture of red and yellow in a sense in which yellow isn't a mixture of red and green although yellow comes between red and green in the colour circle.--If I imagine mixing a blue-green with a yellow-green I see straightaway that it can't happen, that a component part would first have to be 'killed'.

Page 42

220 I must know what in general is meant by the expression 'mixture of colours *A* and *B*'. If someone says to me that the colour of a patch lies between violet and red, I understand this and can imagine a redder violet than the one given. But: 'The colour lies

Page Break 43

between this violet and an orange'? The way in which the mixed colour lies between the others is no different here from the way red comes between blue and yellow.--'Red and yellow make orange' doesn't speak of a quantity of components. It means nothing to say this orange and this violet contain the same amount of red.--False comparison between the colour series and a system of two weights on a balance. 274

Page 43

221 The position here is just as it is with the geometry of visual space as compared with Euclidean geometry. There are here quantities of a different sort from that represented by our rational numbers.--If the expression 'lie between' on one occasion designates a mixture of two simple colours, and on another a simple component common to two mixed colours, the multiplicity of its application is different in the two cases.--You can also arrange all the shades along a straight line. But then you have to introduce rules to exclude certain transitions, and in the end the representation on the lines has to be given the same kind of topological structure as the octahedron has. Completely analogous to the relation of ordinary language to a 'logically purified' mode of expression. 276

Page 43

222 We can't say red has an orange tinge in the same sense as orange has a reddish tinge. '*x* is composed of *y* and *z*' and '*x* is the common component of *y* and *z*' are not interchangeable here. 278

Page 43

223 When we see dots of one colour intermingled with dots of another we seem to have a different sort of colour transition from that on the colour-circle. Not that we establish experimentally that certain colours arise in this way from others. For whether or not such a transition is *possible* (or conceivable) is an internal property of the colours. 279

Page 43

224 The danger of seeing things as simpler than they really are. Understanding a Gregorian mode means hearing something new; analogous with suddenly seeing 10 strokes, which I had hitherto only been able to see as twice five strokes, as a characteristic whole. 281

Page Break 44

XXII

Page 44

225 A proposition, an hypothesis, is coupled with reality--with varying degrees of freedom. All that matters is that the signs in the end still refer to immediate experience and not to an intermediary (a thing in itself). A proposition construed in such a way that it can be uncheckably true or false is completely detached from reality and no longer functions as a proposition. 282

Page 44

226 An hypothesis is a symbol for which certain rules of representation hold. The choice of representation is a process based on so-called induction (not mathematical induction). 283

Page 44

227 We only give up an hypothesis for an even higher gain. The question, how simple a representation is yielded by assuming a particular hypothesis, is connected with the question of probability. 284

Page 44

228 What is essential to an hypothesis is that it arouses an expectation, i.e., its confirmation is never completed. It has a different formal relation to reality from that of verification.--Belief in the uniformity of events. An hypothesis is a law for forming propositions. 285

Page 44

229 The probability of an hypothesis has its measure in how much evidence is needed to make it profitable to throw it out. If I say: I assume the sun will rise again tomorrow, because the opposite is so unlikely, I here mean by 'likely' and 'unlikely' something completely different from 'It's equally likely that I'll throw heads or tails'.--The expectation must make sense *now*; i.e. I must be able to compare it with how things stand at present. 286

Page 44

Page Break 45

world of material things compared with a phenomenological description.--Thus the theory of Relativity doesn't represent the logical multiplicity of the phenomena themselves, but that of the regularities observed. This multiplicity corresponds not to *one* verification, but to a *law* by verifications. 286

Page 45

231 Hypothesis and postulate. No conceivable experience can refute a postulate, even though it may be extremely inconvenient to hang on to it. Corresponding to the greater or slighter convenience, there is a greater or slighter probability of the postulate. It is senseless to talk of a measure for this probability. 288

Page 45

232 If I say 'That will probably occur', this proposition is neither verified by the occurrence nor falsified by its non-occurrence. If we argue about whether it is probable or not, we shall always adduce arguments from the past only.--It's always as if the same state of affairs could be corroborated by experience, whose existence was evident *a priori*. But that's nonsense. If the experience agrees with the computation, that means my computation is justified by the experience--not its *a priori* element, but its bases, which are *a posteriori*: certain natural laws. In the case of throwing a die the natural law takes the form that it is equally likely for any of the six sides to be the side uppermost. It's this law that we test. 289

Page 45

233 Certain possible events must contradict the law if it is to be one at all; and should these occur, they must be explained by a different law.--The prediction that there will be an equal distribution contains an assumption about those natural laws that I don't know precisely. 290

Page 45

234 A man throwing dice every day for a week throws nothing but ones--and not because of any defect in the die. Has he grounds

Page Break 46

for thinking that there's a natural law at work here which makes him throw nothing but ones?--When an insurance company is guided by probability, it isn't guided by the probability calculus but by a frequency actually observed. 291

Page 46

235 'Straight line with deviations' is only one form of description. If I state 'That's the rule', that only has a sense as long as I have determined the maximum number of exceptions I'll allow before knocking down the rule. 292

Page 46

236 It only makes sense to say of the stretch you actually see that it gives the general impression of a straight line, and not of an hypothetical one you assume. An experiment with dice can only give grounds for expecting things to go in the same way. 293

Page 46

237 Any 'reasonable' expectation is an expectation that a rule we have observed up to now will continue to hold. But the rule must have been observed and can't, for its part too, be merely expected.--Probability is concerned with the form and a standard of expectation. 294

Page 46

238 A ray of light strikes two different surfaces. The centre of each stretch seems to divide it into equally probable possibilities. This yields apparently incompatible probabilities. But the assumption of the probability of a certain event is verified by a frequency experiment; and, if confirmed, shows itself to be an hypothesis belonging to *physics*. The geometrical construction merely shows that the equal lengths of the sections was *no* ground for assuming equal likelihood. I can arbitrarily lay down a law, e.g. that if the lengths of the parts are equal, they are equally likely; but any other law is just as permissible. Similarly with further examples. It is from experience that we determine these possibilities as equally likely. But logic gives this stipulation no precedence. 295

PHILOSOPHICAL REMARKS

Page 49

Page Break 50

Page Break 51

I

Page 51

1 A proposition is completely logically analysed if its grammar is made completely clear: no matter what idiom it may be written or expressed in.

Page 51

I do not now have phenomenological language, or 'primary language' as I used to call it, in mind as my goal. I no longer hold it to be necessary. All that is possible and necessary is to separate what is essential from what is inessential in *our* language.

Page 51

That is, if we so to speak describe the class of languages which serve their purpose, then in so doing we have shown what is essential to them and given an immediate representation of immediate experience.

Page 51

Each time I say that, instead of such and such a representation, you could also use this other one, we take a further step towards the goal of grasping the essence of what is represented.

Page 51

A recognition of what is essential and what inessential in our language if it is to represent, a recognition of which parts of our language are wheels turning idly, amounts to the construction of a phenomenological language.

Page 51

Physics differs from phenomenology in that it is concerned to establish laws. Phenomenology only establishes the possibilities. Thus, phenomenology would be the grammar of the description of those facts on which physics builds its theories.

Page 51

To explain is more than to describe; but every explanation contains a description.

Page 51

An octahedron with the pure colours at the corner-points e.g. provides a *rough* representation of colour-space, and this is a grammatical representation, not a psychological one. On the other hand, to say that in such and such circumstances you can see a red

Page Break 52

after-image (say) is a matter of psychology. (*This* may, or may not, be the case--the other is *a priori*; we can establish the one by experiment but not the other.)

Page 52

Using the octahedron as a representation gives us a *bird's-eye view* of the grammatical rules [†1].

Page 52

The chief trouble with our grammar is that we don't have a *bird's-eye view* of it [†2].

Page 52

What Mach calls a thought experiment is of course not an experiment at all [†3]. At bottom it is a grammatical investigation.

Page 52

2 Why is philosophy so complicated? It ought, after all, to be *completely* simple. Philosophy unties the knots in our thinking, which we have tangled up in an absurd way; but to do that, it must make movements which are just as complicated as the knots. Although the *result* of philosophy is simple, its methods for arriving there cannot be so.

Page 52

The complexity of philosophy is not in its matter, but in our tangled understanding.

Page 52

3 How strange if logic were concerned with an 'ideal' language and not with *ours*. For what would this ideal language express? Presumably, what we now express in our ordinary language; in that case, this is the language logic must investigate. Or something else: but in that case how would I have any idea what that would be?--Logical analysis is the analysis of something we have, not of something we don't have. Therefore it is the analysis of propositions *as they stand*. (It would be odd if the human race had been speaking all this time without ever putting together a genuine proposition.)

Page 52

When a child learns 'Blue is a colour, red is a colour, green, yellow--all are colours', it learns nothing new about the colours,

Page Break 53

but the meaning of a variable in such propositions as: 'There are beautiful colours in that picture' etc. The first proposition tells him the values of a variable.

Page 53

The words 'Colour', 'Sound', 'Number' etc. could appear in the chapter headings of our grammar. They need not occur within the chapters but that is where their structure is given.

Page 53

4 Isn't the theory of harmony at least in part phenomenology and therefore grammar?

Page 53

The theory of harmony isn't a matter of taste.

Page 53

If I could describe the point of grammatical conventions by saying they are made necessary by certain properties of the colours (say), then that would make the conventions superfluous, since in that case I would be able to say precisely that which the conventions exclude my saying. Conversely, if the conventions were necessary, i.e. if certain combinations of words had to be excluded as nonsensical, then for that very reason I cannot cite a property of colours that makes the conventions necessary, since it would then be conceivable that the colours should not have this property, and I could only express that by violating the conventions.

Page 53

It cannot be proved that it is nonsense to say of a colour that it is a semitone higher than another. I can only say 'If anyone uses words with the meanings that I do, then he can connect no sense with this combination. If it makes sense to him, he must understand something different by these words from what I do.'

Page 53

5 The arbitrariness of linguistic expressions: might we say: A child must of course learn to speak a particular language, but doesn't have to learn to think, i.e. it would think spontaneously, even without learning any language?

Page 53

But in my view, if it thinks, then it forms for itself pictures and in a certain sense these are arbitrary, that is to say, in so far as other

Page Break 54

pictures could have played the same role. On the other hand, language has certainly also come about naturally, i.e. there must presumably have been a first man who for the first time expressed a definite thought in spoken words. And besides, the whole question is a matter of indifference because a child learning a language only learns it by beginning to think in it. Suddenly beginning; I mean: there is no preliminary stage in which a child already uses a language, so to speak uses it for communication, but does not yet think in it.

Page 54

Of course, the thought processes of an ordinary man consist of a medley of symbols, of which the strictly linguistic perhaps form only a small part.

Page 54

6 If I explain the meaning of a word 'A' to someone by pointing to something and saying 'This is A', then this expression may be meant in two different ways. Either it is itself a proposition already, in which case it can only be

understood once the meaning of 'A' is known, i.e. I must now leave it to chance whether he takes it as I meant it or not. Or the sentence is a definition. Suppose I have said to someone 'A is ill', but he doesn't know who I mean by 'A', and I now point at a man, saying 'This is A'. Here the expression is a definition, but this can only be understood if he has already gathered what kind of object it is through his understanding of the grammar of the proposition 'A is ill'. But this means that any kind of explanation of a language presupposes a language already. And in a certain sense, the use of language is something that cannot be taught, i.e. I cannot use language to teach it in the way in which language could be used to teach someone to play the piano.--And that of course is just another way of saying: I cannot use language to get outside language.

Page 54

7 Grammar is a 'theory of logical types'.

Page Break 55

Page 55

I do not call a rule of representation a convention if it can be justified in propositions: propositions describing what is represented and showing that the representation is adequate. Grammatical conventions cannot be justified by describing what is represented. Any such description already presupposes the grammatical rules. That is to say, if anything is to count as nonsense in the grammar which is to be justified, then it cannot at the same time pass for sense in the grammar of the propositions that justify it (etc.).

Page 55

You cannot use language to go beyond the possibility of evidence.

Page 55

The possibility of explaining these things always depends on someone else using language in the same way as I do. If he states that a certain string of words makes sense to him, and it makes none to me, I can only suppose that in this context he is using words with a different meaning from the one I give them, or else is speaking without thinking.

Page 55

8 Can anyone believe it makes sense to say 'That's not a noise, it's a colour'?

Page 55

On the other hand, you can of course say 'It's not the noise but the colour that makes me nervous', and here it might look as if a variable assumed a colour and a noise as values. ('Sounds and colours can be used as vehicles of communication.') It is clear that this proposition is of the same kind as 'If you hear a shot or see me wave, run.' For this is the kind of co-ordination on the basis of which a heard or seen language functions.

Page 55

9 Asked whether philosophers have hitherto spoken nonsense, you could reply: no, they have only failed to notice that they are using a word in quite different senses. In this sense, if we say it's nonsense to say that one thing is as identical as another, this needs qualification, since if anyone says this with conviction, then at that

Page Break 56

moment he means something by the word 'identical' (perhaps 'large'), but isn't aware that he is using the word here with a different meaning from that in $2 + 2 = 4$.

Page Break 57

II

Page 57

10 If you think of propositions as instructions for making models, their pictorial nature becomes even clearer.

Page 57

Since, for it to be possible for an expression to guide my hand, it *must* have the same multiplicity as the action desired.

Page 57

And this must also explain the nature of negative propositions. Thus, for example, someone might show his understanding of the proposition 'The book is not red' by throwing away the red when preparing a model.

Page 57

This and the like would also show in what way the negative proposition has the multiplicity of the proposition it denies and *not* of those propositions which could perhaps be true in its stead.

Page 57

11 What does it mean to say 'Admittedly I can't see any red, but if you give me a paint-box, I can point it out to you'? How can you *know* that you will be able to point it out if...; and so, that you will be able to recognize it when

you see it?

Page 57

This might mean two different kinds of things: it might express the expectation that I shall recognize it if I am shown it, in the same sense that I expect a headache if I'm hit on the head; then it is, so to speak, an expectation that belongs to physics, with the same sort of grounds as any other expectation relating to the occurrence of a physical event.--Or else it has nothing to do with expecting a physical event, and for that reason neither would my proposition be falsified if such an event should fail to occur. Instead, it's as if the proposition is saying that I possess a paradigm that I could at any time compare the colour with. (And the 'could' here is logical possibility.)

Page 57

Taking the first interpretation: if, on looking at a certain colour, I in fact do give a sign of recognition, how do I know it is the colour that I *meant*?

Page Break 58

Page 58

The propositions of our grammar are always of the same sort as propositions of physics and not of the same sort as the 'primary' propositions which treat of what is immediate.

Page 58

12 The idea that you 'imagine' the meaning of a word when you hear or read it, is a naive conception of the meaning of a word. And in fact such imagining gives rise to the same question as a word meaning something. For if, e.g., you imagine sky-blue and are to use this image as a basis for recognizing or looking for the colour, we are still forced to say that the image of the colour isn't the same as the colour that is really seen; and in that case, how can one compare these two?

Page 58

Yet the naive theory of *forming-an-image* can't be utterly wrong.

Page 58

If we say 'A word only has meaning in the context of a proposition', then that means that it's only in a proposition that it functions as a word, and this is no more something that can be said than that an armchair only serves its purpose when it is in space. Or perhaps better: that a cogwheel only functions as such when engaged with other cogs.

Page 58

13 Language must have the same multiplicity as a control panel that sets off the actions corresponding to its propositions.

Page 58

Strangely enough, the problem of *understanding* language is connected with the problem of the Will.

Page 58

Understanding a command before you obey it has an affinity with willing an action before you perform it.

Page 58

Just as the handles in a control room are used to do a wide variety of things, so are the words of language that correspond to the handles. One is the handle of a crank and can be adjusted continuously; one belongs to a switch and is always either on or

Page Break 59

off; a third to a switch which permits three or more positions; a fourth is the handle of a pump and only works when it is being moved up and down, etc.; but all are handles, are worked by hand.

Page 59

14 A word only has meaning in the context of a proposition: that is like saying only in use is a rod a lever. Only the application makes it into a lever.

Page 59

Every instruction can be construed as a description, every description as an instruction.

Page 59

15 What does it mean, to understand a proposition as a member of a system of propositions? (It's as if I were to say: the use of a word isn't over in an instant, any more than that of a lever).

Page 59

Imagine a gearbox whose lever can take four positions. Now of course it can only take these positions in succession, and that takes time; and suppose it happened that it only ever occupied one of these positions, since the gearbox was then destroyed. Wasn't it still a gearbox with *four* positions? Weren't the four possible?

Page 59

Anyone who saw it would have seen its complexity, and its complexity is only to be explained by the use for which it was intended, to which in fact it was not put. Similarly I would like to say in the case of language: What's the point of all these preparations; they only have any meaning if they find a use.

Page 59

You might say: The sense of a proposition is its purpose. (Or, of a word 'Its meaning is its purpose'.)

Page 59

But the natural history of the use of a word can't be any concern of logic.

Page 59

16 If I expect an event and that which fulfils my expectation occurs, does it then make sense to ask whether that really is the

Page Break 60

event I expected? i.e. how would a proposition that asserted this be verified? It is clear that the *only* source of knowledge I have here is a comparison of the *expression* of my expectation with the event that has occurred.

Page 60

How do I know that the colour of this paper, which I call 'white', is the same as the one I saw here yesterday? By recognizing it again; and recognizing it again is my only source of knowledge here. In that case, 'That it is the same' *means* that I recognize it again.

Page 60

Then of course you also can't ask whether it really is the same and whether I might not perhaps be mistaken; (whether it *is* the same and doesn't just *seem* to be.)

Page 60

Of course, it would also be possible to say that the colour is the same because chemical investigations do not disclose any change. So that if it doesn't look the same to me then I am mistaken. But even then there must still be something that is immediately recognized.

Page 60

And the 'colour' I can recognize immediately and the one I establish by chemical investigation are two different things.

Page 60

One source only yields *one* thing.

Page 60

17 Is it an objection to my view that we often speak half or even entirely automatically? If someone asks me 'Is the curtain in this room green?' and I look and say, 'No, red', I certainly don't have to hallucinate green and compare it with the curtain. No, just looking at the curtain can automatically produce the answer, and yet this answer is of interest to Logic, whereas a whistle, say, that I make automatically on seeing red is not. Isn't the point that Logic is only interested in this answer as a part of a language system? The system our books are written in. Could we say Logic considers language *in extenso*? And so, in the same way as grammar.

Page 60

Could you say that Logic has nothing to do with that utterance if it was merely automatic? For should Logic bother itself with the question whether the proposition was also really thoroughly

Page Break 61

thought? And what would the criterion for that be? Surely not the lively play of images accompanying its expression I It is plain that here we have got into a region that is absolutely no concern of ours and from which we should retire with the utmost alacrity.

Page 61

18 Here we come to the apparently trivial question, what does Logic understand by a word--is it an ink-mark, a sequence of sounds, is it necessary that someone should associate a sense with it, or should have associated one, etc., etc.?--And here, the crudest conception must obviously be the only correct one.

Page 61

And so I will again talk about 'books'; here we have words; if a mark should happen to occur that looks like a word, I say: that's not a word, it only looks like one, it's obviously unintentional. This can only be dealt with from the standpoint of normal common sense. (It's extraordinary that that in itself constitutes a change in perspective.)

Page 61

I do not believe that Logic can talk about sentences [\dagger 1] in any other than the normal sense in which we say, 'There's a sentence written here' or 'No, that only looks like a sentence, but isn't', etc., etc.

Page 61

The question 'What is a word?' is completely analogous with the question 'What is a chessman?'

Page 61

19 Isn't it agreement and disagreement that is primary, just as recognition is what is primary and identity what is secondary? If we see a proposition verified, what higher court is there to which we could yet appeal in order to tell whether it *really* is true?

Page 61

The agreement of a proposition with reality only resembles the agreement of a picture with what it depicts to the same extent as the agreement of a memory image with the present object.

Page Break 62

Page 62

But we can look at recognition, like memory, in two different ways: as a source of the concepts of the past and of identity, or as a way of checking what happened in the past, and on identity.

Page 62

If I can see two patches of colour alongside one another and say that they have the same colour, and if I say that this patch has the same colour as one I saw earlier, the identity assertion means something different in the two cases, since it is differently verified.

Page 62

To know that it *was* the same colour is something different from knowing that it *is* the same colour.

Page Break 63

III

Page 63

20 You can draw a plan from a description. You can translate a description into a plan.

Page 63

The rules of translation here are not essentially different from the rules for translating from one verbal language into another.

Page 63

A wrong conception of the way language functions destroys, of course, the *whole* of logic and everything that goes with it, and doesn't just create some merely local disturbance.

Page 63

If you exclude the element of intention from language, its whole function then collapses.

Page 63

21 What is essential to intention is the picture: the picture of what is intended.

Page 63

It may look as if, in introducing intention, we were introducing an uncheckable, a so-to-speak metaphysical element into our discussion. But the essential difference between the picture conception and the conception of Russell, Ogden and Richards, is that it regards recognition as seeing an internal relation, whereas in their view this is an external relation.

Page 63

That is to say, for me, there are only two things involved in the fact that a thought is true, i.e. the thought and the fact; whereas for Russell, there are three, i.e. thought, fact and a third event which, if it occurs, is just recognition. This third event, a sort of satisfaction of hunger (the other two being hunger and eating a particular kind of food), could, for example, be a feeling of pleasure. It's a matter of complete indifference here how we describe this third event; that is irrelevant to the essence of the theory.

Page Break 64

Page 64

The causal connection between speech and action is an external relation, whereas we need an internal one.

Page 64

22 I believe Russell's theory amounts to the following: if I give someone an order and I am happy with what he then does, then he has carried out my order.

Page 64

(If I wanted to eat an apple, and someone punched me in the stomach, taking away my appetite, then it was this punch that I originally wanted.)

Page 64

The difficulty here in giving an account of what's going on is that if someone makes false assumptions about the way language works and tries to give an account of something with language conceived as functioning in this way, the result is not something false but nonsense.

Page 64

Thus in terms of Russell's theory I could not express things by saying that the order is carried out *if* I am made happy by what happens, because I have also to recognise my being made happy, and this requires that something *else* should happen which I cannot describe in advance.

Page 64

23 Suppose you were now to say: pictures do occur, but they are not what is regular; but how strange then, if they happen to be there and a conflict were now to arise between the two criteria of truth and falsity. How should it be adjudicated?

Page 64

In that case, there would, of course, be no distinction between a command and its countermand, since both could be obeyed in the same way.

Page 64

If when a language is first learnt, speech, as it were, is connected up to action--i.e. the levers to the machine--then the question arises, can these connections possibly break down? If they can't, then I have to accept any action as the right one; on the other hand if they can, what criterion have I for their having broken down? For what means have I for *comparing* the original arrangement with the subsequent action?

Page Break 65

Page 65

It is such *comparison* which is left out in Russell's theory. And comparison doesn't consist in confronting the representation with what it represents and through this confrontation experiencing a phenomenon, which, as I have said, itself could not be described in advance.

Page 65

(Experience decides whether a proposition is true or false, but not its sense.)

Page 65

24 How is a picture meant? The intention never resides in the picture itself, since, no matter how the picture is formed, it can always be meant in different ways. But that doesn't mean that the way the picture is meant only emerges when it elicits a certain reaction, for the intention is already expressed in the way I *now* compare the picture with reality.

Page 65

In philosophy we are always in danger of giving a mythology of the symbolism, or of psychology: instead of simply saying what everyone knows and must admit.

Page 65

What if someone played chess and, when he was mated, said, 'Look, I've won, for *that* is the goal I was aiming at'? We would say that such a man simply wasn't trying to play chess, but another game; whereas Russell would have to say that if anyone plays with the pieces and is satisfied with the outcome, then he has won at chess.

Page 65

I expect that the rod will be 2 m high *in the same sense* in which it is now 1 m 99 cm high.

Page 65

25 The fulfilment of an expectation doesn't consist in a third thing happening which you could also describe in another way than just as 'the fulfilment of the expectation', thus for example as a feeling of satisfaction or pleasure or whatever.

Page 65

For expecting that *p* will be the case must be the same as expecting that this expectation will be fulfilled; whereas, if I am wrong,

Page Break 66

expecting *p* would be different from expecting that this expectation will be fulfilled.

Page 66

Isn't it like this: My theory is completely expressed in the fact that the state of affairs satisfying the expectation of *p* is represented by the proposition *p*? And so, not by the description of a *totally* different event.

Page 66

26 I should like to say, if there were only an external connection no connection could be described at all, since we only describe the external connection by means of the internal one. If this is lacking, we lose the footing we need for

describing anything at all--just as we can't shift anything with our hands unless our feet are planted firmly.

Page 66

Causality rests on an observed uniformity. Now, that doesn't mean that a uniformity we have observed until now will go on for ever, but it must be an established fact that events have been uniform until now; *that* cannot in turn be the insecure result of a series of observations which again is itself not a datum, but depends on another equally insecure series, etc. *ad inf.*

Page 66

If I wish that *p* were the case, then of course *p* is not the case and there must be a surrogate for *p* in the state of wishing, just as, of course, in the expression of the wish.

Page 66

There's nothing left for me, in answer to the question, 'What does *p* instruct you to do?', but to say it, i.e. to give another sign.

Page 66

But can't you give someone an instruction by showing him how to do something? Certainly: and then you have to tell him 'Now copy that'. Perhaps you have already had examples of this before but now you have to say to him that what happened then should happen now. That still means: sooner or later there is a leap from the sign to what is signified.

Page 66

27 The meaning of a question is the method of answering it: then what is the meaning of 'Do two men really mean the same by the word "white"?'

Page Break 67

Page 67

Tell me *how* you are searching, and I will tell you *what* you are searching for.

Page 67

If I understand an order but do not carry it out, then understanding it can only consist in a process which is a *surrogate* for its execution, and so in a *different* process from its execution.

Page 67

I should like to say, assuming the surrogate process to be a picture doesn't get me anywhere, since even that does not do away with the transition from the picture to what is depicted.

Page 67

If you were to ask: 'Do I expect the future itself, or only something similar to the future?', that would be nonsense. Or, if you said, 'We can never be certain that *that* was what we really expected.'

Page 67

Co-ordinating signals always contains something general, otherwise the coordination is unnecessary. It is a co-ordination which has to be understood in the particular case.

Page 67

If I say to someone that it will be fine *tomorrow*, he gives evidence of his having understood by not trying to verify the proposition *now*.

Page 67

28 Expecting is connected with looking for: looking for something presupposes that I know what I am looking for, without what I am looking for having to exist.

Page 67

Earlier I would have put this by saying that searching presupposes the elements of the complex, but not *the* combination that I was looking for.

Page 67

And that isn't a bad image: for, in the case of language, that would be expressed by saying that the sense of a proposition only presupposes the grammatically correct use of certain words.

Page 67

How do I know that I have found *that* which I was looking for? (That what I expected has occurred, etc.)

Page 67

I cannot confront the previous expectation with what happens.

Page 67

The event that replaces the expectation, is a reply to it.

Page Break 68

Page 68

But for that to be so, necessarily *some* event must take its place, and that of course implies that the expectation must be in the same space as what is expected.

Page 68

In this context I am talking about an expectation only as something that is necessarily either fulfilled or disappointed: therefore not of an expectation in the void.

Page 68

29 The event which takes the place of an expectation, answers it: i.e. the replacement constitutes the answer, so that no question can arise whether it really is the answer. Such a question would mean putting the *sense* of a proposition in question. 'I expect to see a red patch' describes, let's say, *my present mental state*. 'I see a red patch' describes what I expect: a completely different event from the first. Couldn't you now ask whether the word 'red' has a different meaning in the two cases? Doesn't it look as if the first proposition uses an alien and inessential event to describe my mental state? Perhaps like this: I now find myself in a state of expectation which I characterize by saying that it is satisfied by the event of my seeing a red patch. That is, as though I were to say 'I am hungry and know from experience that eating a particular kind of food will or would satisfy my hunger.' But expectation isn't like that! Expectation is not given an external description by citing what is expected, as is hunger by citing what food satisfies it--in the last resort the appropriate food of course can still only be a matter of conjecture. No, describing an expectation by means of what is expected is giving an internal description.

Page 68

The way the word 'red' is used is *such that* it has a use in all these propositions: 'I expect to see a red patch', 'I remember a red patch', 'I am afraid of a red patch', etc.

Page 68

30 If I say 'This is the same event as I expected', and 'This is the same event as also happened on that occasion', then the word

Page Break 69

'same' has two different meanings. (And you wouldn't normally say 'This is the same as I expected' but 'This is what I expected'.)

Page 69

Could we imagine any language at all in which expecting p was described without using ' p '?

Page 69

Isn't that *just as* impossible as a language in which $\sim p$ would be expressed without using ' p '?

Page 69

Isn't this simply because *expectation* uses the same symbol as the thought of its fulfilment?

Page 69

For if we think in signs, then we also expect and wish in signs.

Page 69

(And you could almost say that someone could hope in German and fear in English, or vice versa.)

Page 69

31 Another mental process belonging to this group, and which ties in with all these things, is *intention*. You could say that language is like a control room operated with a particular *intention* or built for a particular purpose.

Page 69

If a mechanism is *meant* to act as a brake, but for some reason accelerates a machine then the purpose of the mechanism cannot be found out from it alone.

Page 69

If you were then to say 'That's a brake lever but it doesn't work', you would be talking about intention. It is just the same as when we still call a broken clock a clock.

Page 69

(Psychological--trivial--discussions of expectation, association, etc. always leave out what is really remarkable, and you notice that they talk all around, without touching on the vital point.)

Page 69

32 I only use the terms the expectation, thought, wish, etc., that p will be the case, for processes having the multiplicity that finds

Page Break 70

expression in p , and thus only if they are *articulated*. But in that case they are what I call the interpretation of signs.

Page 70

I only call an *articulated* process a thought: you could therefore say 'only what has an articulated

expression'.

Page 70

(Salivation--no matter how precisely measured--is *not* what I call expecting.)

Page 70

Perhaps we have to say that the phrase 'interpretation of signs' is misleading and instead we ought to say 'the use of signs'. For 'interpretation' makes it sound as if one were now to correlate the word 'red' with the colour (when it isn't even there), etc. And now the question again arises: what is the connection between sign and world? Could I look for something unless the space were there to look for it in?

Page 70

Where does the sign link up with the world?

Page 70

33 To look for something is, surely, an expression of expectation. In other words: How you search in one way or another expresses what you expect.

Page 70

Thus the idea would be: what expectation has in common with reality is that it refers to another point in the *same* space. ('Space' in a completely general sense.)

Page 70

I see a patch getting nearer and nearer to the place where I expect it.

Page 70

If I say I remember a colour--say, the colour of a certain book--you could take as evidence for this the fact that I was in a position to mix this colour or recognize it again, or say of other colours that they are more like or less like the colour I remember.

Page 70

Expectation, so to speak, prepares a yardstick for measuring the event when it comes and what's more, in such a way that it will necessarily be possible to measure the one with the other, whether the event coincides with the expected graduation mark or not.

Page 70

It is, say, as if I guess a man's height by looking at him, saying

Page Break 71

'I believe he's 5 ft 8 in' and then set about measuring him with a tape measure. Even if I don't know how tall he is, I still know that his height is measured with a tape measure and not a weighing machine.

Page 71

If I expect to see red, then I *prepare* myself for red.

Page 71

I can prepare a box for a piece of wood to fit in, just because the wood, whatever it's like, must have a volume.

Page 71

If there were no connection between the act of expectation and reality, you could expect a nonsense.

Page 71

34 The expectation of p and the occurrence of p correspond perhaps to the hollow shape of a body and the solid shape. Here p corresponds to the shape of the volume, and the different ways in which this shape is given correspond to the distinction between expectation and occurrence.

Page 71

If I say 'I can make you a sketch of that any time you like', then that presupposes that I *am* in the same space as the business involved.

Page 71

Our expectation anticipates the event. In this sense, it makes a model of the event. But we can only make a model of a fact in *the* world we live in, i.e. the model must be essentially related to the world we live in and what's more, independently of whether it's true or false.

Page 71

If I say that the representation must treat of my world, then you cannot say 'since otherwise I could not verify it', but 'since otherwise it wouldn't even begin to make sense to me'.

Page 71

35 In expecting, the part corresponding to searching in a space is the directing of one's attention.

Page Break 72

Page 72

Surely the strange thing about expectation is that we know that it is an *expectation*. For we couldn't, e.g., imagine the following situation: I have some image or other before me and say: 'Now, I don't know whether it's an expectation or a memory, or an image without any relation to reality.'

Page 72

And *that* is what shows that expectation is immediately connected with reality.

Page 72

For of course you couldn't say that the future the expectation speaks of--I mean the concept of the future--was also only a surrogate for the real future.

Page 72

For I await in just as real a sense as I *wait*.

Page 72

Could you also say: You cannot describe an expectation unless you can describe the present reality; or, you cannot describe an expectation unless you can give a description *comparing* the expectation with the present, of the form: Now I see a red circle *here*, and expect a blue square *there later on*.

Page 72

That is to say the yardstick of language must be applied at the point which is present and then points out beyond it--roughly speaking, in the direction of the expectation.

Page 72

36 It only makes sense to give the length of an object if I have a method for finding the object--since otherwise I cannot apply a yardstick to it.

Page 72

What I once called 'objects', simples, were simply what I could refer to without running the risk of their possible non-existence; i.e. that for which there is neither existence nor non-existence, and that means: what we can speak about *no matter what may be the case*.

Page 72

The visual table is not composed of electrons.

Page 72

What if someone said to me 'I expect three knocks on the door' and I replied 'How do you know *three knocks* exist?'--Wouldn't that be just like the question 'How do you know six feet exist?' after someone has said 'I believe A is 6 feet high'?

Page Break 73

Page 73

37 Can absolute silence be confused with inner deafness, meaning having no acquaintance with the concept of sound? If that were so, you couldn't distinguish lacking the sense of hearing from lacking any other sense.

Page 73

But isn't this exactly the same question as: 'Is a man who cannot see any red around him at present, in the same position as someone incapable of seeing red?'

Page 73

You could of course say: The one can still imagine red, but the red we imagine is not the same as the red we see.

Page 73

38 Our ordinary language has no means for describing a particular shade of a colour, such as the brown of my table. Thus it is incapable of producing a picture of this colour.

Page 73

If I want to tell someone what colour some material is to be, I send him a sample, and obviously this sample belongs to language; and equally the memory or image of a colour that I conjure by a word, belongs to language.

Page 73

The memory and the reality must be in *one* space.

Page 73

I could also say: the image and the reality are in *one* space.

Page 73

If I compare two colour samples in front of me with one another, and if I compare a colour sample with my image of a sample, that is similar to comparing, on the one hand, the lengths of two rods standing up against each other and on the other of two that are apart. In that case, I can say perhaps, they are the same height, if, turning my gaze horizontally, I can glance from the tip of the one to the tip of the other.

As a matter of fact I have never seen a black patch become gradually lighter and lighter until it is white and then redden until it is red; but I know that this would be possible because I can imagine it; i.e. I operate with my images in colour space and do with them what would be possible with the colours. And my words

take their sense from the fact that they more or less completely reflect the operations of the images perhaps in the way in which a score can be used to describe a piece of music that has been played, but for example, does *not* reproduce the emphasis on each individual note.

Grammar gives language the necessary degrees of freedom.

IV

39 The colour octahedron is grammar, since it says that you can speak of a reddish blue but not of a reddish green, etc.

If I can only see something black and say it isn't red, how do I know that I am not talking nonsense, i.e. that it could be red, that there is red? Unless red is just another graduation mark on the same scale as black. What is the difference between 'That is not red' and 'That is not abracadabra'? Obviously I need to know that 'black', which describes the actual state of affairs (or is used in describing it), is that in whose place 'red' stands in the description.

But what does that mean? How do I know it isn't 'soft' in whose place 'red' stands? Can you say red is less different from black than from soft? That would of course be nonsense.

40 How far can you compare the colours with points on a scale?

Can you say that the direction leading from black to red is a different one from the one you must take from black to blue?

For, if there is black in front of me and I am expecting red, that's different from having black in front of me and expecting blue. And if there is a valid comparison with a ruler, the word 'blue' must so to speak give me the direction in which I go from black to blue; so to speak the method by which I reach blue.

Couldn't we also say: 'The proposition must give a construction for the position of blue, the point the fact must reach if such and such is to be blue'?

The fact that I can say that one colour comes closer to what I expected than another belongs here.

But how do these different directions find expression in grammar? Isn't it the same case as my seeing a grey and saying 'I expect this grey to go darker'? How does grammar deal with the distinction between 'lighter' and 'darker'? Or, how can the ruler going from white to black be applied to grey in a particular direction?

It's still as if grey were only *one* point; and how can I see the two *directions* in that? And yet I should be able to do so somehow or other if it is to be possible for me to get to a particular place in these directions [+1].

41 The feeling is as if, for it to negate p , $\sim p$ has in a certain sense first to make it true. One asks 'What isn't the case?' This must be represented but cannot be represented in such a way that p is actually made true.

A man with red/green colour blindness has a different colour system from a normal man. He will be like a man whose head was fixed in one position and so had a different kind of space, since for him there would only be visual space and therefore, e.g., no 'behind'. That wouldn't of course mean that Euclidean space was bounded for him. But that--at least as far as seeing things was concerned--he wouldn't acquire the concept of Euclidean space. Is the question then: can someone who doesn't know what red and green are like, really see what we (or I) call 'blue'?

and 'yellow'?

Page 76

This question must, of course, be just as nonsensical as the question whether someone else with normal vision really sees the same as I do.

Page 76

42 Grey must already be conceived as being in lighter/darker space if I want to talk of its being possible for it to get darker or lighter.

Page 76

So you might perhaps also say: the yardstick must already be applied, I cannot apply it how I like; I can only pick out a point on it.

Page 76

This amounts to saying: if I am surrounded by absolute silence,

Page Break 77

I cannot join (construct) or not join auditory space on to this silence as I like, i.e. either it is for me 'silence' as opposed to a sound, or the word 'silence' has no meaning for me, i.e. I cannot *choose* between inner hearing and *inner* deafness.

Page 77

And in just the same way, I cannot while I am seeing greyness *choose* between normal inner vision and partial or complete colour-blindness.

Page 77

Suppose we had a device for completely cutting out our visual activity so that we could lose our sense of sight; and suppose I had so cut it out: could I say in such circumstances 'I can see a yellow patch on a red background'? Could this way of talking make *sense* to me?

Page 77

43 I should like to say: for any question there is always a corresponding *method* of finding.

Page 77

Or you might say, a question *denotes* a method of searching.

Page 77

You can only search in a *space*. For only in space do you stand in a relation to where you are not.

Page 77

To understand the sense of a proposition means to know how the issue of its truth or falsity is to be decided.

Page 77

The essence of what we call the will is immediately connected with the continuity of the given.

Page 77

You must find the way from where you are to where the issue is decided.

Page 77

You cannot search wrongly; you *cannot* look for a visual impression with your sense of touch.

Page 77

You cannot compare a picture with reality, unless you can set it against it as a yardstick.

Page 77

You must be able to fit the proposition on to reality.

Page Break 78

Page 78

The reality that is perceived takes the place of the picture.

Page 78

If I am to settle whether two points are a certain distance apart, I must look at the distance that *does* separate them.

Page 78

44 How is a 'formally certified proposition' possible? It would be a proposition that you could tell was true or false by looking at it. But how can you discover by inspecting the proposition or thought that it is true? The thought is surely something quite different from the state of affairs asserted by the proposition.

Page 78

The method of taking measurements, e.g. spatial measurements, is related to a particular measurement in precisely the same way as the sense of a proposition is to its truth or falsity.

Page 78

The use, the application, of a yardstick doesn't presuppose any particular length for the object to be measured.

Page 78

That is why I can learn how to measure in general, without measuring *every* measurable object. (This isn't simply an analogy, but is in fact an example.)

Page 78

All that I need is: I must be able to be certain I can apply my yardstick.

Page 78

Thus if I say 'Three more steps and I'll see red', that presupposes that at any rate I can apply the yardsticks of length and colour.

Page 78

Someone may object that a scale with a particular height marked on it can say that something has that height, but not *what* has it.

Page 78

I would then perhaps reply that all I can do is say that something 3 m away from me in a certain direction is 2 m high.

Page 78

45 I will count any fact whose obtaining is a presupposition of a proposition's making sense, as belonging *to language*.

Page 78

It's easy to understand that a ruler is and must be in the same space as the object measured by it. But in what sense are *words* in

Page Break 79

the same space as an object whose length is described in words, or, in the same space as a colour, etc.? It sounds absurd.

Page 79

A black colour can become lighter but not louder. That means that it is in light/dark space but not loud/soft space.--But surely the object just stops being black when it becomes lighter. But in that case it was black and just as I can see movement (in the ordinary sense), I can see a colour movement.

Page 79

The unit length is part of the symbolism. It belongs to the method of projection. Its length is arbitrary, but *it* is what contains the specifically spatial element.

Page 79

And so if I call a length '3', the 3 signifies via the unit length presupposed in the symbolism.

Page 79

You can also apply these remarks to time.

Page 79

46 When I built language up by using a coordinate system for representing a state of affairs in space, I introduced into language an element which it doesn't normally use. This device is surely permissible. And it shows the connection between language and reality. The written sign without the coordinate system is senseless. Mustn't we then use something similar for representing colours?

Page 79

If I say something is three feet long, then that presupposes that somehow or other I am given the foot length. In fact it is given by a description: in such and such a place there is a rod one foot long. The 'such and such a place' indirectly describes a method for getting there; otherwise the specification is senseless. The place name 'London' only has a sense if it is possible to *try to find* London.

Page 79

A command is only then complete, when it makes sense no matter what may be the case. We might also say: That is when it is completely analysed.

Page Break 80

Page 80

47 That it doesn't strike us at all when we look around us, move about in space, feel our own bodies, etc., etc., shows how natural these things are to us. We do not notice that we see space perspectively or that our visual field is in

some sense blurred towards the edges. It doesn't strike us and never can strike us because it is *the* way we perceive. We never give it a thought and it's impossible we should, since there is nothing that contrasts with the form of our world.

Page 80

What I wanted to say is it's strange that those who ascribe reality only to things and not to our ideas [†1] move about so unquestioningly in the world as idea [†1] and never long to escape from it.

Page 80

In other words, how much of a matter of course the given is. It would be the very devil if this were a tiny picture taken from an oblique, distorting angle.

Page 80

This which we take as a matter of course, *life*, is supposed to be something accidental, subordinate; while something that normally never comes into my head, reality!

Page 80

That is, what we neither can nor want to go beyond would not be the world.

Page 80

Time and again the attempt is made to use language to limit the world and set it in relief--but it can't be done. The self-evidence of the world expresses itself in the very fact that language can and does only refer to it.

Page 80

For since language only derives the way in which it means from its meaning, from the world, no language is conceivable which does not represent this world.

Page 80

48 If the world of data is timeless, how can we speak of it at all?

Page Break 81

Page 81

The stream of life, or the stream of the world, flows on and our propositions are so to speak verified only at instants.

Page 81

Our propositions are only verified by the present.

Page 81

So they must be so constructed that they can be verified by it. And so in some way they must be commensurable with the present; and they cannot be so *in spite of* their spatio-temporal nature; on the contrary this must be related to their commensurability as the corporeality of a ruler is to its being extended--which is what enables it to measure. In this case, too, you cannot say: 'A ruler does measure in spite of its corporeality; of course a ruler which only has length would be the Ideal, you might say the *pure* ruler'. No, if a body has length, there can be no length without a body and although I realize that in a certain sense only the ruler's length measures, what I put in my pocket still remains the ruler, the body, and isn't the length.

Page 81

49 Perhaps this whole difficulty stems from taking the time concept from time in physics and applying it to the course of immediate experience. It's a confusion of the time of the film strip with the time of the picture it projects. For 'time' has one meaning when we regard memory as the source of time, and another when we regard it as a picture preserved from a past event.

Page 81

If we take memory as a picture, then it's a picture of a physical event. The picture fades, and I notice how it has faded when I compare it with other evidence of what happened. In this case, memory is not the source of time, but a more or less reliable custodian of what 'actually' happened; and this is something we can know about in other ways, a physical event.--It's quite different if we now take memory to be the source of time. Here it isn't a picture, and cannot fade either--not in the sense in which a picture fades, becoming an ever less faithful representation of its object. Both ways of talking are in order, and are equally legitimate, but cannot be mixed together. It's clear of course that

Page Break 82

speaking of memory as a picture is only a metaphor; just as the way of speaking of images as 'pictures of objects in our minds' (or some such phrase) is a metaphor. We know what a picture is, but images are surely no kind of picture at all. For, in the first case I can see the picture and the object of which it is a picture. But in the other, things are obviously quite different. We have just used a metaphor and now the metaphor tyrannizes us. While in the language

of the metaphor, I am unable to move outside of the metaphor. It must lead to nonsense if you try to use the language of this metaphor to talk about memory as the source of our knowledge, the verification of our propositions. We can speak of present, past and future events in the physical world, but not of present, past and future images, if what we are calling an image is not to be yet another kind of physical object (say, a physical picture which takes the place of the body), but precisely that which is present. Thus we cannot use the concept of time, i.e. the syntactical rules that hold for the names of physical objects, in the world of the image [†1], that is, not where we adopt a radically different way of speaking.

Page 82

50 If memory is *no* kind of seeing into the past, how do we know at all that it is to be taken as referring to the past? We could then remember some incident and be in doubt whether in our memory image we have a picture of the past or of the future.

Page 82

We can of course say: I do not see the past, only a *picture* of the past. But how do I know it's a picture of the *past* unless this belongs to the essence of a memory-image? Have we, say, learnt from experience to interpret these pictures as pictures of the past? But in this context what meaning would 'past' have at all?

Page 82

Yet it contradicts every concept of physical time that I should have perception into the past, and that again seems to mean nothing

Page Break 83

else than that the concept of time in the first system must be radically different from that in physics.

Page 83

Can I conceive the time in which the experiences of visual space occur without experiences of sound? It appears so. And yet how strange that something should be able to have a form, which would also be conceivable without *this* content. Or does a man who has been given hearing also learn a new time along with it?

Page 83

The traditional questions are not suited to a logical investigation of phenomena. These generate their own questions, or rather, give their own answers.

Page 83

51 If I compare the facts of immediate experience with the pictures on the screen and the facts of physics with pictures in the film strip, on the film strip there is a present picture and past and future pictures. But on the screen, there is only the present.

Page 83

What is characteristic about this image is that in using it I regard the future as preformed.

Page 83

There's a point in saying future events are pre-formed if it belongs to the *essence* of time that it does not break off. For then we can say: something will happen, it's only that I don't know what. And in the world of physics we can say that.

Page 83

52 It's strange that in ordinary life we are not troubled by the feeling that the phenomenon is slipping away from us, the constant flux of appearance, but only when we philosophize. This indicates that what is in question here is an idea suggested by a misapplication of our language.

Page 83

The feeling we have is that the present disappears into the past without our being able to prevent it. And here we are obviously using the picture of a film strip remorselessly moving past us, that we are unable to stop. But it is of course just as clear that the picture is misapplied: that we cannot say 'Time flows' if by time we mean the possibility of change. What we are looking at here is really the possibility of motion: and so the logical form of motion.

Page Break 84

Page 84

In this connection it appears to us as if memory were a somewhat secondary sort of experience, when compared with experience of the present. We say 'We can *only* remember that'. As though in a primary sense memory were a somewhat faint and uncertain picture of what we originally had before us in full clarity.

Page 84

In the language of physical objects, that's so: I say: 'I *only* have a *vague* memory of this house.'

53 And why not let matters rest there? For this way of talking surely says everything we want to say, and everything that can be said. But we wish to say that it can also be put *differently*; and that is important.

It is as if the emphasis is placed elsewhere in this other way of speaking: for the words 'seem', 'error', etc., have a certain emotional overtone which doesn't belong to the essence of the phenomena. In a way it's connected with the will and not merely with cognition.

We talk for instance of an optical illusion and associate this expression with the idea of a mistake, although of course it isn't essential that there should be any mistake; and if appearance were normally more important in our lives than the results of measurement, then language would also show a different attitude to this phenomenon.

There is not--as I used to believe--a primary language as opposed to our ordinary language, the 'secondary' one. But one could speak of a primary language as opposed to ours in so far as the former would not permit any way of expressing a preference for certain phenomena over others; it would have to be, so to speak, absolutely *impartial*.

54 What belongs to the essence of the world cannot be expressed by language.

For this reason, it cannot *say* that everything flows. Language can only say those things that we can also imagine otherwise.

That everything flows must be expressed in the application of language, and in fact not in one kind of application as opposed to another but in *the* application. In anything we would ever call the application of language.

By application I understand what makes the combination of sounds or marks into a language at all. In the sense that it is the application which makes the rod with marks on it into a *measuring rod* [†1]: *putting language up against* reality.

We are tempted to say: only the experience of the present moment has reality. And then the first reply must be: As opposed to what?

Does it imply I didn't get up this morning? (For if so, it would be dubious.) But that is not what we mean. Does it mean that an event that I'm not remembering at this instant didn't occur? Not that either.

The proposition that only the present experience has reality appears to contain the last consequence of solipsism. And in a sense that is so; only what it is able to say amounts to just as little as can be said by solipsism.--For what belongs to the essence of the world simply *cannot* be said. And philosophy, if it were to say anything, would have to describe the essence of the world.

But the essence of language is a picture of the essence of the world; and philosophy as custodian of grammar can in fact grasp the essence of the world, only not in the propositions of language, but in rules for this language which exclude nonsensical combinations of signs.

If someone says, only the *present experience* has reality, then the word 'present' must be redundant here, as the word 'I' is in other contexts. For it cannot mean *present* as opposed to past and future.--Something else must be meant by the word, something that isn't *in* a space, but is itself a space. That is to say, not something bordering on something else (from which it could therefore be limited off). And so, something language cannot legitimately set in relief.

The present we are talking about here is not the frame in the film reel that is in front of the projector's lens at precisely this moment, as opposed to the frames before and after it, which have already been there or are yet to

come; but the picture on the screen which would illegitimately be called present, since 'present' would not be used here to distinguish it from past and future. And so it is a meaningless epithet.

Page 86

55 There are, admittedly, very interesting, completely general propositions of great importance, therefore propositions describing an actual experience which might have been otherwise, but just *is as it is*. For instance, that I have only *one* body. That my sensations never reach out beyond this body (except in cases where someone has had a limb, e.g. an arm, amputated, and yet feels pain in his fingers). These are remarkable and interesting facts.

Page 86

But it does *not* belong in this category, if someone says I cannot remember the future. For that means nothing, and, like its opposite, is something inconceivable.

Page 86

That I always see with my *eyes* when I am awake is on the other hand a remarkable and interesting fact. Equally, it is important that my visual field is almost incessantly in a state of flux.

Page 86

'I' clearly refers to my body, for *I* am in this room; and 'I' is essentially something that is in a place, and in a place belonging to the same space as the one the other bodies are in too.

Page 86

From the very outset 'Realism', 'Idealism', etc., are names which belong to metaphysics. That is, they indicate that their adherents believe they can say something specific about the essence of the world.

Page 86

56 Anyone wishing to contest the proposition that only the present experience is real (which is just as wrong as to maintain it) will perhaps ask whether then a proposition like 'Julius Caesar crossed the Alps' merely describes my present mental state which is occupied with the matter. And of course the answer is: no, it

Page Break 87

describes an event which we believe happened ca. 2,000 years ago. That is, if the word 'describes' is construed in the same way as in the sentence 'The proposition "I am writing" *describes* what I am at present doing'. The name Julius Caesar designates a person. But what does all that amount to? I seem to be fighting shy of the genuinely philosophical answer! Propositions dealing with people, i.e. containing proper names, can be verified in very different ways.--We still might find Caesar's corpse: that this is thinkable is directly connected with the sense of the proposition about Caesar. But also that a manuscript might be found from which it emerged that such a man never lived and that the accounts of his existence were concocted for particular purposes. Propositions about Julius Caesar must, therefore, have a sense of a sort that covers this possibility. If I utter the proposition: I can see a red patch crossing a green one, the possibilities provided for in 'Julius Caesar crossed the Alps' are not present here, and to that extent I can say that the proposition about Caesar has its sense in a more indirect way than this one.

Page 87

Everything which, if it occurred, would legitimately confirm a belief, determines logically the nature of this belief. That is, it shows something about the logical nature of the belief.

Page 87

The proposition about Julius Caesar is simply a framework (like that about any other person) that admits of widely differing verifications, although not all those it would allow in speaking of other people--of living people, for instance.

Page 87

Isn't all that I mean: between the proposition and its verification there is no go-between negotiating this verification?

Page 87

Even our ordinary language has of course to provide for all cases of uncertainty, and if we have any philosophical objection to it, this can only be because in certain cases it gives rise to misinterpretations.

Page Break 88

VI

Page 88

57 One of the most misleading representational techniques in our language is the use of the word 'I', particularly when it is used in representing immediate experience, as in 'I can see a red patch'.

Page 88

It would be instructive to replace this way of speaking by another in which immediate experience would be represented without using the personal pronoun; for then we'd be able to see that the previous representation wasn't

essential to the facts. Not that the representation would be in any sense more correct than the old one, but it would serve to show clearly what was logically essential in the representation.

Page 88

The worst philosophical errors always arise when we try to apply our ordinary--physical--language in the area of the immediately given.

Page 88

If, for instance, you ask, 'Does the box still exist when I'm not looking at it?', the only right answer would be 'Of course, unless someone has taken it away or destroyed it'. Naturally, a philosopher would be dissatisfied with this answer, but it would quite rightly reduce his way of formulating the question *ad absurdum*.

Page 88

All our forms of speech are taken from ordinary, physical language and cannot be used in epistemology or phenomenology without casting a distorting light on their objects.

Page 88

The very expression 'I can perceive x ' is itself taken from the idioms of physics, and x ought to be a physical object--e.g. a body--here. Things have already gone wrong if this expression is used in phenomenology, where x must refer to a datum. For then 'I' and 'perceive' also cannot have their previous senses.

Page 88

58 We could adopt the following way of representing matters: if I, L. W., have toothache, then that is expressed by means of the proposition 'There is toothache'. But if that is so, what we now

Page Break 89

express by the proposition 'A has toothache', is put as follows: 'A is behaving as L. W. does when there is toothache'. Similarly we shall say 'It is thinking' [†1] and 'A is behaving as L. W. does when it is thinking'. (You could imagine a despotic oriental state where the language is formed with the despot as its centre and his name instead of L. W.) It's evident that this way of speaking is equivalent to ours when it comes to questions of intelligibility and freedom from ambiguity. But it's equally clear that this language could have anyone at all as its centre.

Page 89

Now, among all the languages with different people as their centres, each of which I can understand, the one with me as its centre has a privileged status. This language is particularly adequate. How am I to express that? That is, how can I rightly represent its special advantage in words? This can't be done. For, if I do it in the language with me as its centre, then the exceptional status of the description of this language in its own terms is nothing very remarkable, and in the terms of another language my language occupies no privileged status whatever.--The privileged status lies in the application, and if I describe this application, the privileged status again doesn't find expression, since the description depends on the language in which it's couched. And now, which description gives just that which I have in mind depends again on the application.

Page 89

Only their application really differentiates languages; but if we disregard this, all languages are equivalent. All these languages only describe one single, incomparable thing and *cannot* represent anything else. (Both these approaches must lead to the same result: first, that what is represented is not one thing among others, that it is not capable of being contrasted with anything; second, that I cannot express the advantage of *my* language.)

Page 89

59 It isn't possible to believe something for which you cannot imagine some kind of verification.

Page 89

If I say I believe that someone is sad, it's as though I am seeing his behaviour through the medium of sadness, from the viewpoint

Page Break 90

of sadness. But could you say: 'It looks to me as if I'm sad, my head is drooping so'?

Page 90

60 Not only does epistemology pay no attention to the truth or falsity of genuine propositions, it's even a philosophical method of focusing on precisely those propositions whose content seems to us as physically impossible as can be imagined (e.g. that someone has an ache in someone else's tooth). In this way, epistemology highlights the fact that its domain includes everything that can possibly be thought.

Page 90

Does it make *sense* to say that two people have the same body? That is an uncommonly important and

interesting question. If it makes no sense, then that means--I believe--that only our bodies are the principle of individuation. It is clearly imaginable that I should feel a pain in the hand of a different body from the one called my own. But suppose now that my old body were to become completely insensible and inert and from then on I only felt my pains in the other body?

Page 90

You could say: Philosophy is constantly gathering a store of propositions without worrying about their truth or falsity; only in the cases of logic and mathematics does it have to do exclusively with the 'true' propositions.

Page 90

61 In the sense of the phrase 'sense data' in which it is inconceivable that someone else should have them, it cannot, for this very reason, be said that someone else does not have them. And by the same token, it's senseless to say that *I*, as opposed to someone else, *have* them.

Page 90

We say, 'I *cannot* feel your toothache'; when we say this, do we only mean that so far we have never as a matter of fact felt someone else's toothache? Isn't it, rather, that it's logically impossible?

Page Break 91

Page 91

What distinguishes *his* toothache from *mine*? If the word 'toothache' means the same in 'I have toothache' and 'He has toothache', what does it then mean to say he can't have the same toothache as I do? How are toothaches to be distinguished from one another? By intensity and similar characteristics, and by location. But suppose these are the same in the two cases? But if it is objected that the distinction is simply that in the one case *I* have it, in the other *he*; then the owner is a defining mark of the toothache itself; but then what does the proposition 'I have toothache' (or someone else does) assert? Nothing at all.

Page 91

If the word 'toothache' has the same meaning in both cases, then we must be able to compare the toothaches of the two people; and if their intensities, etc. coincide, they're the same. Just as two suits have the *same* colour, if they match one another in brightness, saturation, etc.

Page 91

Equally, it's nonsense to say two people can't have the same sense datum, if by 'sense datum' what is *primary* is really intended.

Page 91

62 In explaining the proposition 'He has toothache', we even say something like: 'Quite simple, I know what it means for *me* to have toothache, and when I say he has toothache, I mean he now has what I once had.' But what does 'he' mean and what does '*have* toothache' mean? Is this a relation toothache once had to me and now has to him? So in that case I would also be conscious of toothache now and of his having it now, just as I can now see a wallet in his hand that I saw earlier in mine.

Page 91

Is there a sense in saying 'I have a pain, only I don't notice it'? For I could certainly substitute 'he has' for 'I have' in this proposition. And conversely, if the propositions 'He has a pain' and 'I have a pain' are logically on a par, I must be able to substitute 'I have' for 'he has' in the proposition 'He has a pain that I can't feel'.--I might also put it like this: only in so far as I can have a pain I don't

Page Break 92

feel can he have a pain I don't feel. Then it might still be the case that in fact I always feel the pain I have, but it must make sense to deny that I do.

Page 92

'I have no pain' means: if I compare the proposition 'I have a pain' with reality, it turns out false--so I must be in a position to compare the proposition with what is in fact the case. And the possibility of such a comparison--even though the result may be negative--is what we mean when we say: what is the case must happen in the same space as what is denied; only it must be *otherwise*.

Page 92

63 Admittedly the concept of toothache as a datum of feeling can be applied to someone else's tooth just as readily as it can to mine, but only in the sense that it might well be perfectly possible to feel pain in a tooth in someone else's mouth. According to our present way of speaking we wouldn't, however, express this fact in the words 'I feel his toothache' but by saying 'I've got a pain in his tooth'. Now we may say: Of course you haven't got his toothache, for it is now more than possible that he will say, 'I don't feel anything in this tooth'. And in such a situation, am I supposed to say 'You're lying, I can feel how your tooth is aching'?

When I feel sorry for someone with toothache, I put myself in his place. But I put *myself* in his place.

The question is, whether it makes sense to say: 'Only A can verify the proposition "A is in pain", I can't'. But what would it be like if this were false, and *I* could verify it: can that mean anything other than that I'd have to feel pain? But would that be a verification? Let's not forget: it's nonsense to say *I* must feel *my* or *his* pain.

We might also put the question like this: What in my experience justifies the 'my' in 'I feel *my* pain'? Where is the multiplicity in the feeling that justifies this word? And it can only be justified if we could also replace it by another word.

64 'I have a pain' is a sign of a completely different kind when I am using the proposition, from what it is to me on the lips of another; the reason being that it is senseless, as far as I'm concerned, on the lips of another until I know through which mouth it was expressed. The propositional sign in this case doesn't consist in the sound alone, but in the fact that the sound came out of this mouth. Whereas in the case in which I say or think it, the sign is the sound itself.

Suppose I had stabbing pains in my right knee and my right leg jerked with every pang. At the same time I see someone else whose leg is jerking like mine and he complains of stabbing pains; and while this is going on my left leg begins jerking like the right although I can't feel any pain in my left knee. Now I say: the other fellow obviously has the same pains in his knee as I've got in my right knee. But what about my left knee, isn't it precisely the same case here as that of the other's knee?

If I say 'A has toothache', I use the image of feeling pain in the same way as, say, the concept of flowing when I talk of an electric current flowing.

The two hypotheses that other people have toothache and that they behave just as I do but don't have toothache, possibly have identical senses. That is, if I had, for example, learnt the second form of expression, I would talk in a pitying tone of voice about people who don't have toothache, but are behaving as I do when I have.

Can I imagine pains in the tips of my nails, or in my hair? Isn't that just as possible or impossible as it is to imagine a pain in any part of the body whatever in which I have none at the moment, and cannot remember having had any?

65 The logic of our language is so difficult to grasp at this point: our language employs the phrases 'my pain' and 'his pain', and also the expressions 'I have (or feel) a pain' and 'He has (or feels) a pain'. An expression 'I feel my pain' or 'I feel his pain' is nonsense. And it seems to me that, at bottom, the entire controversy over behaviourism turns on this.

The experience of feeling pain is not that a person 'I' has something.

I distinguish an intensity, a location, etc. in the pain, but not an owner.

What sort of a thing would a pain be that no one *has*? Pain belonging to no one at all?

Pain is represented as something we can perceive in the sense in which we perceive a matchbox. What is unpleasant is then naturally not the pain, only perceiving it.

When I am sorry for someone else because he's in pain, I do of course imagine the pain, but I imagine that *I* have it.

Is it also to be possible for me to imagine the pain of a tooth lying on the table, or a teapot's pain? Are we perhaps to say: it merely isn't true that the teapot is in pain, but I can imagine it being so?!

The two hypotheses, that others have pain, and that they don't and merely behave as I do when I have, must have identical senses if every *possible* experience confirming the one confirms the other

as well. In other words, if a decision between them on the basis of experience is inconceivable.

To say that others have no pain, presupposes that it makes sense to say they do have pains.

I believe it's clear we say other people have pains in the same sense as we say a chair has none.

66 What would it be like if I had two bodies, i.e. my body were composed of two separate organisms?

Here again, I think, we see the way in which the self is not on a par with others, for if everyone else had two bodies, I wouldn't be able to tell that this was so.

Can I imagine experience with two bodies? Certainly not visual experience.

The phenomenon of feeling toothache I am familiar with is represented in the idioms of ordinary language by 'I have a pain in such-and-such a tooth'. Not by an expression of the kind 'In this place there is a feeling of pain'. The *whole* field of this experience is described in this language by expressions of the form 'I have...'. Propositions of the form 'N has toothache' are reserved for a totally different field. So we shouldn't be surprised when for propositions of the form 'N has toothache', there is nothing left that links with experience in the same way as in the first case.

Philosophers who believe you can, in a manner of speaking, extend experience by thinking, ought to remember that you can transmit speech over the telephone, but not measles.

Similarly I cannot at will experience time as bounded, or the visual field as homogeneous, etc.

Visual space and retina. It's as if you were to project a sphere orthogonally on to a plane, for instance in the way in which you represent the two hemispheres of the globe in an atlas, and now someone might believe that what's on the page surrounding the two projections of the sphere somehow still corresponds to a possible extension of what is to be found on the sphere. The point is that here a *complete space* is projected onto a *part* of another space; and it is like this with the limits of language in a dictionary.

If someone believes he can imagine four-dimensional space, then why not also four-dimensional colours--colours which in addition to the degree of saturation, hue and intensity of light, are susceptible of being determined in yet a fourth way.

VII

67 Suppose I had such a good memory that I could remember all my sense impressions. In that case, there would, *prima facie*, be nothing to prevent me from describing them. This would be a biography. And why shouldn't I be able to leave everything hypothetical out of this description?

I could, e.g., represent the visual images plastically, perhaps with plaster-cast figures on a reduced scale which I would only finish as far as I had actually seen them, designating the rest as inessential by shading or some other means.

So far everything would be fine. But what about the time I take to make this representation? I'm assuming I'd be able to keep pace with my memory in 'writing' this language--producing this representation. But if we suppose I then read the description through, isn't it now hypothetical after all?

Let's imagine a representation such as this: the bodies I seem to see are moved by a mechanism in such a

way that they would give the visual images to be represented to two eyes fixed at a particular place in the model. The visual image described is then determined from the position of the eyes in the model and from the position and motion of the bodies.

Page 97

We could imagine that the mechanism could be driven by turning a crank and in that way the description 'read off'.

Page 97

68 Isn't it clear that this would be the most immediate description we can possibly imagine? That is to say, that anything which tried to be more immediate still would inevitably cease to be a description.

Page 97

Instead of a description, what would then come out would be

Page Break 98

that inarticulate sound with which many writers would like to begin philosophy. ('I have, knowing of my knowledge, consciousness of something.')

Page 98

You simply can't begin before the beginning.

Page 98

Language itself belongs to the second system. If I describe a language, I am essentially describing something that belongs to physics. But how can a physical language describe the phenomenal?

Page 98

69 Isn't it like this: a phenomenon (specious present) contains time, but isn't in time?

Page 98

Its form is time, but it has no place in time.

Page 98

Whereas language unwinds in time.

Page 98

What we understand by the word 'language' unwinds in physical time. (As is made perfectly clear by the comparison with a mechanism.)

Page 98

Only what corresponds to this mechanism in the primary world could be the primary language.

Page 98

I mean: what I call a sign must be what is called a sign in grammar; something on the film, not on the screen.

Page 98

'I cannot tell whether...' only makes sense if I *can* know, not when it's inconceivable.

Page 98

70 With our language we find ourselves, so to speak, in the domain of the film, not of the projected picture. And if I want to make music to accompany what is happening on the screen, whatever produces the music must again happen in the sphere of the film.

Page 98

On the other hand, it's clear we need a way of speaking with which we can represent the phenomena of visual space, isolated as such.

Page 98

'I can see a lamp standing on the table', says, in the way in which it has to be understood in our ordinary language, more than a

Page Break 99

description of visual space. 'It seems to me as if I were seeing a lamp standing on a table' would certainly be a correct description: but this form of words is misleading since it makes it look as though nothing actual were being described, but only something whose nature was unclear.

Page 99

Whereas 'it seems' is only meant to say that something is being described as a special case of a general rule, and all that is uncertain is whether further events will be capable of being described as special cases of the same rule.

Page 99

It seems as if there is a sine curve on the film, of which we can see particular parts.

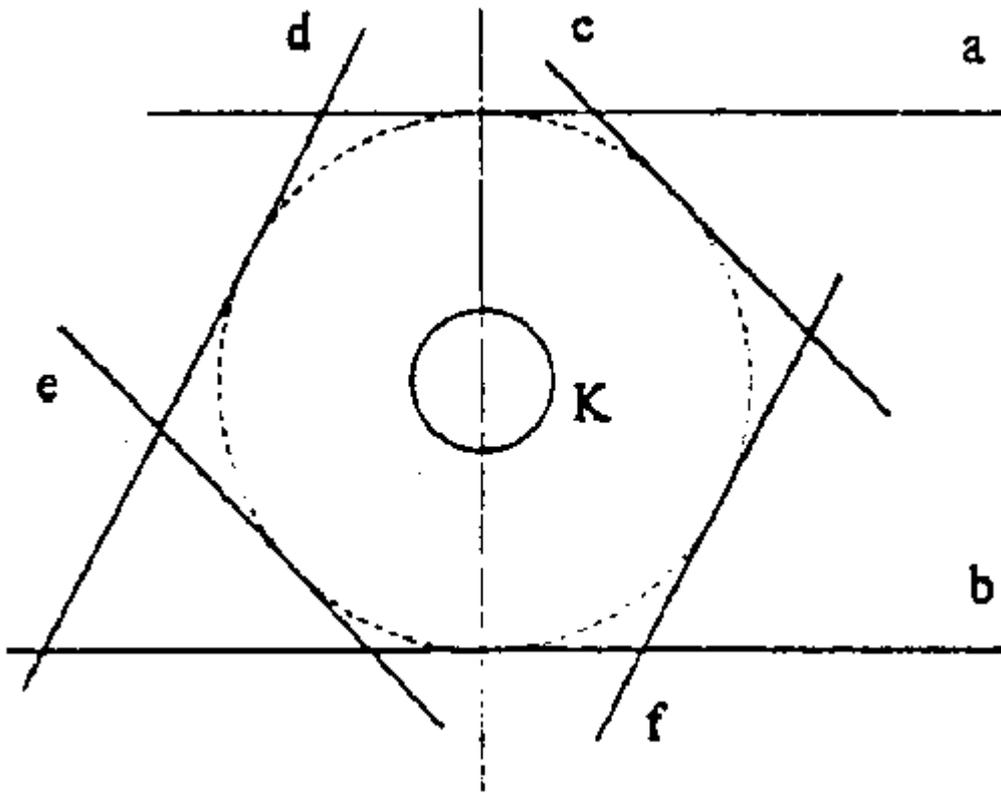

Page 99

That is to say, what we see can be described by means of a sine curve on the film, when the light projecting it

has been interrupted at particular points.

Page 99

A concentric circle seems to have been drawn round the circle K and a, b, c, d, e, f to have been drawn as tangents to it.

Page 99

71 It could, e.g., be practical under certain circumstances to give proper names to my hands and to those of other people, so that you

Page Break 100

wouldn't have to mention their relation to somebody when talking about them, since that relation isn't essential to the hands themselves; and the usual way of speaking could create the impression that its relation to its owner was something belonging to the essence of the hand itself.

Page 100

Visual space has essentially no owner.

Page 100

Let's assume that, with all the others, I can always see one particular object in visual space--viz my nose--. Someone else naturally doesn't see this object in the same way. Doesn't that mean, then, that the visual space I'm talking about *belongs to me*? And so is subjective? No. It has only been construed subjectively here, and an objective space opposed to it, which is, however, only a construction with visual space as its basis. In the--secondary--language of 'objective'--physical--space, visual space is called subjective, or rather, whatever in this language corresponds directly with visual space is called subjective. In the same way that one might say that in the language of real numbers whatever in their domain corresponds directly with the cardinal numbers is called the 'positive integers'.

Page 100

In the model described above neither the two eyes that see the objects, nor their position need be included. That's only *one* technique of representation. It does just as well if e.g. the part of the objects that is 'seen', is indicated by shading it in. Of course you can always work out the position of two eyes from the boundaries of this shaded area; but that only corresponds to translation from one way of speaking into another.

Page 100

The essential thing is that the representation of visual space is the representation of an object and contains no suggestion of a subject.

Page 100

72 Suppose all the parts of my body could be removed until only one eyeball was left; and this were to be firmly

fixed in a certain position, retaining its power of sight. How would the world appear to me? I wouldn't be able to perceive any part of myself,

Page Break 101

and supposing my eyeball to be transparent for me, I wouldn't be able to see myself in the mirror either. One question arising at this point is: would I be able to locate myself by means of my visual field? 'Locate myself', of course here only means to establish a particular structure for the visual space.

Page 101

Does anything now force me into interpreting the tree I see through my window as larger than the window? If I have a sense for the distance of objects from my eye, this is a justified interpretation. But even then it's a representation in a different space from visual space, for what corresponds to the tree in visual space is, surely, obviously smaller than what corresponds to the window.

Page 101

Or ought I to say: Well, that all depends on how you're using the words 'larger' and 'smaller'?

Page 101

And that's right: in visual space I can use the words 'larger' and 'smaller' both ways. And in one sense the visual mountain is smaller, and in the other larger, than the visual window.

Page 101

Suppose my eyeball were fixed behind the window, so that I would see most things through it. In that case this window could assume the role of a part of my body. What's near the window is near me. (I'm assuming I can see three-dimensionally with one eye.) In addition, I assume that I'm in a position to see my eyeball in the mirror, and perceive similar eyeballs on the trees outside, say.

Page 101

How can I in this case tell, or arrive at the assumption, that I see the world through the pupil of my eyeball? Surely not in an essentially different way from that of my seeing it through the window, or, say, through a hole in a board that my eye is directly behind.

Page 101

In fact, if my eye were in the open stuck on the end of a branch, my position could be made perfectly clear to me by someone bringing a ring closer and closer until in the end I could see

Page Break 102

everything through it. They could even bring up the old surroundings of my eye: cheek bones, nose, etc., and I would know where it all fits in.

Page 102

73 Does all this mean then that a visual image does essentially contain or presuppose a subject after all?

Page 102

Or isn't it rather that these experiments give me nothing but purely geometrical information?

Page 102

That is to say information that constantly only concerns the object.

Page 102

Objective information about reality.

Page 102

There isn't an eye belonging to me and eyes belonging to others in visual space. Only the space itself is asymmetrical, the objects in it are on a par. In the space of physics however this presents itself in such a way that one of the eyes which are on a par is singled out and called *my* eye.

Page 102

I want to know what's going on behind me and turn round. If I were prevented from doing this, wouldn't the idea that space stretches out around me remain? And that I could manage to see the objects now behind me by turning around. *Therefore* it's the possibility of turning around that leads me to this idea of space. The resulting space around me is thus a mixture of visual space and *the space of muscular sensation*.

Page 102

Without the feeling of the ability 'to turn around', my idea of space would be *essentially* different.

Page 102

Thus the detached, immovable eye wouldn't have the idea of a space all around it.

Page 102

74 Immediate experience cannot contain any contradiction. If it is beyond all speaking and contradicting, then the demand for an explanation cannot arise either: the feeling that there must be an explanation of what is happening,

since otherwise something would be amiss.

Page Break 103

Page 103

What about when we close our eyes: we don't stop seeing. But what we see in this case surely can't have any relation to an eye. And it's the same with a dream image. But even in the case of normal seeing, it's clear that the exceptional position of my body in visual space only derives from other feelings that are located in my body, and not from something purely visual.

Page 103

Even the word 'visual space' is unsuitable for our purpose, since it contains an allusion to a sense organ which is as inessential to the space as it is to a book that it belongs to a particular person; and it could be very misleading if our language were constructed in such a way that we couldn't use it to designate a book without relating it to an owner. It might lead to the idea that a book can only exist in relation to a person.

Page 103

75 If, now, phenomenological language isolates visual space and what goes on in it from everything else, how does it treat time? Is the time of 'visual' phenomena the time of our ordinary idioms of physics?

Page 103

It's clear we're able to recognize that two time intervals are equal. I could, e.g., imagine what happens in visual space being accompanied by the ticking of a metronome or a light flashing at regular intervals.

Page 103

To simplify matters, I'm imagining the changes in my visual space to be discontinuous, and, say, in time with the beats of the metronome. Then I can give a description of these changes (in which I use numbers to designate the beats).

Page 103

Suppose this description to be a prediction, which is now to be verified. Perhaps I know it by heart and now compare it with what actually happens. Everything hypothetical is avoided here, apart from what is contained in the presupposition that the description is given to me independently of the question of which elements in it are before me at precisely this moment.

Page Break 104

Page 104

The whole is a talking film, and the spoken word that goes with the events on the screen is just as fleeting as those events and not the same as the sound track. The sound track doesn't accompany the scenes on the screen.

Page 104

Does it now make any sense to say I could have been deceived by a demon and what I took for a description wasn't one at all, but a memory delusion? No, that can have no sense. A delusion that, *ex hypothesi*, cannot be unmasked isn't a delusion.

Page 104

And this means no more and no less than that the time of my memory is, in this instance, precisely the time which I'm describing.

Page 104

This isn't the same as time as it's usually understood: for that, there are any number of possible sources, such as the accounts other people give, etc. But here it is once again a matter of isolating the one time.

Page 104

If there are three pipes in which a black liquid, a yellow liquid and a red liquid are flowing respectively, and these combine at some point to make a brown, then the resulting liquid has its own way of flowing too; but all I want to say is that each of the liquids with a simple colour also has a way of flowing, and I wish to examine this at a point before the three have run into one another.

Page 104

Of course the word 'present' is also out of place here. For to what extent can we say of reality that it is present? Surely only if we embed it once more in a time that is foreign to it. In itself it isn't present. Rather, on the contrary, it contains a time.

Page Break 105

Page 105

76 One's first thought is that it's incompatible for two colours to be in *one* place at the same time. The next is that

VIII

two colours in one place simply combine to make another. But third comes the objection: how about the complementary colours? What do red and green make? Black perhaps? But do I then see green in the black colour?--But even apart from that: how about the mixed colours, e.g. mixtures of red and blue? These contain a greater or lesser element of red: what does that mean? It's clear what it means to say that something *is red*: but that it *contains* more or less red?--And different degrees of red are incompatible with one another. Someone might perhaps imagine this being explained by supposing that certain small quantities of red added together would yield a specified degree of red. But in that case what does it mean if we say, for example, that five of these quantities of red are present? It cannot, of course, be a logical product of quantity no. 1 being present, and quantity no. 2 etc., up to 5; for how would these be distinguished from one another? Thus the proposition that 5 degrees of red are present can't be analysed like this. Neither can I have a concluding proposition that this is all the red that is present in this colour: for there is no sense in saying that no more red is needed, since I can't add quantities of red with the 'and' of logic.

Page 105

Neither does it mean anything to say that a rod which is 3 yards long is 2 yards long, because it is $2 + 1$ yards long, since we can't say it is 2 yards long and that it is 1 yard long. The length of 3 yards is something new.

Page 105

And yet I can say, when I see two different red-blues: there's an even redder blue than the redder of these two. That is to say, from the given I can construct what is not given.

Page 105

You could say that the colours have an elementary affinity with one another.

Page Break 106

Page 106

That makes it look as if a construction might be possible within the elementary proposition. That is to say, as if there were a construction in logic which didn't work by means of truth functions.

Page 106

What's more, it also seems that these constructions have an effect on one proposition's following logically from another.

Page 106

For, if different degrees exclude one another it follows from the presence of one that the other is not present. In that case, two elementary propositions can contradict one another.

Page 106

77 How is it possible for $f(a)$ and $f(b)$ to contradict one another, as certainly seems to be the case? For instance, if I say 'There is red here now' and 'There is green here now'?

Page 106

This is connected with the idea of a *complete description*: 'The patch is green' describes the patch completely, and there's no room left for another colour.

Page 106

It's no help either that red and green can, in a manner of speaking, pass one another by in the dimension of time: for, suppose I say that throughout a certain period of time a patch was red and that it was green?

Page 106

If I say for example that a patch is simultaneously light red and dark red, I imagine as I say it that the one shade covers the other. But then is there still a sense in saying the patch has the shade that is invisible and covered over?

Page 106

Does it make any sense at all to say that a perfectly black surface is white, only we don't see the white because it is covered by the black? And why does the black cover the white and not vice versa?

Page 106

If a patch has a visible and an invisible colour, then at any rate it has these colours in quite different senses.

Page 106

78 If $f(r)$ and $f(g)$ contradict one another, it is because r and g completely occupy the f and cannot both be in it. But that doesn't show itself in our signs. But it must show itself if we look, not at

Page Break 107

the sign, but at the symbol. For since this includes the form of the objects, then the impossibility of ' $f(r)$ &unk; $f(g)$ ' must show itself there, in this form.

Page 107

It must be possible for the contradiction to show itself entirely in the symbolism, for if I say of a patch that it

is red and green, it is certainly at most only one of these two, and the contradiction must be contained in the *sense* of the two propositions.

Page 107

That two colours won't fit at the same time in the same place must be contained in their form and the form of space.

Page 107

But the symbols do contain the form of colour and of space, and if, say, a letter designates now a colour, now a sound, it's a *different* symbol on the two occasions; and this shows in the fact that different syntactical rules hold for it.

Page 107

Of course, this doesn't mean that inference could now be not only formal, but also material.--Sense follows from sense and so form from form.

Page 107

'Red and green won't both fit into the same place' doesn't mean that they are as a matter of fact never together, but that you can't even say they are together, or, consequently, that they are never together.

Page 107

79 But that would imply that I can write down two particular propositions, but not their logical product.

Page 107

The two propositions collide in the object.

Page 107

The proposition $f(g) \& \text{unk}; f(r)$ isn't nonsense, since not *all* truth possibilities disappear, even if they are all rejected. We can, however, say that the ' \bullet ' has a different meaning here, since ' $x \bullet y$ ' usually means ($TFFF$); here, on the other hand, it means (FFF). And something analogous holds for ' $x \vee y$ ', etc.

Page 107

80 A yellow tinge is not the colour yellow.

Page Break 108

Page 108

Strictly, I cannot *mix* yellow and red, i.e. not strictly see them at the same time, since if I want to see yellow in this place, the red must leave it and vice versa.

Page 108

It's clear, as I've said, that the proposition that a colour contains five tints of yellow cannot say it contains tint no. 1 and it contains tint no. 2 etc. On the contrary the addition of the tints must occur within the elementary proposition. But what if these tints are objects lined up like links in a chain in a certain way; and now in one proposition we are speaking of five such links, and in another proposition of three. All right, but these propositions must exclude one another, while yet not being analysable.--But then do F_5 and F_6 have to exclude each other? Can't I say, F_n doesn't mean that the colour contains *only* n tints, but that it contains *at least* n tints? It contains *only* n tints would be expressed by the proposition $F(n) \bullet \sim F(n + 1)$. But even then the elementary propositions aren't independent of one another, since $F(n - 1)$ at any rate still follows from $F(n)$, and $F(5)$ contradicts $\sim F(4)$.

Page 108

The proposition asserting a certain degree of a property contradicts on the one interpretation the specification of any other degree and on the other interpretation it follows from the specification of any higher degree.

Page 108

A conception which makes use of a product $aR_x \& \text{unk}; xR_y \bullet yR_b$ is inadequate too, since I must be able to distinguish the things x, y , etc., if they are to yield a distance.

Page 108

A mixed colour, or better, a colour intermediate between blue and red is such in virtue of an internal relation to the structures of blue and red. But this internal relation is *elementary*. That is, it doesn't consist in the proposition ' a is blue-red' representing a logical product of ' a is blue' and ' a is red'.

Page 108

To say that a particular colour is now in a place is to describe that place *completely*.

Page 108

81 Besides, the position is no different for colours than for sounds or electrical charges.

Page Break 109

Page 109

In every case it's a question of the complete description of a certain state at *one* point or at the same time.

Wouldn't the following schema be possible: the colour at a point isn't described by allocating *one* number to a point, but by allocating *several* numbers. Only a mixture of such numbers makes the colour; and to describe the colour in full I need the proposition that *this* mixture is the complete mixture, i.e. that nothing more can be added. That would be like describing the taste of a dish by listing its ingredients; then I must add at the end that these are *all* the ingredients.

In this way we could say the colour too is definitely described when all its ingredients have been specified, of course with the addition that these are all there are.

But how is such an addition to be made? If in the form of a *proposition*, then the incomplete description would already have to be one as well. And if not in the form of a proposition, but by some sort of indication in the first proposition, how can I then bring it about that a second proposition of the same form contradicts the first?

Two elementary propositions can't contradict one another.

What about all assertions which appear to be similar, such as: a point mass can only have *one* velocity at a time, there can only be *one* charge at a point of an electrical field, at one point of a warm surface only *one* temperature at one time, at one point in a boiler only *one* pressure etc.? No one can doubt that these are all self-evident and that their denials are contradictions.

82 This is how it is, what I said in the *Tractatus* doesn't exhaust the grammatical rules for 'and', 'not', 'or' etc.; there are rules for the truth functions which also deal with the elementary part of the proposition.

In which case, propositions turn out to be even more like yardsticks than I previously believed.--The fact that *one* measurement is right automatically excludes all others. I say automatically: just as all the graduation marks are on *one* rod, the propositions corresponding to the graduation marks similarly belong together, and we can't measure with one of them without simultaneously measuring with all the others.--It isn't a proposition which I put against reality as a yardstick, it's a *system* of propositions [†1].

We could now lay down the rule that the same yardstick may only be applied once in one proposition. Or that the parts corresponding to different applications of one yardstick should be collated.

'I haven't got stomach-ache' may be compared to the proposition 'These apples cost nothing'. The point is that they don't cost any money, not that they don't cost any snow or any trouble. The zero is the zero point of *one* scale. And since I can't be given any point on the yardstick without being given the yardstick, I can't be given its zero point either. 'I haven't got a pain' doesn't refer to a condition in which there can be no talk of pain, on the contrary we're talking about pain. The proposition presupposes the capacity for feeling pain, and this can't be a 'physiological capacity'--for otherwise how would we know what it was a capacity for--it's a logical possibility.--I describe my present state by alluding to something that isn't the case. If this allusion is needed for the description (and isn't merely an ornament), there must be something in my present state making it necessary to mention (allude to) this. I compare this state with another, it must therefore be comparable with it. It too must be located in pain-space, even if at a different point.--Otherwise my proposition would mean something like: my present state has *nothing to do* with a painful one; rather in the way I might say the colour of this rose has nothing to do with Caesar's conquest

of Gaul. That is, there's no connection between them. But I mean precisely that there is a connection between my present state and a painful one.

I don't describe a state of affairs by mentioning something that has nothing to do with it and stating it has nothing to do with it. That wouldn't be a negative description.

'The sense consists in the possibility of recognition', but this is a logical possibility. I must be in the space in which what is to be expected is located.

83 The concept of an 'elementary proposition' now loses all of its earlier significance.

The rules for 'and', 'or', 'not' etc., which I represented by means of the T-F notation, are *a part* of the grammar of these words, but not *the whole*.

The concept of independent co-ordinates of description: the propositions joined, e.g., by 'and' are not independent of one another, they form *one* picture and can be tested for their compatibility or incompatibility.

In my old conception of an elementary proposition there was no determination of the value of a co-ordinate; although my remark that a coloured body is in a colour-space, etc., should have put me straight on to this.

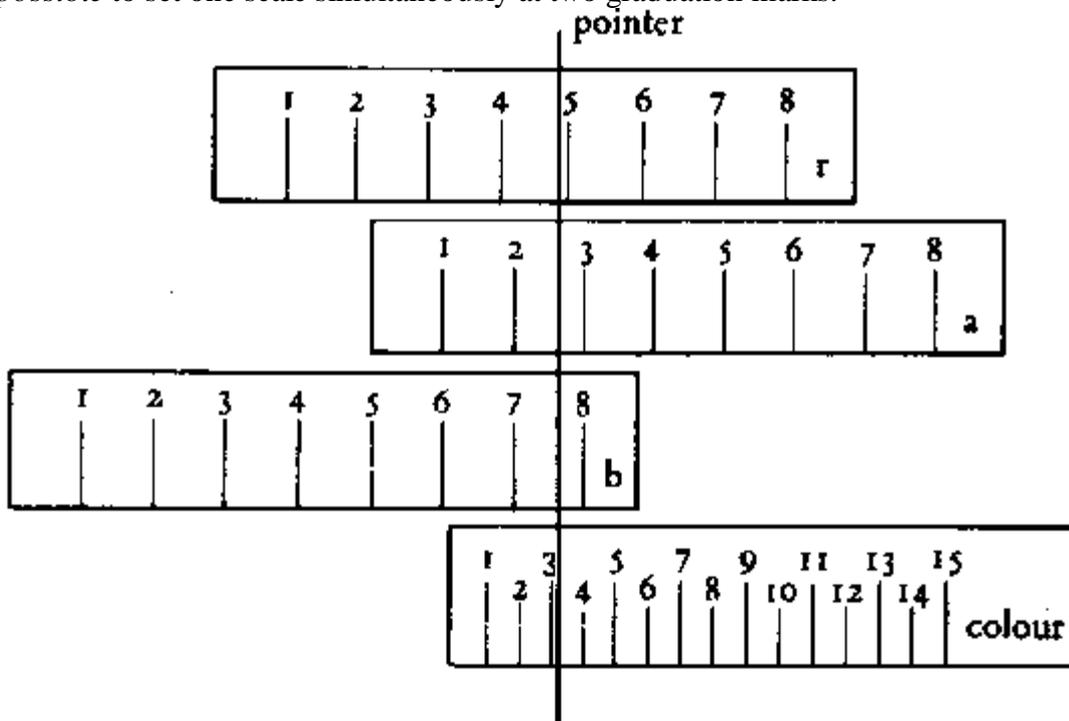

A co-ordinate of reality may only be determined *once*.

If I wanted to represent the general standpoint I would say: 'You should not say now one thing and now another about the same matter.' Where the matter in question would be the coordinate to which I can give *one* value and no more.

84 The situation is misrepresented if we say we may not ascribe to an object two incompatible attributes. For seen like that, it looks as if in every case we must first investigate whether two determinations are incompatible or not. The truth is, *two* determinations of the same kind (co-ordinate) are impossible.

What we have recognized is simply that we are dealing with yardsticks, and not in some fashion with isolated graduation marks.

In that case every assertion would consist, as it were, in setting a number of scales (yardsticks) and it's *impossible* to set one scale simultaneously at two graduation marks.

For instance, that would be the claim that a coloured circle, of colour... and radius... was located at.... We might think of signals on a ship: 'Stop', 'Full Speed Ahead', etc.

Incidentally, they don't have to be yardsticks. For you can't call a dial with two signals a yardstick.

85 That every proposition contains time in some way or other appears to us to be accidental, when compared with the fact that the truth-functions can be applied to any proposition.

The latter seems to be connected with their nature as propositions, the former with the nature of the reality we encounter.

True-false, and the truth functions, go with the representation of reality by propositions. If someone said: Very well, how do you know that the whole of reality can be represented by propositions?, the reply is: I only know that it can be represented by propositions in so far as it can be represented by propositions, and to draw a line between a part which can and a part which can't be so represented is something I can't do in language. Language *means* the totality of propositions.

We could say: a proposition is that to which the truth functions may be applied.--The truth functions are essential to *language*.

86 Syntax prohibits a construction such as 'A is green and A is red' (one's first feeling is that it's almost as if this proposition had been done an injustice; as though it had been cheated of its rights as a proposition), but for 'A is green', the proposition 'A is red' is not, so to speak, *another* proposition--and that strictly is what the syntax fixes--but another form of the same proposition.

In this way syntax draws together the propositions that make *one* determination.

If I say I did *not* dream last night, I must still know where I would have to look for a dream (i.e. the proposition 'I dreamt', applied to this situation can at most be false, it cannot be nonsense).

I express the present situation by a setting--the negative one of the signal dial 'dreams--no dreams'. But in spite of its negative setting I must be able to distinguish it from other signal dials. I must know that *this* is the signal dial I have in my hand.

Someone might now ask: Does that imply you have, after all, felt something, so to speak, the hint of a dream, which makes you conscious of the place where a dream would have been? Or if I say 'I haven't got a pain in my arm', does that mean I have a sort of shadowy feeling, indicating the place where the pain would be? No, obviously not.

In what sense does the present, painless, state contain the possibility of pain?

If someone says 'For the word pain to have a meaning, it's necessary that pain should be recognized as such when it occurs', we may reply 'It's no more necessary than that the absence of pain should be recognized as such'.

'Pain' means, so to speak, the whole yardstick and not one of its graduation marks. That it is set at one particular graduation mark can only be expressed by means of a *proposition*.

IX

87 The general proposition 'I see a circle on a red background' appears simply to be a proposition which leaves possibilities open.

A sort of incomplete picture. A portrait in which, e.g. the eyes have not been painted in.

But what would this generality have to do with a totality of objects?

There must be incomplete elementary propositions from whose application the concept of generality derives.

This incomplete picture is, if we compare it with reality, right or wrong: depending on whether or not reality agrees with what can be read off from the picture.

(The theory of probability is connected with the fact that the more general, i.e. the more incomplete, description is more likely to fit the facts than the more complete one.)

Generality in this sense, therefore, enters into the theory of elementary propositions, and not into the theory of truth functions.

88 If I do not completely describe my visual field, but only a part of it, it is obvious that there is, as it were, a gap in the fact. There is obviously something left out.

If I were to paint a picture of this visual image, I would let the canvas show through at certain places. But of course the canvas also has a colour and occupies space. I could not leave *nothing* in the place where something was missing.

My description must therefore necessarily include the whole visual space--and its being coloured, even if it does not specify what the colour is at every place.

That is, it must still say that there is a colour at every place.

Does that mean that the description, in so far as it does not exhaust the space with constants, must exhaust it with variables?

To this one might object that you cannot describe a part of the visual field separated from the whole at all, since it is not even conceivable *on its own*.

But the form (the logical form) of the patch in fact presupposes the whole space. And if you can only describe the whole visual field, then why not only the whole flux of visual experience; for a visual image *can only* exist in time.

89 The question is this: can I leave some determination in a proposition open, *without* at the same time specifying precisely what the possibilities left open are?

Is the case of the general proposition 'A red circle is situated in the square' essentially different from a general assertion of numerical equality, such as 'I have as many jackets as trousers'? and is not this proposition for its part completely on all fours with 'There is *a* number of chairs in this room'? Of course, in everyday life you would not need to develop the disjunction of numbers very far. But however far you go, you must stop somewhere. The question here is always: How do I know such a proposition? Can I ever know it as an endless disjunction?

Even if the first case is construed in such a way that we can establish the position and size of the circle by taking measurements, even then the general proposition cannot be construed as a disjunction (or if so, then just as a finite one). For what then is the criterion for the general proposition, for the circle's being in the square? Either, nothing that has anything to do with a set of positions (or sizes), or else something that deals with a finite number of such positions.

90 Suppose this is my incomplete picture: a red circle stands on a differently coloured background with colour *x*. It is clear that this picture can be used as a proposition in a positive sense, but also in a negative one. In the negative sense it says what Russell expresses as $\sim(\exists x) \phi x$.

Now is there also in my account an analogue to Russell's

$(\exists x) \sim\phi x$? That would mean: there is an *x* of which it is not true that a red circle stands on a background with this colour. Or in other words: there is a colour of the background on which there does not stand a red circle. And in this context that is nonsense!

But how about the proposition 'There is a red ball which is not in the box'? Or 'There is a red circle not in the square'? That is once more a general description of a visual image. Here negation seems to be used in a different way. For it certainly seems as if I could express the proposition 'This circle is not in the square' so that the 'not' is placed *at the front of* the proposition.--But that seems to be an illusion. If you mean by the words 'this circle', 'the circle that I am pointing at', then this case of course falls into line, for then it says 'It is not the case that I am pointing at a circle in the square', but it does not say that I am pointing at a circle outside the square.

Page 117

This is connected with the fact that it's nonsense to give a circle a name. That is to say, I cannot say 'The circle *A* is not in the square'. For that would only make sense if it made sense to say 'The circle *A* is in the square' even when it wasn't.

Page 117

91 If generality no longer combines with truth functions into a homogeneous whole, then a negation cannot occur *within* the scope of a quantifier.

Page 117

Of course I could say: 'There is a red circle outside the square' means 'It is not the case that all red circles are in the square'. But what does 'all' refer to here?

Page 117

'All circles are in the square' can only mean, either 'A certain number of circles are in the square', or 'There is no circle outside'. But the proposition 'There is no circle outside' is once again the negation of a generalization and not the generalization of a negation.

Page Break 118

Page 118

92 If someone confronts us with the fact that language can express everything by means of nouns, adjectives and verbs, we can only say that then it is at any rate necessary to distinguish between entirely different kinds of nouns etc., since different grammatical rules hold for them. This is shown by the fact that it is not permissible to substitute them for one another. This shows that their being nouns is only an external characteristic and that we are in fact dealing with quite different parts of speech. The part of speech is only determined by *all* the grammatical rules which hold for a word, and seen from this point of view our language contains countless different parts of speech.

Page 118

If you give a body a name then you cannot in the same sense give names to its colour, its shape, its position, its surface. And vice versa.

Page 118

'*A*' is the name of a shape, not of a cluster of graphite particles.

Page 118

The different ways names are used correspond exactly to the different uses of the demonstrative pronoun. If I say: 'That is a chair', 'That is the place where it stood', 'That is the colour it had', the word '*that*' is used in that many different ways. (I cannot in the same sense point at a place, a colour, etc.)

Page 118

93 Imagine two planes, with figures on plane *I* that we wish to map on to plane *II* by some method of projection. It is then open to us to fix on a method of projection (such as orthogonal projection) and then to interpret the images on plane *II* according to this method of mapping. But we could also adopt a quite different procedure: we might for some reason lay down that the images on plane *II* should all be circles no matter what the figures on plane *I* may be. That is, different figures on *I* are mapped on to *II* by different methods of projection. In order in this case to construe the circles in *II* as images, I shall have to say for each circle what

Page Break 119

method of projection belongs to it. But the mere fact that a figure is represented on *II* as a circle will say nothing.--It is like this with reality if we map it onto subject-predicate propositions. The fact that we use subject-predicate propositions is only a matter of our notation. The subject-predicate form does not in itself amount to a logical form and is the way of expressing countless fundamentally different logical forms, like the circles on the second plane. The forms of the propositions: 'The plate is round', 'The man is tall', 'The patch is red', have nothing in common.

Page 119

One difficulty in the Fregean theory is the generality of the words 'concept' and 'object'. For even if you can count tables and tones and vibrations and thoughts, it is difficult to bracket them all together.

Page 119

Concept and object: but that is subject and predicate. And we have just said that there is not just one logical

form which is *the* subject-predicate form.

Page 119

94 That is to say, it is clear that once you have started doing arithmetic, you don't bother about functions and objects. Indeed, even if you decide only to deal with extensions, strangely enough you still ignore the form of the objects completely.

Page 119

There is a sense in which an object may not be described.

Page 119

That is, the description may ascribe to it no property whose absence would reduce the existence of the object itself to nothing, i.e. the description may not express what would be essential for the existence of the object.

Page 119

95 I see three circles in certain positions; I close my eyes, open them again and see three circles of the same size in different positions. Does it make sense to ask whether these are the same circles and which is which? Surely not. However, *while* I can see

Page Break 120

them, I can identify them (even if they move before my eyes, I can identify the circles in the new places with those that were in the earlier ones). If I give them names, close my eyes, open them again and see that the circles are in the same places, I can give to each its name once more. (I could still do this even if they had moved so as to exchange places.) In any case, I always name (directly or indirectly) a *location*.

Page 120

Would it be possible to discover a *new* colour? (For the man who is colour-blind is of course in the same position as ourselves, his colours form just as complete a system as ours; he does not see gaps where the remaining colours fit in.) (Comparison with mathematics.)

Page 120

If someone says that substance is indestructible, then what he is really after is that it is senseless in any context to speak of 'the destruction of a substance'--either to affirm or deny it.

Page 120

What characterizes propositions of the form 'This is...' is only the fact that the reality outside the so-called system of signs somehow enters into the symbol.

Page 120

96 Russell and Frege construe a concept as a sort of property of a thing. But it is very unnatural to construe the words 'man', 'tree', 'treatise', 'circle' as properties of a substratum.

Page 120

If a table is painted brown then it's easy to think of the wood as bearer of the property brown, and you can imagine what remains when the colour changes. Even in the case of *one* particular circle which appears now red, now blue. It is thus easy to imagine *what* is red, but difficult to imagine what is circular. What *remains* in this case, if form and colour alter? For position is part of the form, and it is arbitrary for me to lay down that the centre should stay fixed and the only changes in form be changes in the radius.

Page Break 121

Page 121

We must once more adhere to ordinary language and say that a *patch* is circular.

Page 121

It is clear that the phrase 'bearer of a property' in this context conveys a completely wrong--an impossible--picture. If I have a lump of clay, I can consider it as the bearer of a form, and that, roughly, is where this picture comes from.

Page 121

'The patch changes its form' and 'The lump of clay changes its form' are fundamentally different forms of proposition.

Page 121

You can say 'Measure whether *that* is a circle' or 'See whether *that* over there is a hat'. You can also say 'Measure whether *that* is a circle or an ellipse', but not '... whether that is a circle or a hat'; not 'See whether that is a hat or red'.

Page 121

If I point to a curve and say 'That is a circle', then someone can object that if it were not a circle, it would no longer be *that*. That is to say, what I mean by the word 'that' must be independent of what I assert about it.

Page 121

('Was *that* thunder or gunfire?' Here you could not ask 'Was that a noise?')

Page 121

97 Roughly speaking, the equation of a circle is the sign for the concept 'circle', if it does not have definite values substituted for the co-ordinates of its centre and for the radius, or even, if these are only given as lying within a certain range. The object falling under the concept is then a circle whose position and size have been fixed.

Page 121

How are two red circles of the same size distinguished? This question makes it sound as if they were pretty nearly one circle, and only distinguished by a nicety.

Page 121

In the technique of representation by equations, what is common is expressed by the form of the equation and the difference by the difference in the co-ordinates of the centres.

Page 121

So it is as if what corresponds with the objects falling under the concept were here the co-ordinates of the centres.

Page 121

Couldn't you then say, instead of 'This is a circle', 'This point

Page Break 122

is the centre of a circle'? For, to be the centre of a circle is an external property of the point.

Page 122

For the number pair that gives the co-ordinates of the centre is in fact not just anything, any more than the centre is: the number pair characterizes just what in the symbol constitutes the 'difference' of the circles.

Page 122

98 What is necessary to a description that--say--a book is in a certain position? The internal description of the book, i.e. of the concept, and a description of its place which it would be possible to give by giving the co-ordinates of three points. The proposition, 'Such a book is *here*', would then mean that it had *these* three triples of co-ordinates. For the specification of the 'here' must not pre-judge *what* is here.

Page 122

But doesn't it come to the same thing whether I say '*This* is a book' or 'Here is a book'? The proposition would then amount to saying 'Those are three particular corners of such a book'.

Page 122

Similarly you can also say 'This circle is the projection of a sphere' or 'This is a man's appearance'.

Page 122

All that I am saying comes back to this: $F(x)$ must be an *external* description of x .

Page 122

If in this sense I now say in three-dimensional space 'Here is a circle' and on another occasion 'Here is a sphere', are the two 'here's of the same type? Couldn't both refer to the three co-ordinates of the relevant centre-point? But, the position of the circle in three-dimensional space is not fixed by the coordinates of its centre.

Page 122

Suppose my visual field consisted of two red circles of the same size on a blue background: what occurs twice here and what once? And what does this question mean in any case?

Page 122

Here we have *one* colour, but *two* positions.

Page Break 123

X

Page 123

99 We can ask whether numbers are essentially concerned with concepts. I believe this amounts to asking whether it makes sense to ascribe a number to objects that haven't been brought under a concept. For instance, does it mean anything to say '*a* and *b* and *c* are three objects'? I think obviously not. Admittedly we have a feeling: Why talk about concepts; the number, of course, depends only on the *extension* of the concept, and once that has been determined, the concept may drop out of the picture. The concept is only a method for determining an extension, but the extension is autonomous and, in its essence, independent of the concept; for it's quite immaterial which concept we have used to determine the extension. That is the argument for the extensional viewpoint. The immediate objection to it is: if a concept is really only an expedient for arriving at an extension, then there is no place for concepts in arithmetic; in that case we must simply divorce a class completely from the concept which happens

to be associated with it; but if it isn't like that, then an extension independent of a concept is just a chimera, and in that case it's better not to speak of it at all, but only of the concept.

Page 123

How about the proposition ' $(\exists x, y, z) \bullet aRx \bullet xRy \bullet yRz \bullet zRb \vee aRy \bullet yRx \bullet xRz \bullet zRb \vee \text{etc.}$ ' (all combinations)? Can't I write this in the perfectly intelligible form: ' $(\exists 3)_x \bullet aRxRb$ '--say 'Three links are inserted between a and b '? Here we've formed the concept 'link between a and b '.

Page 123

(Things between these walls.)

Page 123

If I have two objects, then I can of course, at least hypothetically, bring them under one umbrella, but what characterizes the extension is still the class, and the concept encompassing it still only a makeshift, a pretext.

Page Break 124

Page 124

100 Numbers are pictures of the extensions of concepts.

Page 124

Now we could regard the extension of a concept as an object, whose name, like any other, has sense only in the context of a proposition. Admittedly, ' a and b and c ' has no sense, it isn't a proposition. But then neither is ' a ' a proposition.

$$(E1)_x \phi x \bullet (E1)_x \psi x \bullet (x) \bullet \sim(\phi x \bullet \psi x). \supset. (E2)_x \phi x. \vee. \psi x$$

Page 124

If ϕ and ψ here are of the form $x = a. \vee. x = b$, etc., then the whole proposition has become a contrivance for ensuring that we add correctly.

Page 124

In the symbolism there is an actual correlation, whereas at the level of meaning only the possibility of correlation is at issue.

Page 124

The problem is: How can we make preparations for the reception of something that may happen to exist?

Page 124

The axiom of infinity is nonsense if only because the possibility of expressing it would presuppose infinitely many things--i.e. what it is trying to assert. You can say of logical concepts such as that of infinity that their essence implies their existence.

Page 124

$$101. (3)_x \phi x \bullet (4)_x \psi x \bullet \sim(\exists x) \phi x. \psi x. \supset_{\phi\psi}. (3 + 4)_x \phi x. \vee. \psi x [\dagger 1]$$

Page 124

This expression isn't equivalent to the substitution rule $3 + 4 = 7$.

Page 124

We might also ask: Suppose I have four objects satisfying a function, does it always make sense to say that these 4 objects are 2 + 2 objects? I certainly don't know whether there are functions grouping them into 2 and 2. Does it make sense to say of 4 objects taken at random that they are composed of 2 objects and 2 objects?

Page Break 125

Page 125

The notation I used above ' $(3 + 4)_x$ ' etc. already contains the assumption that it always makes sense to

construe 7 as 3 + 4, since on the right hand side of the ' $\supset_{\phi\psi}$ ' ψ I have so to speak already forgotten where the 3 and 4 have come from. On the other hand: I can surely always distinguish 3 and 4 in the sign $1 + 1 + 1 + 1 + 1 + 1 + 1$.

Page 125

Perhaps this provides the answer? What would it be like for me to have a sign for 7 in which I couldn't separate 3 and 4? Is such a sign conceivable?

Page 125

Does it make sense to say a relation holds between 2 objects, although for the rest there is no concept under which they both fall?

Page 125

102 I want to say numbers can only be defined from propositional *forms*, independently of the question which propositions are true or false.

Page 125

Only 3 of the objects a, b, c, d have the property ϕ . That can be expressed through a disjunction. Obviously another case where a numerical assertion doesn't refer to a concept (although you could make it look as though it did by using an '='.)

Page 125

If I say: If there are 4 apples on the table, then there are $2 + 2$ on it, that only means that the 4 apples already contain the possibility of being grouped into two and two, and I needn't wait for them actually to be grouped by a concept. This 'possibility' refers to the sense, not the truth of a proposition. $2 + 2 = 4$ may mean 'whenever I have four objects, there is the possibility of grouping them into 2 and 2'.

Page 125

103 How am I to know that ||||| and ||||| are the *same* sign? It isn't enough that they look *alike*. For having roughly the same Gestalt can't be what is to constitute the identity of the signs, but just their being the same in number.

Page Break 126

Page 126

If you write (E ||||) etc. • (E |||||) etc. • \supset . (E |||||) --A [\dagger 1] you may be in doubt as to how I obtained the numerical sign in the right-hand bracket if I don't know that it is the result of adding the two left-hand signs. I believe that makes it clear that this expression is only an application of $5 + 7 = 12$ but doesn't represent this equation itself.

Page 126

If we ask: But what then does ' $5 + 7 = 12$ ' mean--what kind of significance or point is left for this expression--the answer is, this equation is a rule for signs which specifies which sign is the result of applying a particular operation (addition) to two other particular signs. The content of $5 + 7 = 12$ (supposing someone didn't know it) is precisely what children find difficult when they are learning this proposition in arithmetic lessons.

Page 126

We can completely disregard the special structure of the proposition A and pay attention solely to the relation, the connection, between the numerical signs in it. This shows that the relation holds independently of the proposition--i.e. of the other features of its structure which make it a tautology.

Page 126

For if I look at it as a tautology I merely perceive features of its structure and can now perceive the addition theorem *in* them, while disregarding other characteristics that are essential to it as a proposition.

Page 126

The addition theorem is in this way to be recognized in it (among other places), not *by means of* it.

Page 126

This thought would of course be nonsense if it were a question here of the *sense* of a proposition, and not of the way the structure of a tautology functions.

Page Break 127

Page 127

104 You could reply: what I perceive in the sign A and call the relation between the numerical signs is once more only the bringing together of extensions of concepts: I combine the first five strokes of the right-hand bracket, which stand in 1-1 correspondence with the five in one of the left-hand brackets, with the remaining 7 strokes, which stand in 1-1 correspondence with the seven in the other left-hand bracket, to make 12 strokes which do one or the other. But even if I followed this train of thought, the fundamental insight would still remain, that the 5 strokes and the 7 combine *precisely to make 12* (and so for example to make the same structure as do 4 and 4 and 4).--It is always only insight into the internal relations of the structures and not some proposition or other or some logical consideration which tells us this. And, as far as this insight is concerned, everything in the tautology apart from the numerical structures is mere decoration; they are all that matters for the arithmetical proposition. (Everything else belongs to the *application* of the arithmetical proposition.)

Page 127

Thus what I want to say is: it isn't what occasions our combining 5 and 7 that belongs to arithmetic, but the process of doing so and its outcome.

Page 127

Suppose I wrote out the proposition A but put the wrong number of strokes in the right-hand bracket, then you would and could only come upon this mistake by comparing the structures, not by applying theorems of logic.

If asked how do you know that this number of strokes in the right-hand bracket is correct, I can only justify it by a comparison of the structures.

In this way it would turn out that what Frege called the 'gingersnap standpoint' in arithmetic could yet have some justification.

105 And now--I believe--the relation between the extensional conception of classes and the concept of a number as a feature of a

logical structure is clear: an extension is a characteristic of the sense of a proposition.

106 Now if the transition in A were the only application of this arithmetical schema, wouldn't it then be possible or necessary to replace it or define it by the tautology?

That is to say, what would it be like for A to be the most general form of the application of the arithmetical schema?

If A were the only--and therefore *essentially* the only--application of the schema, then in the very nature of the case the schema couldn't mean anything other than just the tautology.

Or: the schema itself must then be the tautology and the tautology nothing other than the schema.

In that case, you also could no longer say A was an application of the schema-- A would be the schema, only not as it were the implement on its own, but the implement with its handle, without which it is after all useless.

What A contains apart from the schema can then only be what is necessary in order to apply it.

But nothing at all is necessary, since we understand and apply the propositions of arithmetic perfectly well without adding anything whatever to them.

But forming a tautology is especially out of place here, as we can see perfectly well from the tautology itself, since otherwise in order to recognise it as a tautology we should have to recognise yet another one as a tautology and so on [\dagger 1].

107 Arithmetical propositions, like the multiplication table and things of that kind, or again like definitions which do not have whole propositions standing on both sides, are used in *application* to propositions. And anyhow I certainly can't apply them to anything else. (Therefore I don't first need some description of their application.)

No investigation of concepts, only direct insight can tell us [\dagger 1] that $3 + 2 = 5$.

That is what makes us rebel against the idea that A could be the proposition $3 + 2 = 5$. For what enables us to tell that this expression is a tautology cannot itself be the result of an examination of concepts but must be immediately visible.

And if we say numbers are structures we mean that they must always be of a kind with what we use to represent them.

I mean: numbers are what I represent in my language by number schemata.

That is to say, I take (so to speak) the number schemata of the language as what I know, and say numbers are what these represent [\dagger 2].

This is what I once meant when I said, it is with the calculus [system of calculation] that numbers enter into logic.

Page 129

108 What I said earlier about the nature of arithmetical equations and about an equation's not being replaceable by a tautology explains--I believe--what Kant means when he insists that $7 + 5 = 12$ is not an analytic proposition, but synthetic *a priori*.

Page Break 130

Page 130

Am I using the same numbers when I count the horses in a stall and when I count the different species of animal in the stall? When I count the strokes in a line and the kinds of group (as defined by the different number of strokes)?

Page 130

Whether they are cardinal numbers in the same sense depends on whether the same syntactical rules hold for them.

Page 130

(It is conceivable that there should be no man in a room, but not that there should be a man of *no* race in it.)

Page 130

Arithmetic is the grammar of numbers. Kinds of number can only be distinguished by the arithmetical rules relating to them.

Page 130

109 One always has an aversion to giving arithmetic a foundation by saying something about its application. It appears firmly enough grounded in itself. And that of course derives from the fact that arithmetic is its own application.

Page 130

Arithmetic doesn't talk about numbers, it works with numbers.

Page 130

The calculus presupposes the calculus.

Page 130

Aren't the numbers a logical peculiarity of space and time?

Page 130

The calculus itself exists only in space and time.

Page 130

Every mathematical calculation is an application of itself and only as such does it have a sense. *That* is why it isn't necessary to speak about the general form of logical operation when giving a foundation to arithmetic.

Page 130

A cardinal number is applicable to the subject-predicate form, but not to every variety of this form. And the extent to which it is applicable simply characterizes the subject-predicate form.

Page 130

On the one hand it seems to me that you can develop arithmetic completely autonomously and its application takes care of itself,

Page Break 131

since wherever it's applicable we may also apply it. On the other hand a nebulous introduction of the concept of number by means of the general form of operation--such as I gave--can't be what's needed.

Page 131

You could say arithmetic is a kind of geometry; i.e. what in geometry are constructions on paper, in arithmetic are calculations (on paper).--You could say it is a more general kind of geometry.

Page 131

And can't I say that in this sense chess (or any other game) is also a kind of geometry.

Page 131

But in that case it must be possible to work out an *application* of chess that is completely analogous to that of arithmetic.

Page 131

You could say: Why bother to limit the application of arithmetic, that takes care of itself. (I can make a knife without bothering which sorts of material it will cut: that will show soon enough.)

wrong result? Of course not. And that of course means only that the computation was not an experiment.

Page 133

It might look as though the mathematical computation entitled us to make a prediction--say, that I could give 3 people their share and there will be two apples left over. But that isn't so. What justifies us in making this prediction is an hypothesis of physics, which lies outside the calculation. The calculation is only a study of logical forms, of structures, and of itself can't yield anything new.

Page 133

112 Different as strokes and court cases are, you can still use strokes to represent court cases on a calendar. And you can count the former instead of the latter.

Page 133

This isn't so, if, say, I want to count hat-sizes. It would be unnatural to represent three hat-sizes by three strokes. Just as if I were to represent a measurement, 3 ft, by 3 strokes. You can certainly do so, but then '|||' represents in a different way.

Page 133

If 3 strokes on paper are the sign for the number 3, then you can say the number 3 is to be applied in the way in which the 3 strokes can be applied.

Page 133

Of what 3 strokes are a picture, of that they can be used as a picture.

Page 133

113 The natural numbers are a form given in reality through things, as the rational numbers are through extensions etc. I mean, by actual forms. In the same way, the complex numbers are given by actual manifolds. (The *symbols* are actual.)

Page 133

What distinguishes a statement of number about the extension of a concept from one about the range of a variable? The first is a proposition, the second not. For the statement of number about

Page Break 134

a variable can be derived from the variable itself. (It must show itself.)

Page 134

But can't I specify a variable by saying that its values are to be all objects satisfying a certain material function? In that case the variable is not a form! And then the sense of one proposition depends on whether another is true or false.

Page 134

A statement of number about a variable consists in a transformation of the variable rendering the number of its values visible.

Page 134

114 What kind of proposition is 'There is a prime number between 5 and 8'? I would say 'That shows itself'. And that's correct, but can't you draw attention to this internal state of affairs? You could surely say: Search the interval between 10 and 20 for prime numbers. How many are there? Wouldn't that be a straightforward problem? And how would its result be correctly expressed or represented? What does the proposition 'There are 4 primes between 10 and 20' mean?

Page 134

This proposition seems to draw our attention to a particular aspect of the matter.

Page 134

If I ask someone, 'How many primes are there between 10 and 20?', he may reply, 'I don't know straight off, but I can work it out any time you like.' For it's as if there were somewhere where it was already written out.

Page 134

If you want to know what a proposition means, you can always ask 'How do I know that?' Do I know that there are 6 permutations of 3 elements in the same way in which I know there are 6 people in this room? No. Therefore the first proposition is of a different *kind* from the second.

Page 134

Another equally useful question is 'How would this proposition actually be used in practice?'; and there the proposition from the theory of combinations is of course used as a law of inference in the transition from one proposition to another, each of which describes a reality, not a *possibility*.

Page Break 135

Page 135

You can, I think, say in general that the use of apparent propositions about possibilities--and impossibilities--is always in the passage from one actual proposition to another.

Page 135

Thus I can, e.g., infer from the proposition 'I label 7 boxes with permutations of a, b, c ' that at least *one* of the labels is repeated.--And from the proposition 'I distribute 5 spoons among 4 cups' it follows that one cup gets 2 spoons, etc.

Page 135

If someone disagrees with us about the number of men in this room, saying there are 7, while we can only see 6, we can understand him even though we disagree with him. But if he says that for him there are 5 pure colours, in that case we don't understand him, or must suppose we completely misunderstand one another. This number is demarcated in dictionaries and grammars and not within language.

Page Break 136

XI

Page 136

115 A statement of number doesn't always contain something general or indefinite: 'The interval AB is divided into two (3, 4 etc.) equal parts.'

Page 136

There doesn't even need to be a certain element of generality in a statement of number.' Suppose, e.g., I say 'I see three equal circles equidistant from one another'.

Page 136

If I give a correct description of a visual field in which three red circles stand on a blue ground, it surely won't take the form of saying ' $(\exists x, y, z): x$ is circular and red and y is circular and red, etc. etc.'

Page 136

You might of course write it like this: there are 3 circles with the property of being red. But at this point the difference emerges between improper objects--colour patches in a visual field, sounds, etc. etc.--and the elements of knowledge, the genuine objects.

Page 136

It is plain that the proposition about the three circles isn't general or indefinite in the way a proposition of the form $(\exists x, y, z) \cdot \phi x \cdot \phi y \cdot \phi z$ is. That is, in such a case, you may say: Certainly I know that three things have the property ϕ , but I don't know *which*; and you can't say this in the case of three circles.

Page 136

'There are now 3 red circles of such and such a size and in such and such a place in my visual field' determines the facts completely and it would be nonsense to say I don't know *which* circles they are.

Page 136

Think of such 'objects' as: a flash of lightning, the simultaneous occurrence of two events, the point at which a line cuts a circle, etc.; the three circles in the visual field are an example for all these cases.

Page 136

You can of course treat the subject-predicate form (or, what comes to the same thing, the argument-function form) as a norm

Page Break 137

of representation, and then it is admittedly important and characteristic that whenever we use numbers, the number may be represented as the property of a predicate. Only we must be clear about the fact that now we are not dealing with objects and concepts as the results of an analysis, but with moulds into which we have squeezed the proposition. And of course it's significant that it can be fitted into this mould. But squeezing something into a mould is the opposite of analysis. (If you want to study the natural growth of an apple tree, you don't look at an espalier tree--except to see how *this* tree reacts to *this* pressure.)

Page 137

That implies the Fregean theory of number would be applicable provided we were not intending to give an analysis of propositions. This theory explains the concept of number for the idioms of everyday speech. Of course, Frege would have said (I remember a conversation we had) that the simultaneous occurrence of an eclipse of the moon and a court case was an object. And what's wrong with that? Only that we in that case use the word 'object' ambiguously, and so throw the results of the analysis into disarray.

Page 137

If I say, 'There are 4 men in this room', then at any rate a disjunction seems to be involved, since it isn't said *which* men. But this is quite inessential. We could imagine all men to be indistinguishable from one another apart

from their location (so that it would be a question of humanity at a particular place), and in that case all indefiniteness would vanish.

Page 137

116 If I am right, there is no such concept as 'pure colour'; the proposition 'A has a pure colour' simply means 'A is red, or yellow, or green, or blue'. 'This hat belongs to either A or B or C' isn't the same proposition as 'This hat belongs to someone in this room', even if as a matter of fact only A, B, and C are in the room, since that needs saying.--'There are two pure colours on this surface', *means* 'On this surface there is red and yellow, or red and blue, or red and green etc.'

Page 137

Even if I may not say 'There are four pure colours', still the pure colours and the number 4 are somehow connected, and that must

Page Break 138

come out in some way or other, e.g. if I say, 'I can see 4 colours on this surface: yellow, blue, red and green.'

Page 138

The situation must be exactly similar for permutations. The permutations (without repetition) of *AB* are *AB*, *BA*. They are not the extension of a concept: they alone are the concept. But in that case you cannot say of these that they are two. And yet apparently we do just that in the theory of combinations. It strikes me as a question of a correlation similar to the one between algebra and inductions in arithmetic. Or is the connection the same as that between geometry and arithmetic? The proposition that there are two permutations of *AB* is in fact completely on all fours with the proposition that a line meets a circle in 2 points. Or, that a quadratic equation has two roots.

Page 138

If we say that *AB* admits of two permutations, it sounds as though we had made a *general* assertion, analogous with 'There are two men in the room', in which nothing further is said or need be known about the men. But this isn't so in the *AB* case. I cannot give a more general description of *AB*, *BA*, and so the proposition that two permutations are possible cannot say any less than that the permutations *AB*, *BA* are possible. To say that 6 permutations of 3 elements are possible cannot say less, i.e. anything more general, than is shown by the schema:

ABC
ACB
BAC
BCA
CAB
CBA

For it's *impossible* to know the number of possible permutations without knowing which they are. And if this weren't so, the theory of combinations wouldn't be capable of arriving at its general formulae. The law which we see in the formulation of the permutations is represented by the equation $p = n!$ In the same sense, I believe, as that in which a circle is given by its equation.

--Of course, I can correlate the number 2 with the permutations *AB*, *BA*, just as I can 6 with the complete set of permutations of *A*, *B*, *C*, but this doesn't give me the theorem of combination

Page Break 139

theory--What I see in *AB*, *BA* is an internal relation which therefore cannot be described.--That is, *what* cannot be described is that which makes this class of permutations complete.--I can only count what is actually there, not possibilities. But I can, e.g., work out how many rows a man must write if in each row he puts a permutation of 3 elements and goes on until he can't go any further without repetition. And this means he needs 6 rows to write down the permutations *ABC*, *ACB*, etc. since these just are '*the* permutations of *A*, *B*, *C*'. But it makes no sense to say that these are all the permutations of *A*, *B*, *C*.

Page 139

117 We could imagine a combination computer exactly like the Russian abacus.

Page 139

It is clear that there is a mathematical question: 'How many permutations of--say--4 elements are there?', a question of precisely the same kind as 'What is 25×18 ?'. For in both cases there is a general method of solution.

Page 139

But still it is only with respect to this method that this question exists.

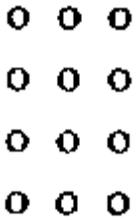

Page 139

The proposition that there are 6 permutations of 3 elements is identical with the permutation schema, and thus there isn't here a proposition, 'There are 7 permutations of 3 elements', for no such schema corresponds to it.

You may also say that the proposition 'There are 6 permutations of 3 elements' is related to the proposition 'There are 6 people in this room' in precisely the same way as is '3 + 3 = 6', which you could also cast in the form 'There are 6 units in 3 + 3'. And just as in the one case I can count the rows in the permutation schema, so in the

other I can count the strokes in .

Just as I can prove that $4 \times 3 = 12$ by means of the schema:

I can also prove $3! = 6$ by means of the permutation schema.

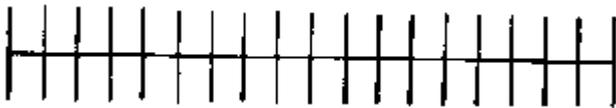

118 What is meant by saying I have as many spoons as *can* be put in 1-1 correspondence with a dozen bowls?

Either this proposition assumes I have 12 spoons, in which case I can't say that they can be correlated with the 12 bowls, since the opposite would be impossible; or else it doesn't assume I have 12 spoons, in which case it says I *can* have 12 spoons, and that's self-evident and once more cannot be said.

You could also ask: does this proposition say any *less* than that I have 12 spoons? Does it say something which only together with another proposition implies that I have 12 spoons? If p follows q alone, then q already says p . An apparent process of thought, making the transition, doesn't come in.

The symbol for a class is a list.

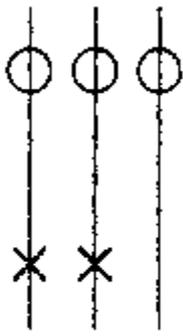

Can I know there are as many apples as pears on this plate, without knowing how many? And what is meant by not knowing how many? And how can I find out how many? Surely by counting. It is obvious that you can discover that there are the same number by correlation, without counting the classes.

In Russell's theory only an *actual* correlation can show the 'similarity' of two classes. Not the *possibility* of correlation, for this consists precisely in the numerical equality. Indeed, the possibility must be an *internal* relation between the extensions of the concepts, but this internal relation is only given through the equality of the 2 numbers.

A cardinal number is an internal property of a list.

119 We divide the evidence for the occurrence of a physical event according to the various kinds of such evidence, into the heard, seen, measured etc., and see that in each of these taken singly there is a formal element of order, which we can call space.

Page 141

What sort of an *impossibility* is the impossibility, e.g., of a 1-1 correlation between 3 circles and 2 crosses? We could also ask--and it would obviously be a question of the same sort--what sort of an impossibility is the impossibility of making a correlation by drawing parallel lines, if the arrangement is the given one?

Page 141

That a 1-1 correlation is possible is shown in that a significant proposition--true or false--asserts that it obtains. And that the correlation discussed above is not possible is shown by the fact that we cannot describe it.

Page 141

We can say that there are 2 circles in this square, even if in reality there are 3, and this proposition is simply false. But I cannot say that this group of circles is comprised of 2 circles, and just as little that it's comprised of 3 circles, since I should then be ascribing an *internal* property.

Page 141

It is nonsense to say of an extension that it has such and such a number, since the number is an *internal* property of the extension. But you can ascribe a number to the concept that collects the extension (just as you can say that this extension satisfies the concept).

Page 141

120 It is remarkable that in the case of a tautology or contradiction you actually could speak of sense and reference in Frege's sense.

Page 141

If we call its property of being a tautology the reference of a tautology, then we may call the way in which the tautology comes about here the sense of the tautology. And so for contradiction.

Page 141

If, as Ramsey proposed, the sign '=' were explained by saying that $x = x$ is a tautology, and $x = y$ a contradiction, then we may say that the tautology and the contradiction have no 'sense' here.

Page Break 142

Page 142

So, if a tautology shows something through the fact that just *this* sense gives *this* reference, then a tautology à la Ramsey shows nothing, since it is a tautology by definition.

Page 142

What then is the relation between the sign '**Def** = ' and the equals sign explained by means of tautology and contradiction?

Page 142

Is ' $p \cdot q = \sim(\sim p \vee \sim q)$ ' a tautology for the latter? You could say ' $p \cdot q = p \cdot q$ ' is taut., and since according to the definition you may substitute ' $\sim(\sim p \vee \sim q)$ ' for one of the signs ' $p \cdot q$ ', the previous expression is also a tautology.

Page 142

Hence you should not write the explanation of the equals sign thus:

$x = x$ is taut.
 $x = y$ is contra.

but must say: if, and *only* if, 'x' and 'y' have the same reference according to the sign-rules, then ' $x = y$ ' is taut: if 'x' and 'y' do not have the same reference according to the sign-rules, then ' $x = y$ ' is contra. In that case it would be to the point to write the equals sign thus defined differently, to distinguish it from ' $x = y$ ', which represents a rule for signs and says that we may substitute y for x. That is just what I cannot gather from the sign as explained above, but only from the fact that it is a tautology, but I don't know that either unless I already know the rules of substitution.

Page 142

It seems to me that you may compare mathematical equations only with significant propositions, not with

tautologies. For an equation contains precisely this assertoric element--the equals sign--which is not designed for showing something. Since whatever shows itself, shows itself without the equals sign. The equals sign doesn't correspond to the ' \supset .' in ' $p \bullet (p \supset q) \supset q$.' since the ' \supset .' is only *one* element among others which go to make up the tautology. It doesn't drop out of its context, but belongs to the proposition, in the same way that the ' \bullet ' or ' \supset ' do. But the '=' is a copula, which alone makes the equation into something

Page Break 143

propositional. A tautology shows something, an equation shows nothing: rather, it indicates that its sides show something.

Page 143

121 An equation is a rule of syntax.

Page 143

Doesn't that explain why we cannot have questions in mathematics that are in principle unanswerable? For if the rules of syntax cannot be grasped, they're of no use at all. And equally, it explains why an infinity that transcends our powers of comprehension cannot enter into these rules. And it also makes intelligible the attempts of the formalists to see mathematics as a game with signs.

Page 143

You may certainly construe sign-rules, for example definitions, as propositions about signs, but you don't *have to* treat them as propositions at all. They belong to the devices of language. Devices of a different kind from the propositions of language.

Page 143

Ramsey's theory of identity makes the mistake that would be made by someone who said that you could use a painting as a mirror as well, even if only for a single posture. If we say this, we overlook that what is essential to a mirror is precisely that you can infer from it the posture of a body in front of it, whereas in the case of the painting you have to know that the postures tally before you can construe the picture as a mirror image.

Page 143

Weyl's [\dagger 1] 'heterological' paradox:

$$\begin{array}{l} \text{Def} \qquad \qquad \qquad \text{Def} \\ \sim \phi (' \phi ') = ' \phi ' \text{ is heterological} = F (' \phi ') \\ F (' F ') = \sim F (' F ') = \sim [\sim (\hat{\phi} (' \hat{\phi} ')) (\sim (\hat{\phi} (' \hat{\phi} ')))] \end{array}$$

Page 143

122 We may imagine a mathematical proposition as a creature which itself knows whether it is true or false. (In contrast with genuine propositions.)

Page 143

A mathematical proposition itself knows that it is true or that it

Page Break 144

is false. If it is about all the numbers, it must also survey all the numbers.

Page 144

Its truth or falsity must be contained in it, as is its sense.

Page 144

It's as though the generality of such a proposition as ' $(n) \sim \text{Chr } n$ ' were only a pointer to the genuine, actual, mathematical generality of a proposition [\dagger 1]. As though it were only a description of the generality, not the generality itself. As if the proposition formed a sign only in a purely external way and you still needed to give the sign a sense from within.

Page 144

We feel the generality possessed by the mathematical assertion to be different from the generality of the proposition proved.

Page Break 145

Page 145

How is a mathematical problem related to its solution?

Page 145

We could say: a mathematical proposition is an allusion to a proof.

Page 145

A generalization cannot be both empirical and provable.

Page 145

If a proposition is to have a definite sense (and it's nonsense otherwise), it must comprehend--survey--its sense completely; a generalization only makes sense if it--i.e. all values of its variables--is completely determined.

Page Break 146

XII

Page 146

123 If, by making a series of tests, I advance along an endless stretch, why should it be any different in the case of an infinite one? And in that case of course, I can never get to the end.

Page 146

But if I only advance along the infinite stretch step by step, then I can't grasp the infinite stretch at all.

Page 146

So I grasp it in a different way; and if I have grasped it, then a proposition about it can only be verified in the way in which the proposition has taken it.

Page 146

So now it can't be verified by putative endless striding, since even such striding wouldn't reach a goal, since of course the proposition can outstrip our stride just as endlessly as before. No: it can only be verified by *one* stride, just as we can only grasp the totality of numbers at *one* stroke.

Page 146

We may also say: there is no path to infinity, *not even an endless one*.

Page 146

The situation would be something like this: We have an infinitely long row of trees, and so as to inspect them, I make a path beside them. All right, the path must be endless. But if it is endless, then that means precisely that you can't walk to the end of it. That is, it does *not* put me in a position to survey the row. (*Ex hypothesi* not.)

Page 146

That is to say, the endless path doesn't have an end 'infinitely far away', it has no end.

Page 146

124 It isn't just impossible 'for us men' to run through the natural numbers one by one; it's *impossible*, it means nothing.

Page 146

Nor can you say, 'A proposition cannot deal with all the numbers

Page Break 147

one by one, so it has to deal with them by means of the concept of number', as if this were a *pis aller*: 'Because we can't do it *like this*, we have to do it another way.' But it's not like that: of course it's possible to deal with the numbers one by one, but that *doesn't* lead to the totality. For the totality is only given as a concept.

Page 147

If it's objected that 'if I run through the number series I either eventually come to the number with the required property, or I never do', we need only reply that it makes no sense to say that you *eventually* come to the number and *just as little* that you *never* do. Certainly it's correct to say 101 is or is not the number in question. But you can't talk about *all* numbers, because there's no such thing as *all* numbers.

Page 147

125 Can you say you couldn't foresee that $6 - 4$ would be precisely 2, but only see it when you get there?

Page 147

That, in the case of the logical concept $(1, \xi, \xi + 1)$, the existence of its objects is already given with the concept, of itself shows that it determines them.

Page 147

Besides, it's quite clear that every number has its own irreducible individuality. And if I want to prove that a number has a certain property, in one way or another I must always bring in the number itself.

Page 147

In this sense you might say that the properties of a particular number cannot be *foreseen*. You can only see them when you've got there.

Page 147

Someone may say: Can't I prove something about the number 3^{10} , even though I can't write it down? Well, 3^{10} already is the number, only written in a different way.

What is fundamental is simply the repetition of an operation. Each stage of the repetition has its own individuality.

But it isn't as if I use the operation to move from one individual to another so that the operation would be the means for getting from one to the other--like a vehicle stopping at every number

which we can then study: no, applying the operation $+ 1$ three times yields and *is* the number 3.

An 'infinitely complicated law' means no law at all. How are you to know it's infinitely complicated? Only by there being as it were infinitely many approximations to the law. But doesn't that imply that they in fact *approach* a limit? Or could the infinitely many descriptions of intervals of the prime number series be called such approximations to a law? No, since no description of a finite interval takes us any nearer the goal of a complete description.

Then how would an infinitely complicated law in this sense differ from no law at all?

In that case, the law would, at best, run 'Everything is as it is'.

126 Yet it still looks now as if the quantifiers make no sense for numbers. I mean: you can't say ' $(n) \cdot \phi n$ ', precisely because 'all natural numbers' isn't a bounded concept. But then neither should one say a general proposition follows from a proposition about the nature of number.

But in that case it seems to me that we can't use generality--all, etc.--in mathematics at all. There's no such thing as 'all numbers', simply because there are infinitely many. And because it isn't a question here of the amorphous 'all', such as occurs in 'All the apples are ripe', where the set is given by an external description: it's a question of a collection of structures, which must be given precisely as such.

It's, so to speak, no business of logic how many apples there are when we talk of all the apples. Whereas it's different in the case of the numbers: there, it has an individual responsibility for each one of them.

127 What is the meaning of such a mathematical proposition as ' $(\exists n) \cdot 4 + n = 7$ '? It might be a disjunction - $4 + 0 = 7 \cdot \vee \cdot 4 + 1 = 7 \cdot \vee \cdot 4 + 2 = 7 \cdot \vee \cdot$ etc. *ad inf.* But what does that mean? I can

understand a proposition with a beginning and an end. But can one also understand a proposition with no end? [\dagger 1]

I also find it intelligible that one can give an infinite rule by means of which you may form infinitely many finite propositions. But what does an endless proposition mean?

If no finite product makes a proposition true, that means no product makes it true. And so it *isn't* a logical product.

128 But then can't I say of an equation 'I know it doesn't hold for some substitution--I've forgotten now which; but whether it doesn't hold in general, I don't know'? Doesn't that make good sense, and isn't it compatible with the generality of the inequality?

Is the reply: 'If you know that the inequality holds for some substitution, that can never mean "for some (arbitrary) member of the infinite number series", but I always know too that this number lies between 1 and 10^7 , or within some such limits'?

Can I know that a number satisfies the equation without a finite section of the infinite series being marked out as one within which it occurs? No.

'Can God know all the places of the expansion of π ?' would have been a good question for the schoolmen to ask. In all such cases the answer runs, 'The question is senseless.'

'No degrees of brightness below this one hurt my eyes': that means, I have observed that my previous experiences correspond to a formal law.

129 A proposition about all propositions, or all functions, is *a priori* an impossibility: what such a proposition is intended to express would have to be shown by an induction. (For instance, that *all* propositions $\sim 2^n p$ say the same.) [†1]

This induction isn't itself a proposition, and that excludes there being any vicious circle.

What do we want to differentiate propositions from when we form the concept 'proposition'?

Isn't it the case that we can only give an external description of propositions in general?

Equally, if we ask: Is there a general form of law? As opposed to what? Laws must of course fill the whole of logical space, and so I can no longer mark them off.

Generality in arithmetic is indicated by an induction.
An induction is the expression for arithmetical generality.

Suppose one of the rules of a game ran 'Write down a fraction between 0 and 1'. Wouldn't we understand it? Do we need any limits here? And what about the rule 'Write down a number greater than 100'? Both seem thoroughly intelligible.

I have always said you can't speak of *all* numbers, because there's no such thing as 'all numbers'. But that's only the expression of a feeling. Strictly, one should say,... 'In arithmetic we never *are* talking about *all* numbers, and if someone nevertheless does speak in that way, then he so to speak invents something--nonsensical

--to supplement the arithmetical facts.' (Anything invented as a supplement to *logic* must of course be nonsense.)

130 It is difficult to extricate yourself completely from the extensional viewpoint: You keep thinking 'Yes, but there must still be an internal relation between $x^3 + y^3$ and z^3 , since the extension, if only I knew it, would have to show the result of such a relation.' Or perhaps: 'It must surely be either *essential* to *all n* to have the property or not, even if I can't know it.'

If I write ' $(\exists x) \bullet x^2 = 2x$ ', and don't construe the ' $(\exists x)$ ' extensionally, it can only mean: 'If I apply the rules for solving such an equation, I arrive at a particular number, in contrast with the cases in which I arrive at an identity or a prohibited equation.'

The defect (circle) in Dedekind's explanation of the concept of infinity lies in its application of the concept 'all' in the formal implication that holds independently if one may put it like this--of the question whether a finite or an infinite number of objects falls under its concepts. The explanation simply says: if the one holds of an object, so does the other. It does not consider the totality of objects at all, it only says something about the object at the moment in front of it, and *its application* is finite or infinite as the case may be.

But how are we to know such a proposition?--How is it verified? What really corresponds to what we mean isn't a proposition at all, it's the *inference* from ϕx to ψx , if this inference is permitted--but the inference isn't expressed by a proposition.

What does it mean to say a line can be extended indefinitely? Isn't this a case of an 'and so on *ad inf.*' that is quite different from that in mathematical induction? According to what's gone before, the expression for the possibility of extending it further would exist in the sense of a description of the extended line or of the act

of extending it. Now at first this doesn't seem to be connected with numbers at all. I can imagine the pencil drawing the line going on moving and keeping on for ever. But is it also conceivable that there should be no possibility of accompanying this process with a countable process? I think not.

131 The generality of a Euclidean proof. We say, the demonstration is carried out for *one* triangle, but the proof holds for all triangles--or for an arbitrary triangle. First, it's strange that what holds for one triangle should therefore hold for every other. It wouldn't be possible for a doctor to examine *one* man and then conclude that what he had found in his case must also be true of every other. And if I now measure the angles of a triangle and add them, I can't in fact conclude that the sum of the angles in every other triangle will be the same. It is clear that the Euclidean proof can say nothing about a totality of triangles. A proof can't go beyond itself.

But once more the construction of the proof is not an experiment, and were it so, its outcome couldn't prove anything for other cases. That is why it isn't even necessary for the construction actually to be carried out with pencil and paper, but a description of the construction must be sufficient to show all that is essential. (The description of an experiment isn't enough to give us the result of the experiment: it must actually be performed.) The construction in a Euclidean proof is precisely analogous to the proof that $2 + 2 = 4$ by means of the Russian abacus.

And isn't this the kind of generality the tautologies of logic have, which are demonstrated for p, q, r , etc.?

The essential point in all these cases is that what is demonstrated can't be expressed by a proposition.

132 If I say 'The world will *eventually* come to an end' then that means nothing at all if the date is left indefinitely open. For it's compatible with this statement that the world should still exist on any day you care to mention.--What is *infinite* is the *possibility* of numbers in propositions of the form 'In n days the world will come to an end'.

To understand the sense of a question, consider what an answer to it would look like.

To the question 'Is A my ancestor?' the only answers I can imagine are 'A is to be found in my ancestral gallery' or 'A is not to be found in my ancestral gallery' (Where by my ancestral gallery I understand the sum total of all kinds of information about my predecessors). But in that case the question can't mean anything more than 'Is A to be found in my ancestral gallery?' (An ancestral gallery has an end: that is a proposition of syntax.) If a god were to reveal to me that A was my ancestor, but not at what remove, even this revelation could only mean to me that I shall find A among my ancestors if I search long enough; but since I shall search through N ancestors, the revelation must mean that A is one of those N.

If I ask how many 9s immediately succeed one another after 3.1415 in the development of π , meaning my question to refer to the extension, the answer runs either, that in the development of the extension up to the place last developed (the N th) we have gone beyond the series of 9s, or, that 9s succeed one another up to the N th place. But in this case the question cannot have a different sense from 'Are the first $N - 5$ places of π all 9s or not?'--But of course, that isn't the question which interests us.

133 In philosophy it's always a matter of the application of a series of utterly simple basic principles that any child knows, and the--enormous--difficulty is only one of applying these in the confusion our language creates. It's never a question of the latest

results of experiments with exotic fish or the most recent developments in mathematics. But the difficulty in applying the simple basic principles shakes our confidence in the principles themselves.

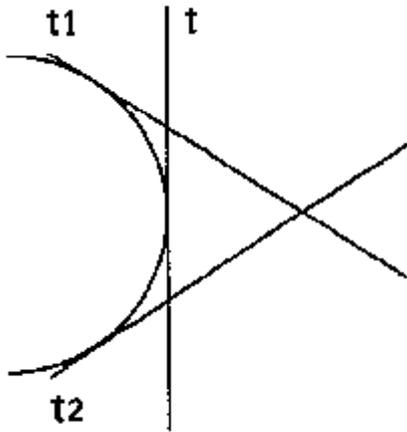

134 What sort of proposition is: 'On this strip you may see all shades of grey between black and white'? Here it looks at first glance as if we're talking about infinitely many shades.

Indeed we are apparently confronted here by the paradox that we can, of course, only distinguish a finite number of shades, and naturally the distinction between them isn't infinitely slight, and yet we see a continuous

transition.

Page 154

It is just as impossible to conceive of a particular grey as being one of the infinitely many greys between black and white as it is to conceive of a tangent t as being one of the infinitely many transitional stages in going from t_1 to t_2 . If I see a ruler roll from t_1 to t_2 , I see--if its motion is continuous--none of the individual intermediate positions in the sense in which I see t when the tangent is at rest; or else I see only a finite number of such positions.

Page 154

But if in such a case I appear to infer a particular case from a general proposition, then the general proposition is never derived from experience, and the proposition isn't a real proposition.

Page 154

If, e.g., I say 'I saw the ruler move from t_1 to t_2 , therefore I must have seen it at t ', this doesn't give us a valid logical inference. That is, if what I mean is that the ruler must have *appeared* to me at t --and so, if I'm talking about the position in visual space--then it doesn't in the least follow from the premiss. But if I'm talking about the physical ruler, then of course it's possible for the ruler to have skipped over

Page Break 155

position t , and yet for the phenomena in visual space to have remained continuous.

Page 155

135 Ramsey proposed to express the proposition that infinitely many objects satisfied a function by denying all propositions of the form:

$$\begin{aligned} &\sim(\exists x) \cdot \phi x \\ &(\exists x) \cdot \phi x \cdot \sim(\exists x, y) \cdot \phi x \cdot \phi y \\ &(\exists x, y) \cdot \phi x \cdot \phi y \cdot \sim(\exists x, y, z) \cdot \phi x \cdot \phi y \cdot \phi z, \text{ etc.} \end{aligned}$$

But let's suppose there are only three objects, i.e., there are only three names with a meaning. Then we can no longer write down the fourth proposition of the series, since it makes no sense to write: $(\exists x, y, z, u) \cdot \phi x \cdot \phi y \cdot \phi z \cdot \phi u$. So I don't arrive at the infinite by denying all the propositions in this series.

Page 155

'We only know the infinite by description.' Well then, there's just the description and nothing else.

Page 155

136 To what extent does a notation for the infinite presuppose infinite space or infinite time?

Page 155

Of course it doesn't presuppose an infinitely large sheet of paper. But how about the possibility of one?

Page 155

We can surely imagine a notation which extends through time, not space. Such as speech. Here too we clearly find it possible to imagine a representation of infinity, yet in doing so we certainly don't make any *hypothesis* about time. Time appears to us to be essentially an *infinite* possibility.

Page 155

Indeed, obviously infinite from what we know of its structure.

Page 155

Surely it's impossible that mathematics should depend on an hypothesis concerning physical space. And surely in this sense *visual space* isn't infinite.

Page 155

And if it's a matter, not of the reality, but of the possibility of the hypothesis of infinite space, then this

possibility must surely be prefigured somewhere.

Page Break 156

Page 156

Here we run into the problem that also arises for the extension of visual space that of the smallest visible distinction. The existence of a smallest visible distinction conflicts with continuity, and yet the two must be reconcilable with one another.

Page 156

137 If I have a series of alternately black and white patches, as shown in the diagram

then by continual bisection, I will soon arrive at a limit where I'm no longer able to distinguish the black and white patches, that is, where I have the impression of a grey strip.

Page 156

But doesn't that imply that a strip in my visual field cannot be bisected indefinitely often? And yet I don't see a discontinuity and of course I wouldn't, since I could only see a discontinuity if I hadn't yet reached the limit of divisibility.

Page 156

This seems very paradoxical.

Page 156

But what about the continuity between the individual rows? Obviously we have a last but one row of distinguishable patches and then a last row of uniform grey; but could you tell from this last row that it was in fact obtained by bisecting the last but one? Obviously not. On the other hand, could you tell from the so-called last but one row that it can no longer be visibly bisected? It seems to me, just as little. In that case, there would be no last visibly bisected row!

Page 156

If I cannot visibly bisect the strip any further, I can't even *try* to, and so can't see the failure of such an attempt. (This is like the case of the limitlessness of visual space.)

Page 156

Obviously, the same would hold for distinctions between colours.

Page Break 157

Page 157

Continuity in our visual field consists in our not seeing discontinuity.

Page 157

138 But if I can always see only a finite number of things, divisions, colours, etc., than there just isn't an infinity at all; in no sense whatever. The feeling here is: if I am always able to see only so few, then there aren't any more. As if it were a case like this: if I can only see 4, then there aren't 100. But infinity doesn't have the role of a number here. It's perfectly true; if I can only see 4, there aren't 100, there aren't even 5. But there is the infinite possibility that isn't exhausted by a small number any more than by a large: and in fact just because it *isn't* itself a quantity.

Page 157

We all of course know what it means to say there is an infinite possibility and a finite reality, since we say space and time are infinite but we can always only see or live through finite bits of them. But from where, then, do I derive any knowledge of the infinite at all? In some sense or other, I must have two kinds of experience: one which is of the finite, and which cannot transcend the finite (the idea of such a transcendence is nonsense even on its own terms), and one of the infinite. And that's how it is. Experience as experience of the facts gives me the finite; the objects *contain* the infinite. Of course not as something rivalling finite experience, but in intension. Not as though I could see space as practically empty, with just a very small finite experience in it. But, I can see in space the possibility of any finite experience. That is, no experience could be too large for it or exhaust it: not of course

because we are acquainted with the dimensions of every experience and know space to be larger, but because we understand this as belonging to the essence of space.--We recognize this essential infinity of space in its smallest part.

Page 157

Where the nonsense starts is with our habit of thinking of a large number as closer to infinity than a small one.

Page 157

As I've said, the infinite doesn't rival the finite. The infinite is that whose essence is to exclude nothing finite.

Page Break 158

Page 158

The word 'nothing' occurs in this proposition and, once more, this should not be interpreted as the expression for an infinite disjunction, on the contrary, 'essentially' and 'nothing' belong together. It's no wonder that time and again I can only explain infinity in terms of itself, i.e. *cannot explain* it.

Page 158

Space has no extension, only spatial objects are extended, but infinity is a property of space.

Page 158

(This of itself shows it isn't an infinite extent.)

Page 158

And the same goes for time.

Page 158

139 How about infinite divisibility? Let's remember that there's a point to saying we can conceive of *any* finite number of parts but not of an infinite number; but that this is precisely what constitutes infinite divisibility.

Page 158

Now, 'any' doesn't mean here that we can conceive of the *sum total* of *all* divisions (which we can't, for there's no such thing). But that there is the *variable* 'divisibility' (i.e. the concept of divisibility) which *sets no limit* to actual divisibility; and that constitutes its infinity.

Page 158

But how do we construct an infinite hypothesis, such as that there are infinitely many fixed stars (it's clear that *in the end* only a finite reality can correspond to it)? Once more it can only be given through a law. Let's think of an infinite series of red spheres.--Let's think of an infinite film strip. (It would give the possibility of everything finite that happens on the screen.) This is a typical case of an hypothesis reaching out to infinity. It's clear to us that no experience *corresponds* with it. It only exists in 'the second system', that is, in language; but how is it expressed there? (If a man can *imagine* an infinite strip, then as far as he's concerned there is an infinite reality, and also the 'actual infinite' of mathematics.) It is expressed by a proposition of the form '(n): ($\exists nx$). ϕx '. Everything relating to the infinite possibility (every infinite assertion about the

Page Break 159

film), is reproduced in the expression in the first bracket, and the reality corresponding to it in the second.

Page 159

But what then has divisibility to do with actual division, if something can be divisible that *never is* divided?

Page 159

Indeed, what does divisibility mean at all in the case of that which is given as primary? How can you distinguish between reality and possibility here?

Page 159

It must be wrong to speak as I do of restricting infinite possibility to what is finite.

Page 159

For it makes it look as if an infinite reality were conceivable even if there isn't one and so once more as though it were a question of a possible infinite extension and an actual finite one: as though infinite possibility were the possibility of an infinite number.

Page 159

And that again shows we are dealing with two different meanings of the word 'possible' when we say 'The line can be divided into 3 parts' and when we say 'The line can be divided infinitely often'. (This is also indicated by the proposition above, which questions whether there are actual and possible in visual space.)

Page 159

What does it mean to say a patch in visual space can be divided into three parts? Surely it can mean only that a proposition describing a patch divided in this way makes sense. (Provided it isn't a question of a confusion

between the divisibility of physical objects and that of a visual patch.)

Page 159

Whereas infinite--or better *unlimited*--divisibility doesn't mean there's a proposition describing a line divided into infinitely many parts, since there isn't such a proposition. Therefore this possibility is not brought out by any reality of the signs, but by a possibility of a *different* kind in the signs themselves.

Page 159

If you say space is infinitely divisible, then strictly speaking that means: space isn't made up of individual things (parts).

Page 159

In a certain sense, infinite divisibility means that space is indivisible, that *it* is not affected by any division. That it is above such

Page Break 160

things: *it* doesn't consist of parts. Much as if it were saying to reality: you may do what you like in me (you can be divided as often as you like in me.)

Page 160

Space gives to reality an infinite opportunity for division.

Page 160

And that is why there is only *one* letter in the first bracket. Obviously only an opportunity, nothing more.

Page 160

140 Is primary time infinite? That is, is it an infinite possibility? Even if it is only filled out as far as memory extends, that in no way implies that it is finite. It is infinite in the same sense as the three-dimensional space of sight and movement is infinite, even if in fact I can only see as far as the walls of my room. For what I see presupposes the possibility of seeing further. That is to say, I could correctly represent what I see only by an infinite form.

Page 160

Is it possible to imagine time with an end, or with two ends?

Page 160

What can happen *now*, could also have happened earlier, and could always happen in the future if time remains as it is. But *that* doesn't depend on a future experience. Time contains the possibility of all the future *now*.

Page 160

But all that of itself implies that time isn't infinite in the sense of the primitive conception of an infinite set.

Page 160

And so for space. If I say that I can imagine a cylinder extended to infinity, that is already contained in its nature. So again, contained in the nature of the homogeneity of the cylinder and of the space in which it is--and the one of course presupposes the other and this homogeneity is in the finite bit that I see.

Page 160

The space of human movement is infinite in the same way as time.

Page 160

141 The rules for a number-system--say, the decimal system--

Page Break 161

contain everything that is infinite about the numbers. That, e.g. *these rules* set no limits on the left or right hand to the numerals; *this* is what contains the expression of infinity.

Page 161

Someone might perhaps say: True, but the numerals are still limited by their use and by writing materials and other factors. That is so, but that isn't expressed in the *rules* for their use, and it is only in these that their real essence is expressed.

Page 161

Does the relation $m = 2n$ correlate the class of all numbers with one of its subclasses? No. It correlates any arbitrary number with another, and in that way we arrive at infinitely many pairs of classes, of which one is correlated with the other, but which are *never* related as class and subclass. Neither is this infinite process itself in some sense or other such a pair of classes.

Page 161

In the superstition that $m = 2n$ correlates a class with its subclass, we merely have yet another case of ambiguous grammar.

Page 161

What's more, it all hangs on the syntax of reality and possibility. $m = 2n$ contains the *possibility of*

correlating any number with another, but doesn't correlate all numbers with others.

Page 161

The word 'possibility' is of course misleading, since someone will say, let what is possible now become actual. And in thinking this, we always think of a temporal process and infer from the fact that mathematics has nothing to do with time, that in its case possibility is (already) actuality.

Page 161

(But in truth the opposite is the case, and what is called possibility in mathematics is precisely the same as it is in the case of time.)

Page 161

$m = 2n$ points along the number series, and if we add 'to infinity', that simply means that it doesn't point at an object a definite distance away.

Page Break 162

Page 162

142 The infinite number series is itself only such a possibility as emerges clearly from the single symbol for it '(1, x , $x + 1$)' [†1]. This symbol is itself an arrow with the first '1' as the tail of the arrow and ' $x + 1$ ' as its tip and what is characteristic is that just as length is inessential in an arrow--the variable x shows here that it is immaterial how far the tip is from the tail.

Page 162

It is possible to speak of things which lie in the direction of the arrow but nonsense to speak of all possible positions for things lying in the direction of the arrow as an equivalent for this direction itself.

Page 162

A searchlight sends out light into infinite space and so illuminates everything in its direction, but you can't say it illuminates infinity.

Page 162

You could also put it like this: it makes sense to say there can be infinitely many objects in a direction, but no sense to say there are infinitely many. And this conflicts with the way the word 'can' is normally used. For, if it makes sense to say a book can lie on this table, it also makes sense to say it is lying there. But here we are led astray by language. The 'infinitely many' is so to speak used adverbially and is to be understood accordingly.

Page 162

That is to say, the propositions 'Three things can lie in this direction' and 'Infinitely many things can lie in this direction' are only apparently formed in the same way, but are in fact different in structure: the 'infinitely many' of the second proposition doesn't play the same role as the 'three' of the first.

Page 162

It is, again, only the ambiguity of our language that makes it appear as if numerals and the word 'infinite' are both given as answers to the same question. Whereas the questions which have these words as an answer are in reality fundamentally different.

Page Break 163

Page 163

(The usual conception really amounts to the idea that the absence of a limit is itself a limit. Even if it isn't put as baldly as that.)

Page 163

If two arrows point in the same direction, isn't it in such a case absurd to call these directions equally long because whatever lies in the direction of the one arrow, also lies in that of the other?

Page 163

Generality in mathematics is a direction, an arrow pointing along the series generated by an operation. And you can even say that the arrow points to infinity; but does that mean that there is something--infinity--at which it points, as at a thing? Construed in that way, it must of course lead to endless nonsense.

Page 163

It's as though the arrow designates the possibility of a position in its direction.

Page 163

143 In what sense is endless time a possibility and not a reality? For someone might object to what I am saying by arguing that time must be just as much a reality as, say, colour.

Page 163

But isn't colour taken by itself also only a possibility, until it is in a particular time and place? Empty infinite

time is only the possibility of facts which alone are the realities.

Page 163

But isn't the infinite *past* to be thought of as filled out, and doesn't that yield an infinite reality?

Page 163

And if there is an infinite reality, then there is also contingency in the infinite. And so, for instance, also an infinite decimal that isn't given by a law. Everything in Ramsey's conception stands or falls with that.

Page 163

That we don't think of time as an infinite reality, but as infinite in intension, is shown in the fact that on the one hand we can't imagine an infinite time interval, and yet see that no day can be the last, and so that time cannot have an end.

Page Break 164

Page 164

We might also say: infinity lies in the nature of time, it isn't the extension it happens to have.

Page 164

We are of course only familiar with time--as it were--from the bit of time before our eyes. It would be extraordinary if we could grasp its infinite extent in this way (in the sense, that is to say, in which we could grasp it if we ourselves were its contemporaries for an infinite time.)

Page 164

We are in fact in the same position with time as with space. The actual time we are acquainted with is limited (finite). Infinity is an internal quality of the form of time.

Page 164

144 The infinite number series is only the infinite possibility of finite series of numbers. It is senseless to speak of the *whole* infinite number series, as if it, too, were an extension.

Page 164

Infinite possibility is represented by infinite possibility. The signs themselves only contain the possibility and not the reality of their repetition [\dagger 1].

Page 164

Doesn't it come to this: the facts are finite, the infinite possibility of facts lies in the objects. That is why it is shown, not described.

Page 164

Corresponding to this is the fact that numbers--which of course are used to describe the facts--are finite, whereas their possibility, which corresponds with the *possibility* of facts, is infinite. It finds expression, as I've said, in the possibilities of the symbolism.

Page 164

The feeling is that there can't be possibility and actuality in mathematics. It's all on *one* level. And is, in a certain sense, actual.

Page Break 165

Page 165

And that is correct. For what mathematics expresses with its signs is all on *one* level; i.e. it doesn't speak sometimes about their possibility, and sometimes about their actuality. No, it can't even try to speak about their possibility. On the other hand, there is a possibility in its signs, i.e. the possibility found in genuine propositions, in which mathematics is applied.

Page 165

And when (as in set theory) it tries to *express* their possibility, i.e. when it confuses them with their reality, we ought to cut it down to size.

Page 165

We reflect far too little on the fact that a sign really cannot mean more than it is.

Page 165

The infinite possibility in the symbol relates--i.e. refers--only to the essence of a finite extension, and this is its way of leaving its size open.

Page 165

If I were to say, 'If we were acquainted with an infinite extension, then it would be all right to talk of an actual infinite', that would really be like saying, 'If there were a sense of abracadabra then it would be all right to talk about abracadabraic sense-perception'.

We see a continuous colour transition and a continuous movement, but in that case we just see *no* parts, *no* leaps (not infinitely many).

145 What is an infinite decimal not given by a rule? Can you give an infinite sequence of digits by a non-mathematical--and so external--description, instead of a law? (Very strange that there should be two modes of comprehension.)

'The number that is the result when a man endlessly throws a die', appears to be nonsense because no infinite number results from it.

But why is it easier to imagine life without end than an endless series in space? Somehow, it's because we simply take the endless

life as never complete, whereas the infinite series in space ought, we feel, already to exist as a whole.

Let's imagine a man whose life goes back for an infinite time and who says to us: 'I'm just writing down the last digit of π , and it's a 2'. Every day of his life he has written down a digit, without ever having begun; he has just finished.

This seems utter nonsense, and a *reductio ad absurdum* of the concept of an infinite *totality*.

Suppose we travel out along a straight line in Euclidean Space and say that at 10 m intervals we encounter an iron sphere of a certain diameter, *ad infinitum*; is this a construction? It seems so. What is strange is that you can construe such an infinite complex of spheres as the endless repetition of the same sphere in accordance with a certain law--and yet the moment you think of these spheres as each having its own individual characteristics, their infinite number seems to become nonsense.

Let's imagine an infinite row of trees, all of different heights between 3 and 4 yards. If there is a law governing the way the heights vary, then the series is defined and can be imagined by means of this law (this is assuming that the trees are indistinguishable save in their height). But what if the heights vary at random? Then--we're forced to say--there's only an infinitely long, an endless description. But surely that's not a description! I can suppose there to be infinitely many descriptions of the infinitely many finite stretches of the infinite row of trees, but in that case I have to know these infinitely many descriptions by means of a law governing their sequence. Or, if there's no such law, I once more require an infinite description of these descriptions. And that would again get me nowhere.

Now I could of course say that I'm aware of the law that each tree must differ in height from all its predecessors. It's true that this

is a law, but still not such as to define the series. If I now assume there could be a random series, then that is a series about which, by its very nature, nothing can be known apart from the fact that I can't know it. Or better, that it can't be known. For is this a situation in which 'the human intellect is inadequate, but a higher might succeed'? How then does it come about that human understanding frames this question at all, sets out on this path whose end is out of its reach?

What is infinite about endlessness is only the endlessness itself.

146 What gives the multiplicative axiom its plausibility? Surely that in the case of a finite class of classes we can in fact make a selection [choice]. But what about the case of infinitely many subclasses? It's obvious that in such a case I can only know the law for making a selection.

Now I can make something like a *random* selection from a finite class of classes. But is that *conceivable* in the case of an infinite class of classes? It seems to me to be nonsense.

Let's imagine someone living an endless life and making successive choices of an arbitrary fraction from the fractions between 1 and 2, 2 and 3, etc. *ad. inf.* Does that yield us a selection from all those intervals? No, since he does *not* finish. But can't I say nonetheless that all those intervals must turn up, since I can't cite any which he wouldn't *eventually* arrive at? But from the fact that given *any* interval, he will *eventually* arrive at it, it doesn't follow that he will *eventually* have arrived at them all.

Page 167

But doesn't this still give the description of a process that generates selections without end, and doesn't that mean precisely that an endless selection is formed? But here the infinity is only in the rule.

Page 167

Imagine the following hypothesis: there is in space an infinite series of red spheres, each one metre behind its predecessor. What

Page Break 168

conceivable experience could correspond to this hypothesis? I think for instance of my travelling along this series and every day passing a certain number, *n*, of red spheres. In that case, my experience ought to consist in the fact that on *every possible* day in the future I see *n* more spheres. But when shall I have had this experience? Never!

Page 168

147 You can only answer the objection 'But if nevertheless there were infinitely many things?' by saying 'But there aren't'. And what makes us think that perhaps there are is only our confusing the things of physics with the elements of knowledge [†1].

Page 168

For this reason we also can't suppose an hypothetical infinite visual space in which an infinite series of red patches is visible.

Page 168

What we imagine in physical space is not that which is primary, which we can know only to a greater or lesser extent; rather, what we can know of physical space shows us how far what is primary reaches and how we have to *interpret* physical space.

Page 168

But how is a proposition of the form 'The red patch *a* lies somewhere between *b* and *c*' to be analysed? This doesn't mean: 'The

patch *a* corresponds to one of the infinitely many numbers lying between the numbers of *b* and *c*' (it isn't a question of a disjunction). It's clear that the infinite possibility of positions of *a* between *b* and *c* isn't expressed in the proposition. Just as, in the case of 'I have locked him in the room', the infinitely many possible positions

Page Break 169

of the man shut in the room play no role whatever.

Page 169

'Each thing has one and only one predecessor; a has no successor; everything except for a has one and only one successor.' These propositions appear to describe an infinite series (and also to say that there are infinitely many things. But this would be a presupposition of the propositions' making sense). They appear to describe a *structure amorously*. We can sketch out a structure in accordance with these propositions, which they describe unambiguously. But where can we discover this structure in them?

Page 169

But couldn't we regard this set of propositions simply as propositions belonging to physics, setting out a scientific hypothesis? In that case they would have to be unassailable. But what would it be like if a biologist discovered a species of animal, in which *every* individual appeared to be the offspring of *one* earlier one, and put this forward as an hypothesis?

Page 169

Are we misled in such a case by the illusion that parcels of matter--i.e. in this case the members of a species of animal--were the simple objects?

Page 169

That is to say, isn't that which we can imagine multiplied to infinity never the things themselves, but combinations of the things in accordance with their infinite possibilities?

The things themselves are perhaps the four basic colours, space, time and other data of the same sort.

In that case, how about a series of fixed stars, in which *each* has a predecessor (in a particular spacial direction)? And this hypothesis would come out in the same way as that of an endless life. This seems to me to make sense, precisely because it doesn't conflict with the insight that we cannot make any hypothesis concerning the number of objects (elements of facts). Its analysis only presupposes the infinite possibility of space and time and a *finite* number of elements of experience.

XIII

148 We might also ask: What is it that goes on when, while we've as yet no idea how a certain proposition is to be proved, we still ask 'Can it be proved or not?' and proceed to look for a proof? If we 'try to prove it', what do we do? Is this a search which is essentially unsystematic, and therefore strictly speaking *not a search at all*, or can there be some plan involved? How we answer this question is a pointer as to whether the as yet unproved--or as yet unprovable--proposition is senseless or not. For, in a very important sense, every significant proposition must teach us through its sense how we are to convince ourselves whether it is true or false. 'Every proposition says what is the case if it is true.' And with a mathematical proposition this 'what is the case' must refer to the way in which it is to be proved. Whereas--and this is the point--you cannot have a logical plan of search for a *sense* you don't know. The sense would have to be, so to speak, revealed to us: revealed from without--since it can't be obtained from the propositional sign alone--in contrast with its truth, where the proposition itself tells us how to look for its truth and compare the truth with it.

This amounts to asking: Does a mathematical proposition tie something down to a Yes or No answer? (i.e. precisely a sense.)

My explanation mustn't wipe out the existence of mathematical problems. That is to say, it isn't as if it were only certain that a mathematical proposition made sense when it (or its opposite) had been proved. (This would mean that its opposite would never have a sense (Weyl).) On the other hand, it could be that certain apparent problems lose their character as problems--the question as to Yes or No.

149 Is it like this: I need a new insight at each step in a proof? This is connected with the question of the individuality of each

number. Something of the following sort: Supposing there to be a certain general rule (therefore one containing a variable), I must recognize each time afresh that this rule may be applied *here*. No act of foresight can absolve me from this act of *insight* [†1]. Since the form to which the rule is applied is in fact different at every step.

A proof of relevance would be a proof which, while yet not proving the proposition [would show the form of a method to be followed in order to test such a proposition] [†2]. And just that could make such a proof possible. It wouldn't get to the top of the ladder since *that* requires that you pass every rung; but only show that the ladder leads in this direction. That is, there's no substitute for stepping on every rung, and whatever is equivalent to doing so must in its turn possess the same multiplicity as doing so. (There are no surrogates in logic.) Neither is an arrow a surrogate for going through all the stages towards a particular goal. This is also connected with the impossibility of an hierarchy of proofs.

Wouldn't the idea of an hierarchy mean that merely posing a problem would have to be already preceded by a proof, i.e. a proof that the question makes sense? But then I would say that a proof of sense must be a radically different sort of proof from one of a proposition's truth, or else it would in its turn presuppose yet another and we'd get into an infinite regress.

Does the question of relevance make sense? If it does, it must always be possible to say whether the axioms are relevant to this proposition or not, and in that case this question must always be decidable, and so a question of the *first* type has already been decided. And if it can't be decided, it's completely senseless.

What, apart from Fermat's alleged proof, drives us to concern ourselves with the formula $x^n + y^n = z^n \dots (F)$, is the fact that we never happen upon cardinal numbers that satisfy the equation; but that doesn't give the *slightest* support (probability) to the general theorem and so doesn't give us any good reason for concerning ourselves with the formula. Rather, we may look on it simply as a notation for a particular general form and ask ourselves whether syntax is *in any way at all* concerned with this form.

I said: Where you can't look for an answer, you can't ask either, and that means: Where there's no logical method for finding a solution, the question doesn't make sense either.

Only where there's a method of solution is there a problem (of course that doesn't mean 'Only when the solution has been found is there a problem').

That is, where we can only expect the solution from some sort of revelation, there isn't even a problem. A revelation doesn't correspond to any question.

It would be like wanting to ask about experiences belonging to a sense organ we don't yet possess. Our being given a new sense, I would call revelation.

Neither can we *look for* a new sense (sense-perception).

150 We come back to the question: In what sense can we *assert* a mathematical proposition? That is: what *would* mean nothing would be to say that I can only assert it if it's correct.--No, to be able to make an assertion, I must do so with reference to its sense, not its truth. As I've already said, it seems clear to me that I can assert a general proposition as much or as little as the equation $3 \times 3 = 9$ or $3 \times 3 = 11$.

It's almost unbelievable, the way in which a problem gets completely barricaded in by the wrong expressions which generation

upon generation throw up for miles around it, so that it's virtually impossible to get at it.

What makes understanding difficult is the misconception of the *general* method of solution as only an--incidental--expedient for deriving numbers satisfying the equation. Whereas it is in itself a clarification of the essence (nature) of the equation. Again, it isn't an incidental device for discovering an extension, it's an end in itself.

What questions can be raised concerning a form, e.g. $fx = gx$?--Is $fx = gx$ or not (x as a general constant)? Do the rules yield a solution of this equation or not (x as unknown)? Do the rules prohibit the form $fx = gx$ or not (x construed as a stop-gap)?

None of these cases admits of being tested empirically, and so extensionally.

Not even the last two, since I see that e.g., ' $x^2 = 4$ ' is permitted no less from $7^2 = 4$ than from $2^2 = 4$, and that $x^2 = -4$ is prohibited isn't shown me by $2^2 \neq -4$ in any different way from that by which $8^2 \neq -4$ shows it me. That is, in the particular case, I again see here only the rule.

The question 'Do any numbers satisfy the equation?' makes no sense, no more than does 'It is satisfied by numbers', or, of course, than 'It is satisfied by all (no) numbers'.

The important point is that, even in the case where I am given that $3^2 + 4^2 = 5^2$, I ought *not* to say ' $(\exists x, y, z, n) \cdot x^n + y^n = z^n$ ', since taken extensionally that's meaningless, and taken intensionally this doesn't provide a proof of it. No, in this case I ought to express only the first equation.

It's clear that I may only write down the general proposition (using general constants), when it is analogous to the proposition $25 \times 25 = 625$, and that will be when I know the rules for calculating with a and b just as I know

those for 6, 2 and 5. This illustrates

Page Break 174

precisely what it means to call a and b constants here--i.e. constant forms [\dagger 1].

Page 174

Is it like this: I can't use the word 'yields' while I am unaware of any method of solution, since *yields* refers to a structure that I cannot designate unless I am aware of it. Because the structure must be *represented*.

Page 174

Every proposition is the signpost for a verification.

Page 174

If I construe the word 'yields' in an essentially intensional way, then the proposition 'The equation E yields the solution a ' means nothing until the word 'yields' stands for a definite method. For it is precisely this which I wish to refer to.

Page Break 175

Page 175

I have here nothing other than the old case that I cannot say two complexes stand in a relation without using a logical mapping of the relation.

Page 175

'The equation yields a ' means: If I transform the equation in accordance with certain rules, I get a , just as the equation $25 \times 25 = 620$ says that I get 620 if I apply the rules for multiplication to 25×25 . But these rules must already be given to me before the word 'yields' has a meaning and before the question whether the equation yields a has a sense.

Page 175

Thus Fermat's proposition makes no *sense* until I can *search* for a solution to the equation in cardinal numbers.

Page 175

And 'search' must always mean: search systematically. Meandering about in infinite space on the look-out for a gold ring is no kind of search.

Page 175

You can only *search* within a system: And so there is necessarily something you *can't* search for [\dagger 1].

Page 175

151 We may only put a question in mathematics (or make a conjecture), where the answer runs: 'I must work it out'.

Page 175

But can't I also say this is the case of $1/3 = 0.\dot{3}$, where the result isn't an extension, but the formation of the inductive relationship?

Page 175

But even so, we must also have a clear idea of this inductive relationship if we are to expect it.

Page 175

That is: even here we still can't conjecture or expect in a void.

Page 175

What 'mathematical questions' share with genuine questions is simply that they can be answered.

Page Break 176

Page 176

If the $\dot{3}$ in $1/3 = 0.\dot{3}$ refers to a definite method, then 0.110 as connected with F means nothing, since a method is lacking here [\dagger 1].

Page 176

A law I'm unaware of isn't a law.

Page 176

A mathematical question must be as exact as a mathematical proposition.

Page 176

The question 'How many solutions are there to this equation?' is the holding in readiness of the general method for solving it. And that, in general, is what a question is in mathematics: the holding in readiness of a general

method.

Page 176

I need hardly say that where the law of the excluded middle doesn't apply, no other law of logic applies either, because in that case we aren't dealing with propositions of mathematics. (Against Weyl and Brouwer.)

Page 176

Wouldn't all this lead to the paradox that there are no difficult problems in mathematics, since, if anything is difficult, it isn't a problem?

Page 176

But it isn't like that: The difficult mathematical problems are those for whose solution we don't yet possess a *written* system. The mathematician who is looking for a solution then has a system in some sort of psychic symbolism, in images, 'in his head', and endeavours to get it down on paper. Once that's done, the rest is easy. But if he has *no kind* of system, either in written or unwritten

Page Break 177

symbols, then he can't *search* for a solution either, but at best can only grope around.--Now, of course you may find something even by random groping. But in that case you haven't searched for it, and, from a logical point of view, the process was synthetic; whereas searching is a process of analysis.

Page 177

Whatever one can tackle is a problem [\dagger 1].

Page 177

Only where there can be a problem can something be asserted.

Page 177

If I know the rules of elementary trigonometry, I can check the proposition $\sin 2x = 2 \sin x \cdot \cos x$, but not the proposition $\sin x = x - \frac{x^3}{3!} + \dots$. But that means that the sine function of elementary trigonometry and that of higher trigonometry are *different* concepts. If we give them the same name, we admittedly do so with good reason, since the second concept includes within itself the multiplicity of the first; but as far as the system of elementary trigonometry is concerned, the second proposition makes *no sense*, and it is of course senseless in this context to ask whether $\sin x = x$ --etc.

Page 177

152 Is it a genuine question if we ask whether it's possible to trisect an angle? And of what sort is the proposition and its proof that it's impossible with ruler and compasses alone?

Page 177

We might say, since it's impossible, people could never even have tried to look for a construction.

Page 177

Until I can *see* the larger system encompassing them both, I can't try to solve the higher problem.

Page 177

I can't ask whether an angle can be trisected with ruler and compasses, until I can see the system 'Ruler and Compasses' as embedded in a larger one, where the problem is soluble; or better, where the problem is a problem, where this question has a sense.

Page Break 178

Page 178

This is also shown by the fact that you *must* step outside the Euclidean system for a proof of the impossibility.

Page 178

A system is, so to speak, a world.

Page 178

Therefore we can't search for a system: What we *can* search for is the expression for a system that is given me in unwritten symbols.

Page 178

A schoolboy, equipped with the armoury of elementary trigonometry and asked to test the equation $\sin x = x$ --etc., simply wouldn't find what he needs to tackle the problem. If the teacher nevertheless expects a solution from him, he's assuming that the multiplicity of the syntax which such a solution presupposes is in some way or other present in a different form in the schoolboy's head--present in such a way that the schoolboy sees the symbolism of elementary trigonometry as a part of this unwritten symbolism and now translates the rest from an unwritten into a

written form.

Page 178

The system of rules determining a calculus thereby determines the 'meaning' of its signs too. Put more strictly: The form and the rules of syntax are equivalent. So if I change the rules--seemingly supplement them, say--then I change the form, the meaning.

Page 178

I cannot draw the limits of my world, but I can draw limits within my world. I cannot ask whether the proposition p belongs to the system S , but I can ask whether it belongs to the part s of S . So that I can locate the problem of the trisection of an angle within the larger system, but can't ask, within the Euclidean system, whether it's soluble. In what *language* should I ask this? in the Euclidean? But neither can I ask in Euclidean language about the possibility of bisecting an angle within the Euclidean system. For

Page Break 179

in this language that would boil down to a question about absolute possibility, and such a question is always nonsense.

Page 179

But there's nothing to be found here which we could call a hierarchy of types.

Page 179

In mathematics, we cannot talk of systems in general, but only *within* systems. They are just what we can't talk about. And so, too, what we can't search for.

Page 179

The schoolboy that lacked the equipment for answering the second question, couldn't merely not answer it, he couldn't even understand it. (It would be like the task the prince set the smith in the folk tale: Fetch me a 'Fiddle-de-dee'.)

Page 179

Every legitimate mathematical proposition must put a ladder up against the problem it poses, in the way that $12 \times 13 = 137$ does--which I can then climb if I choose.

Page 179

This holds for propositions of any degree of generality. (N.B. there is no ladder with 'infinitely many' rungs.)

Page 179

Now suppose I have two systems: I can't enquire after one system encompassing them both, since not only am I unable now to search for this system, but even in the event of one turning up that encompasses two systems analogous to the original ones, I see that I could never have looked for it.

Page 179

153 Proofs proving the same thing may be translated into one another, and to that extent are the same proof. The only proofs for which this doesn't hold are like: 'From two things, I infer that he's at home: first his jacket's in the hall, and also I can hear him whistling'. Here we have two independent ways of knowing. This proof requires grounds that come from outside, whereas a mathematical proof is an analysis of the mathematical proposition.

Page Break 180

Page 180

What is a proof of provability? It's different from the proof of proposition.

Page 180

And is a proof of provability perhaps the proof that a proposition makes sense? But then, such a proof would have to rest on *entirely different* principles from those on which the proof of the proposition rests. There cannot be an hierarchy of proofs!

Page 180

On the other hand there can't in any fundamental sense be such a thing as metamathematics. Everything must be of one type (or, what comes to the same thing, not of a type).

Page 180

Now, is it possible to show that the axioms are relevant to a proposition (i.e. prove it or its opposite), without actually bringing them to bear directly on it? That is, do we only know whether they are relevant when we've got there, or is it possible to know this at an earlier stage? And is the possibility of checking $36 \times 47 = 128$ a proof of this? It obviously makes sense to say 'I know how you check that', even before you've done so.

Page 180

Thus, it isn't enough to say that p is provable, what we must say is: provable according to a particular system.

Page 180

Further, the proposition doesn't assert that p is provable in the system S , but in *its own* system, the system of p . That p belongs to the system S cannot be asserted, but must show itself.

Page 180

You can't say p belongs to the system S ; you can't ask which system p belongs to; you can't search for the system of p . Understanding p means understanding its system. If p appears to go over from one system into another, then p has, in reality, changed its sense.

Page 180

Ramsey believed that what I call recognizing the system was nothing more than the application--perhaps unconscious--of a general mathematical proposition. So that if I know that the question of the correctness of $\sin 3a = 5 \cos a$ is decidable, I

Page Break 181

merely deduce that from the laws for $\sin(a + b)$ etc. But this isn't right: on the contrary, I derive it from the fact that there is such a law, not from how it runs.

Page 181

154 I could gather together numerical equations and equations using variables as follows: Transforming the left-hand side in accordance with certain rules either does or does not yield the right-hand side.

Page 181

But for this to be so, the two sides of the equation (N.B. of the *general* equation) must, so to speak, be *commensurable*.

Page 181

The classifications made by philosophers and psychologists are like those that someone would give who tried to classify clouds by their shapes.

Page 181

What a mathematical proposition says is always what its proof proves. That is to say, it never says more than its proof proves.

Page 181

If I had a method for distinguishing equations with a solution from those without, then in terms of this method the expression ' $(\exists x) \cdot x^2 = 2x$ ' would make sense.

Page 181

I can ask 'What is the solution of the equation $x^2 = 2x$?', but not 'Has it a solution?' For what would it look like for it to have none? A proposition has a sense only if I know what is the case if it is false.--But suppose the alternative case were something like the equation ' $(\exists x) \cdot x^2 - 2x - x(x - 2) = 0$ '? In that case at any rate, the proposition $(\exists x) \cdot x^2 = 2x$ would make sense and it would be proved by the fact that the rules don't allow us to reduce the two sides to one another. In reply to the question 'Is there a solution of the equation $x^n + ax^{n-1} + \dots + z = 0$?', we may always ask 'As opposed to what?'

Page 181

$25 \times 25 = 625$. What constitutes the system which shows me the commensurability in this case?

Page 181

Surely that multiplication of two numbers written in this form always gives me a number of the same form, and a rule for two

Page Break 182

numerical signs of this form decides whether they designate the same or different numbers.

Page 182

We could also characterize this idea as follows: 'It's impossible for us to discover rules of a new type that hold for a form with which we are familiar. If they are rules which are new to us, then it isn't the old form. The edifice of rules must be *complete*, if we are to work with a concept at all--*we cannot make any discoveries in syntax*--For, only the group of rules *defines* the sense of our signs, and any alteration (e.g. supplementation) of the rules means an alteration of the sense.

Page 182

Just as we can't alter the marks of a concept without altering the concept itself. (Frege)

Page 182

A system is a formal series, and it is precisely in the rules of the series that the iterations yielding its successive members are described.

Page 182

The negation of 'It is necessary that p holds for all numbers' is of course 'It is not necessary that...', not 'It is

necessary that not...'. But now we think: if it isn't *necessary* that p holds for all numbers, it's surely still possible. But this is where the fallacy lies, since we don't see that we've slipped into the extensional way of looking at things: the proposition 'It's possible--though not necessary--that p should hold for all numbers' is nonsense. For in mathematics '*necessary*' and '*all*' go together. (Unless we replace these idioms throughout by ones which are less misleading.)

Page 182

155 What kind of discovery was it, e.g., that Sheffer made when he showed that we can reduce all the truth-functions to $p|q$? Or the discovery of the method for extracting the cube root? What's going on when we have to resort to a dodge in Mathematics? (As when solving an equation or integrating.) Here it's like unravelling a knot. I can try out one way or another at random and

Page Break 183

the knot may get even more tangled or come undone. (Whatever happens, each operation is a permissible one and leads *somewhere*.)

Page 183

I want to say that finding a system for solving problems which previously could only be solved one by one by separate methods isn't merely discovering a more convenient vehicle, but is something completely new which previously we didn't have at all. The uniform method precisely isn't just the method for constructing an object, which is the same no matter how it was constructed. The method isn't a vehicle taking us to a place which is our real goal no matter how we arrive at it.

Page 183

That is to say: In my opinion, no *way* can be found in mathematics which isn't also a goal. You can't say: I already had all these results, now all I've done is find an even better way that leads to all of them. No: this way is a new place that we previously lacked. The new way amounts to a new system.

Page 183

Wouldn't this imply that we can't learn anything new about an object in mathematics, since, if we do, it is a new object?

Page 183

This boils down to saying: If I hear a proposition of, say, number theory, but don't know how to prove it, then I don't understand the proposition either. This sounds extremely paradoxical. It means, that is to say, that I don't understand the proposition that there are infinitely many primes, unless I know its so-called proof: when I learn the proof, I learn something *completely new*, and not just the way leading to a goal with which I'm already familiar.

Page 183

But in that case it's unintelligible that I should admit, when I've got the proof, that it's a proof of precisely *this* proposition, or of the induction meant by this proposition.

Page Break 184

Page 184

I want to say, it isn't the prose which is the mathematical proposition, it's the exact expression [\dagger 1].

Page 184

There can't be two independent proofs of one mathematical proposition.

Page 184

156 Unravelling knots in mathematics: Can someone *try* to unravel a knot which is subsequently shown to be impossible to untie? People succeeded in resolving the cubic equation, they *could not* have succeeded in trisecting an angle with ruler and compasses; people had been grappling with both these problems long before they knew how to solve the one and that the other was insoluble.

Page 184

Let's consider something that appears to be a knot, but is in reality made up of many loops of thread and perhaps also a few threads with loose ends. I now set someone the task of unravelling the knot. If he can see the arrangement of the threads clearly, he'll

Page Break 185

say 'That's not a knot and so there's no such thing as unravelling it'. If he can only see a jumble of threads, then he may try to untie it, pulling various ends at random, or actually making a few transformations that are the result of having a clear picture of some parts of the knot, even though he hasn't seen its structure as a whole.

Page 185

I would say here we may only speak of a genuine attempt at a solution *to the extent* that the structure of the

knot is seen clearly. To the extent that it isn't, everything is groping in the dark, since it's certainly possible that something which looks like a knot to me isn't one at all; (the best proof that I in fact had no method for searching for a solution). We can't compare what goes on here with what happens when I make a methodical search of a room for something, and so discover that it isn't there. For in this case I am searching for a possible state of affairs, not an impossible one.

Page 185

But now I want to say that the analogy with a knot breaks down, since I can have a knot and get to know it better and better, but in the case of mathematics I want to say it isn't possible for me to learn more and more about something which is already given me in my signs, it's always a matter of learning and designating something *new*.

Page 185

I don't see how the signs, which we ourselves have made for expressing a certain thing, are supposed to create problems for us.

Page 185

It's more like a situation in which we are gradually shown more and more of a knot or tangle, and we make ourselves a series of pictures of as much of it as we can see. We have no idea what the part of the knot not yet revealed to us is like and can't in any way make conjectures about this (say, by examining the pictures of the part we know already).

Page Break 186

Page 186

157 What did people discover when they found there was an infinity of primes? What did people discover when they realized there was an infinity of cardinals?--Isn't it exactly similar to the recognition--if that is what it is--that Euclidean Space is infinite, long after we have been forming propositions about the objects in this space.

Page 186

What is meant by an investigation of space?--For every mathematical investigation is a sort of investigation of space [†1]. It's clear that we can investigate the *things* in space--but space itself! (Geometry and Grammar always correspond with one another.)

Page 186

Let's remember that in mathematics, the signs themselves *do* mathematics, they don't describe it. The mathematical signs *are* like the beads of an abacus. And the beads are in space, and an investigation of the abacus is an investigation of space.

Page 186

What wasn't foreseen, wasn't foreseeable; for people lacked the system within which it could have been foreseen. (And would have been.)

Page 186

You can't write mathematics [†2], you can only do it. (And for that very reason, you can't 'fiddle' the signs in mathematics.)

Page 186

Suppose I wanted to construct a regular pentagon but didn't know how, and were now to make experiments at random, finally coming upon the right construction by accident: Haven't we here an actual case of a knot which is untied by trial and error? No, since if I don't understand this construction, as far as I'm concerned it doesn't even begin to be the construction of a pentagon.

Page 186

Of course I can write down the solution of a quadratic equation by accident, but I can't understand it by accident. The way I have

Page Break 187

arrived at it vanishes in what I understand. I then understand what I understand. That is, the accident can only refer to something purely external, as when I say 'I found that out after drinking strong coffee.' The coffee has no place in what I discovered.

Page 187

158 The discovery of the connection between two systems wasn't in the *same* space as those two systems, and if it had been in the same space, it wouldn't have been a discovery (but just a piece of homework).

Page 187

Where a connection is now known to exist which was previously unknown, there wasn't a gap before, something incomplete which has now been filled in!--(At the time, we weren't in a position to say 'I know this much

about the matter, from here on it's unknown to me.')

Page 187

That is why I have said there are no gaps in mathematics. This contradicts the usual view.

Page 187

In mathematics there is no 'not yet' and no 'until further notice' (except in the trivial sense that we haven't yet multiplied two 1,000-digit numbers together).

Page 187

An induction has a great deal in common with the multiplicity of a class (a finite class, of course). But all the same it isn't one, and now it is called an infinite class.--

Page 187

If, e.g., I say, 'If I know one whorl, I know the whole spiral', that strictly means: if I know the law of a spiral, that's in many respects analogous with the case in which I know a totality of whorls.--But naturally a 'finite' totality, since that's the only kind there is.--We can't now say: I agree it's in many ways analogous with a finite totality, but on the other hand it's completely analogous with an infinite one; that an induction isn't *completely* analogous with a totality is simply all we can say.

Page Break 188

Page 188

Mathematics cannot be incomplete; any more than a *sense* can be incomplete. Whatever I can understand, I must completely understand. This ties up with the fact that my language is in order just as it stands, and that logical analysis does not have to add anything to the sense present in my propositions in order to arrive at complete clarity. So that even the most unclear seeming proposition retains its previous content intact after the analysis and all that happens is that its grammar is made clear.

Page 188

159 But doesn't it still have to count as a question, whether there is a finite number of primes or not?--Once you have acquired this concept at all. For it certainly seems that the moment I'm introduced to the concept of a prime number, I can ask 'How many are there?' Just as I can ask 'How many are there?' straight off when I am given the concept 'man in this room'.

Page 188

If I am misled by this analogy, it can only be because the concept 'prime number' is given me in a completely different way from a genuine concept. For, what is the strict expression of the proposition '7 is a prime number'? Obviously it is only that dividing 7 by a smaller number always leaves a remainder. There cannot be a different expression for that, since we can't describe mathematics, we can only do it. (And that of itself abolishes every 'set theory'.)

Page 188

Therefore once I can write down the general form of prime number, i.e. an expression in which anything analogous to 'the number of prime numbers' is contained at all, then there is no longer a question of 'how many' primes there are, and until I can do this, I also can't put the question. For, I can't ask 'Does the series of primes *eventually* come to an end?' nor, 'Does another prime *ever* come after 7?'

Page 188

For since it was possible for us to have the phrase 'prime number' in ordinary language, even before there was the strict expression which so to speak admitted of having a number assigned

Page Break 189

to it, it was also possible for people to have wrongly formed the question how many primes there were. This is what creates the impression that previously there was a problem which is now solved. Verbal language seemed to permit this question both before and after, and so created the illusion that there had been a genuine problem which was succeeded by a genuine solution. Whereas in exact language people originally had nothing of which they could ask how many, and later an expression from which one could immediately read off its multiplicity.

Page 189

Thus I want to say: only in our verbal language (which in this case leads to a misunderstanding of logical form) are there in mathematics 'as yet unsolved problems' or the problem of the finite 'solubility of every mathematical problem'.

Page 189

160 It seems to me that the idea of the consistency of the axioms of mathematics, by which mathematicians are so haunted these days, rests on a misunderstanding.

Page 189

This is tied up with the fact that the axioms of mathematics are not seen for what they are, namely, propositions of syntax.

Page 189

There is no question as to provability, and in *that* sense no proof of provability either. The so-called proof of provability is an induction, to recognize which is to recognize a new system.

Page 189

A consistency proof can't be essential for the application of the axioms.

Page 189

A postulate is only the postulation of a form of expression. The 'axioms' are postulates of the form of expression.

Page 189

161 The comparison between a mathematical expedition and a polar expedition. There is a point in drawing this comparison, and it is a very useful one.

Page Break 190

Page 190

How strange it would be if a geographical expedition were uncertain whether it had a goal, and so whether it had any route whatsoever. We can't imagine such a thing, it's nonsense. But this is precisely what it is like in a mathematical expedition. And so perhaps it's a good idea to drop the comparison altogether.

Page 190

It would be an expedition, which was uncertain of *the space* it was in!

Page 190

How can there be conjectures in mathematics? Or better: what sort of thing is it that looks like a conjecture in mathematics? Such as making a conjecture about the distribution of primes.

Page 190

I might, e.g., imagine that someone is writing the primes in series in front of me without my knowing they are the primes--I might for instance believe he is writing down numbers just as they occur to him--and I now try to detect a law in them. I might now actually form an hypothesis about this number sequence, just as I could about any other sequence yielded by an experiment in physics.

Page 190

Now in what sense have I, by so doing, made an hypothesis about the distribution of primes?

Page 190

You might say that an hypothesis in mathematics has the value that it trains your thoughts on a particular object--I mean a particular region--and we might say 'we shall surely discover something interesting about these things'.

Page 190

The trouble is that our language uses each of the words 'question', 'problem', 'investigation', 'discovery' to refer to such basically different things. It's the same with 'inference', 'proposition', 'proof'.

Page 190

The question again arises, what kind of verification do I count as valid for my hypothesis? Or, can I--*faute de mieux*--allow an empirical one to hold for the time being, until I have a 'strict

Page Break 191

proof'? No. Until there is such a proof, there's no connection at all between hypothesis and the 'concept' of a prime number.

Page 191

The concept of a prime number is the general law by means of which I test whether a number is a prime number or not.

Page 191

Only the so-called proof establishes any connection between my hypothesis and the primes *as such*. And that is shown by the fact that--as I've said--until then, the hypothesis can be construed as one belonging purely to physics.--On the other hand, when we have supplied a proof, it doesn't prove what was conjectured at all, since I can't conjecture to infinity. I can only conjecture what can be confirmed, but experience can only confirm a finite number of conjectures and you can't conjecture the proof until you've got it--and not then either.

Page 191

The concept 'prime number' is the general form of investigation of a number for the relevant property; the concept 'composite' the general form of investigation for divisibility etc.

162 What kind of discovery did Sheffer make when he found that $p \vee q$ and $\sim p$ can be expressed by means of $p|q$? People had no method for looking for $p|q$, and if someone were to find one today, it wouldn't make any difference.

What was it we didn't know before the discovery? It wasn't anything that we didn't know, it was something with which we weren't acquainted.

You can see this very clearly if you imagine someone objecting that $p|p$ isn't at all the same as is said by $\sim p$. The reply, of course, is that it's only a question of the system $p|q$ etc. having the necessary multiplicity. Thus Sheffer found a symbolic system with the necessary multiplicity.

Does it count as looking for something, if I am unaware of Sheffer's system and say I would like to construct a system with only *one* logical constant? No!

Systems are certainly not all in *one* space, so that I could say:

there are systems with 3 and with 2 logical constants, and now I am trying to reduce the number of constants *in the same way*. There is no '*same way*' here.

We might also put it like this: the completely analysed mathematical proposition is its own proof.

Or like this: a mathematical proposition is only the immediately visible surface of a whole body of proof and this surface is the boundary facing us.

A mathematical proposition--unlike a genuine proposition--is *essentially* the last link in a demonstration that renders it visibly right or wrong.

We can imagine a notation in which every proposition is represented as the result of performing certain operations--transitions--on particular 'axioms' treated as bases. (Roughly in the same way as chemical compounds are represented by means of such names as 'trimethylamide' etc.)

With a few modifications, such a notation could be constructed out of the instructions with which Russell and Whitehead preface the propositions of *Principia Mathematica*.

A mathematical proposition is related to its proof as the outer surface of a body is to the body itself. We might talk of the body of proof belonging to the proposition.

Only on the assumption that there's a body behind the surface, has the proposition any significance for us.

We also say: a mathematical proposition is the last link in a chain of proof.

XIV

163 ' $a + (b + c) = (a + b) + c$ '... $A(c)$ can be construed as a basic rule of a system. As such, it can only be laid down, but not *asserted*, or denied (hence no law of the excluded middle). But I can apparently also regard the proposition as the result of a proof. Is this proof the answer to a question and, if so, which? Has it shown an assertion to be true and so its negation to be false?

But now it looks as though I cannot prove the proposition at all in the sense in which it is a basic rule of a system. Rather, I prove something about it.

This is tied up with the question whether you can deny $2 = 2$, as you can $2 \times 35 = 70$, and why you cannot deny a definition.

In school, children admittedly learn that $2 \times 2 = 4$, but not that $2 = 2$.

Page 193

If we want to see what has been proved, we ought to look at nothing but the proof.

Page 193

We ought not to confuse the infinite possibility of its application with what is actually proved. The infinite possibility of application is *not* proved!

Page 193

The most striking thing about a recursive proof is that what it alleges to prove is not what comes out of it.

Page 193

The proof shows that the form ' $a + (b + (c + 1)) = (a + b) + (c + 1)$ '... ' $A(c + 1)$ ' follows from the form 1) ' $A(c)$ '

in accordance with the rule 2) ' $a + (b + 1) = (a + b) + 1$ '... ' $A(1)$ '. Or, what comes to the same thing, by means of the rules 1) and 2) the form ' $a + (b + (c + 1))$ ' can be transformed into ' $(a + b) + (c + 1)$ '. This is the sum total of what is actually in the proof. Everything else, and the whole of the usual interpretation, lies in the possibility of its application. And the usual mistake, in

Def

Page Break 194

confusing the extension of its application with what it genuinely contains.

Page 194

Of course, a definition is not something that I can deny. So it does not have a sense, either. It is a rule by which I can proceed (or have to proceed).

Page 194

I cannot negate the basic rules of a system.

Page 194

In Skolem's proof the ' c ' doesn't have any meaning *during* the proof, it stands for 1 or for what may perhaps come out of the proof, and *after* the proof we are justified in regarding it as some number or other. But it must surely have already meant something in the proof. If 1, why then don't we write '1' instead of ' c '? And if something else, what? [†1]

Page Break 195

Page 195

If we now suppose that I wish to apply the theorem to 5, 6, 7, then the proof tells me I am certainly entitled to do so. That is to say, if I write these numbers in the form $((1 + 1) + 1)$ etc., then I can recognize that the proposition is a member of the series of propositions that the final proposition of Skolem's chain presents me with. Once more, this recognition is not provable, but intuitive.

Page Break 196

Page 196

'Every symbol is what it is and not another symbol.'

Page 196

Can there be no proof which merely shows that every multiplication in the decimal system in accordance with the rules must yield a number of the decimal system? (So that recognizing the same system would thus after all depend on recognizing the truth of a mathematical proposition.)

Page 196

It would have to be analogous to a proof that by addition of forms $((1 + 1) + 1)$ etc. numbers of this form would always result. Now, can that be proved? The proof obviously lies in the rule for addition of such expressions, i.e. in the definition and in nothing else.

Page 196

Indeed, we might also reply to the question for which this proof is to provide the answer: Well, what *else* do you expect the addition to yield?

Page 196

164 A recursive proof is only a general guide to an arbitrary special proof. A signpost that shows every proposition of a particular form a particular way home. It says to the proposition $2 + (3 + 4) = (2 + 3) + 4$: 'Go in *this* direction (run through this spiral), and you will arrive home.'

Page 196

To what extent, now, can we call such a guide to proofs the proof of a general proposition? (Isn't that like wanting to ask: 'To what extent can we call a signpost a route?')

Yet it surely does justify the application of $A(c)$ to numbers. And so mustn't there, after all, be a legitimate transition from the proof schema to this expression?

I know a proof with endless possibility, which, e.g., begins with 'A(1)' and continues through 'A(2)' etc. etc. The recursive proof is the general form of continuing along this series. But it itself must still prove something since it in fact spares me the trouble of proving each proposition of the form 'A(7)'. But how can it

prove this proposition? It obviously points along the series of proofs

$$\begin{array}{c}
 \swarrow \quad \searrow \\
 a + (b + (\xi + d)) = (a + (b + \xi)) + d = ((a + b) + \xi) + d = (a + b) + (\xi + d) \\
 \swarrow \quad \searrow \\
 a + (b + ((\xi + d))) = (a + (b + (\xi + d))) + d = ((a + b) + (\xi + d)) + d = (a + b) + ((\xi + d) + d) \\
 \swarrow \quad \searrow
 \end{array}$$

That is a stretch of the spiral taken out of the middle.

ξ is a stop-gap for what only emerges in the course of the development.

If I look at this series, it may strike me that it is akin to the definition $A(1)$; that if I substitute '1' for 'c' and '1' for 'd', the two systems are the same.

In the proof, at any rate, what is to be proved is not the end of the *chain of equations*.

The proof shows the spiral form of the law.

But not in such a way that it comes out as the conclusion of the chain of inferences.

It is also very easy to imagine a popular introduction of the proof using 1, perhaps followed by dots to indicate what we are to look out for. It wouldn't in essence be any less strict. (For the peculiarity of the proof stands out even more clearly in this case.)

Let's imagine it like this. How does it then justify the proposition $A(c)$?

If one regards the proof as being of the same sort as the derivation of $(x + y)^2 = x^2 + 2xy + y^2$, then it proves the proposition 'A(c + 1)' (on the hypothesis 'A(c)', and so of the proposition I really want to prove). And justifies--on this assumption special cases such as $3 + (5 + (4 + 1)) = (3 + 5) + (4 + 1)$. It also has a generality, but not the one we desire. This generality does not lie

in the letters, but just as much in the particular numbers and consists in the fact that we can repeat the proof.

But how can I use the sign ' $f(a)$ ' to indicate what I see in the passage from $f(1)$ to $f(2)$? (i.e. the possibility of repetition.)

Neither can I prove that $a + (b + 1) = (a + b) + 1$
 is a special case of $a + (b + c) = (a + b) + c$:
 I must see it.

(No rule can help me here either, since I would still have to know what would be a special case of this general rule.)

This is the unbridgeable gulf between rule and application, or law and special case.

$A(c) [\dagger 1]$ is a definition, a rule for algebraic calculation. It is chosen in such a way that this calculation agrees with arithmetical calculation. It permits the same transition in algebraic calculation that holds for cardinal numbers, as may be seen in the recursive proof. Thus $A(c)$ is not the result of a proof, it so to speak runs parallel with it.

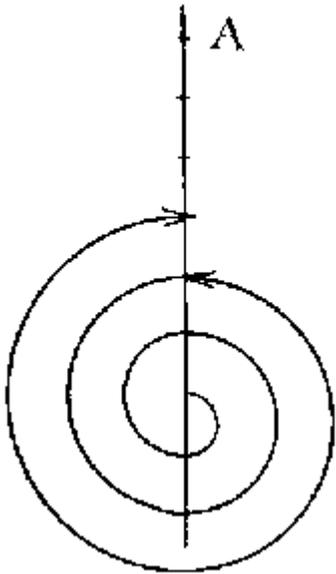

What we gather from the proof, we cannot represent in a proposition at all and of course for the same reason we can't deny it either.

But what about a definition like $A(1) [\dagger 2]$? This is not meant as a rule for algebraic calculation, but as a device for explaining arithmetical expressions. It represents an *operation*, which I can apply to an arbitrary pair of numbers.

165 The correct expression for the associative law is not a proposition, but precisely its 'proof', which admittedly doesn't state the law, but shows it. And at this point it becomes clear that we cannot

deny the law, since it doesn't figure in the form of a proposition at all. We could of course deny the individual equations of the law, but would not thereby deny the law: that *eludes* affirmation and denial.

To know that you can prove something is to have proved it.

$7 + (8 + 9) = (7 + 8) + 9$. How do I know that this is so, without having to give a particular proof of it? And do I know *just as well* as if I had given a complete derivation of it? Yes!--Then that means it really is proved. What's more, in that case it cannot have a still *better* proof; say, by my carrying out the derivation as far as this proposition itself. So it must be possible for me to say after running through one turn of the spiral 'Stop! I don't need any more, I can already see how it goes on', and then every higher step must be purely superfluous and doesn't make the matter clearer. If I draw all the whorls of the spiral as far as my point, I cannot see that the spiral leads to it any better than if I draw only *one*. It is only that each shows the same thing in a different form. I can so to speak blindly follow the spiral that has been completely drawn in and arrive at my point, whereas the *one* whorl which has been drawn has to be interpreted in a particular way for me to perceive that, if continued, it leads to the point A.

That is to say: from the proof for $6 + (7 + 8) = (6 + 7) + 8$ which has been completely worked out, I can extract the same as from the one which only describes one 'whorl', but in a different way. And

at any rate the *one* whorl *in conjunction with the numerical forms* of the given equation is a complete proof of this equation. It's as though I were to say: 'You want to get to the point A? Well, you can get *there* along *this* spiral.'

When we teach someone how to take his first step, we thereby enable him to go any distance.

Page 200

166 As the immediate datum is to a proposition which it verifies, so is the arithmetical relation we see in the structure to the equation which it verifies.

Page 200

It is the real thing, not an expression for something else for which another expression could also be substituted. That is, it is not a symptom of something else, but the thing itself.

Page 200

For that is how it is usually construed (i.e. in the wrong way). One says an induction is a sign that such and such holds for all numbers. But the induction isn't a sign for anything but itself. If there were yet something besides the induction, for which *it* was a sign, this something would have to have its specific expression which would be nothing but the complete expression for this something.

Page 200

And this conception is then developed into the idea that the algebraic equation tells us what we see in the arithmetical induction. For that, it would have to have the same multiplicity as what it describes.

Page 200

How a proposition is verified is what it says. Compare the generality of genuine propositions with generality in arithmetic. It is differently verified and so is of a different kind.

Page 200

The verification is not *one* token of the truth, it is *the* sense of the proposition. (Einstein: How a magnitude is measured is what it is.)

Page 200

Indeed Russell has really already shown by his theory of descriptions, that you can't get a knowledge of things by sneaking up on

Page Break 201

them from behind and it can only *look* as if we knew more about things than they have shown us openly and honestly. But he has obscured everything again by using the phrase 'indirect knowledge'.

Page 201

167 An algebraic schema derives its sense from the way in which it is applied. So this must always be behind it. But then so must the inductive proof, since that justifies the application.

Page 201

An algebraic proposition is just as much an equation as $2 \times 2 = 4$, it is only applied differently. Its relation to arithmetic is different. It deals with the substitutability of other parts of speech.

Page 201

That is to say, an algebraic equation as an equation between real numbers is, *to be sure*, an arithmetical equation, since something arithmetical lies behind it. Only it lies behind the *algebraic* equation in a different way from the way it lies behind $1 + 1 = 2$.

Page 201

An induction doesn't prove the algebraic proposition, since only an equation can prove an equation. But it justifies the setting up of algebraic equations from the standpoint of their application to arithmetic.

Page 201

That is, it is only through the induction that they gain their sense, not their truth.

Page 201

For this reason, what can no longer be reduced to other equations, and can only be justified by induction, is a *stipulation*.

Page 201

Which is connected with the fact that in the application of this algebraic proposition I cannot appeal to it, but once again only to the induction.

Page 201

Hence these last equations can't be denied--i.e. there is no arithmetical content corresponding to their negation.

Page 201

Through them alone the algebraic system becomes applicable to numbers.

Page 201

And so in a particular sense they are certainly the expression of

Page Break 202

something arithmetical, but as it were the expression of an arithmetical *existence*.

Page 202

They alone make algebra into clothing for arithmetic--and are therefore arbitrary to the extent that no one compels us to use algebra in this way. They fit algebra on to arithmetic.

Page 202

And while it is wearing these clothes, it can move about in them.

Page 202

They are not the expression of something computable and to that extent are stipulations.

Page 202

Can someone who sees these stipulations learn something from them, in arithmetic? And, if so, what?--Can I learn an arithmetical state of affairs, and, if so, which?

Page 202

A stipulation is more like a name than like a proposition.

Page 202

You can only prove those propositions whose truth you can enquire into. 'Is it so or not?' 'I will prove to you it *is so*.'

Page 202

An induction is related to an algebraic proposition not as a proof is to what is proved, but as what is designated to a sign.

Page 202

The system of algebraic propositions corresponds to a *system* of inductions.

Page 202

168 A proof by induction, if it were a proof, would be a proof of generality, not a proof of a certain property of all numbers.

Page 202

We can only ask from a standpoint from which a question is possible. From which a doubt is possible.

Page 202

If one wanted to ask about $A(c)$, it wouldn't strictly speaking be the induction that answered us, but the humiliating feeling that we

Page Break 203

could only arrive at the thought of this equation by way of the induction.

Page 203

If we ask 'Does $a + (b + c) = (a + b) + c$?', what could we be after? Taken purely algebraically, the question means nothing, since the answer would be: 'Just as you like, as you decide.' Neither can the question mean 'Does this hold for all numbers?', it can only ask what the induction says: it, however, says nothing at all to us.

Page 203

We cannot ask about that which alone makes questions possible at all.

Page 203

Not about what first gives the system a foundation.

Page 203

That some such thing must be present is clear.

Page 203

And it is also clear that in algebra this first thing must present itself as a rule of calculation, which we can then use to test the other propositions.

Page 203

An algebraic proposition always gains only arithmetical significance if you replace the letters in it by numerals, and then always only *particular* arithmetical significance.

Page 203

Its generality doesn't lie in itself, but in the possibility of its correct application. And for that it has to keep on having recourse to the induction.

Page 203

That is, it does not assert its generality, it does not express it; the generality is, rather, shown in the formal relation to the substitution, which proves to be a term of the inductive series.

Page 203

$(\exists 24x) \bullet \phi x \bullet (\exists 18x) \bullet \psi x \bullet \text{Ind}: \supset: (\exists 24 + 18x) \bullet \phi x \vee \psi x$. How do I know that this is so, unless I have

introduced the concept of addition for the context of this application? I can only arrive at this proposition by induction. That is to say, corresponding to the general proposition--or rather, the tautology-- $(\exists nx) \cdot \phi x \cdot (\exists mx) \cdot \psi x \cdot \text{Ind}: \supset (\exists n + mx) \cdot \psi x \vee \psi x$, there is an induction, and this induction is the proof of the above proposition $(\exists 24x) \cdot \text{etc.}$, even before we have actually worked out $24 + 18$ and have tested whether it is a tautology.

Page Break 204

Page 204

To *believe* Goldbach's Conjecture, means to believe you have a proof of it, since I can't, as it were, believe it *in extenso*, because that doesn't mean anything, and you cannot imagine an induction corresponding to it until you have one.

Page 204

If the proof that every equation has a root is a recursive proof, then that means the Fundamental Theorem of Algebra isn't a genuine mathematical *proposition* [†1].

Page 204

169 If I want to know what ' $1/3 = 0.\dot{3}$ ' means, it's a relevant question to ask 'How can I know that?' For the proof comes as a reply to this 'how?', and more than is shown by this proof I certainly do not know.

Page 204

It is clear that every multiplication in the decimal system has a solution and therefore that one can prove any arithmetical equation of the form $a \times b = c$ or prove its opposite. What would a proof of this provability look like? It is obviously nothing further than a clarification of the symbolism and an exhibition of an induction from which it can be seen what sort of propositions the ladder leads to.

Page 204

I cannot deny the *generality* of a general arithmetical proposition.

Page 204

Isn't it only this generality that I cannot reflect in the algebraic proposition?

Page 204

An equation can only be proved by reducing it to equations.

Page 204

The last equations in this process are definitions.

Page 204

If an equation can't be reduced to other equations, then it is a definition.

Page 204

An induction cannot justify an equation.

Page 204

Therefore, e.g. the introduction of the notation $\dot{3}$ cannot refer to the induction whose sign it appears to be. The relation must be similar to that of 'A(c)' to its proof by induction.

Page Break 205

Page 205

Or better, it certainly refers to the bare facts of the induction, but not to the generality, which is its true sense.

Page Break 206

XV

Page 206

170 The theory of aggregates attempts to grasp the infinite at a more general level than a theory of rules. It says that you can't grasp the actual infinite by means of arithmetical symbolism at all and that therefore it can only be described and not represented. The description would encompass it in something like the way in which you carry a number of things that you can't hold in your hands by packing them in a box. They are then invisible but we still know we are carrying them (so to speak, indirectly). The theory of aggregates buys a pig in a poke. Let the infinite accommodate itself in this box as best it can.

Page 206

With this there goes too the idea that we can use language to describe logical forms. In a description of this sort the structures and e.g. correlations etc., are presented in a package, and so it does indeed look as if one could talk about a structure without reproducing it in the proposition itself. Concepts which are packed up like this and so whose structures are not recognisable may, to be sure, be used, but they always derive their meaning from

definitions which package the concepts in this way; and if we trace our way back through these definitions the concepts are then unpacked again and so are present in their structure.

Page 206

This is what Russell does with R^* ; he wraps the concept up in such a way that its form disappears.

Page 206

The point of this method is to make everything amorphous and treat it accordingly.

Page 206

If in logic a question can be answered (1) generally and (2) in particular, the particular answer must always show itself to be a special case of the general answer; put differently: the general case must always include the particular as a possibility.

Page Break 207

Page 207

A case of this is the calculation of a limit with δ and ν , which must include the number system of the particular computation.

Page 207

There must be a determinate way for translating the general form and the particular form into one another.

Page 207

171 Any proof of the continuity of a function must relate to a numerical scale--a number system.

Page 207

For if I say, 'Given any ν there is a δ for which the function is less than ν ', I am *ipso facto* referring to a general arithmetical criterion that indicates when $\phi(\delta)$ is less than ν .

Page 207

It is impossible that what in the nature of this case comes to light when calculating the function--namely, the numerical scale should be allowed to disappear in the general treatment.

Page 207

If the numerical system belongs to the essence of number, then the general treatment cannot do away with it.

Page 207

And if, therefore, the notation of the numerical system reflects the essence of number, then this essential element must also find its way into the general notation. In this way the general notation acquires the structure of the numbers.

Page 207

If, in the nature of the case, I cannot write down a number independently of a number system, that must also be reflected in the general treatment of number.

Page 207

A number system is not something inferior--like a Russian abacus--that is only of interest to elementary schools, while the higher, general discussion can afford to disregard it.

Page 207

The Cretan liar paradox could also be set up with someone writing the proposition: 'This proposition is false'. The demonstrative takes over the role of the 'I' in 'I'm lying'. The basic mistake

Page Break 208

consists, as in the previous philosophy of logic, in assuming that a word can make a sort of allusion to its object (point at it from a distance) without necessarily going proxy for it.

Page 208

So the question would really be: Can the continuum be described? As Cantor and others tried to do.

Page 208

A form cannot be described: it can only be presented.

Page 208

Dedekind's definition of an infinite set is another example of an attempt to describe the infinite, without *presenting* it.

Page 208

It would be like describing an illness by the external symptoms we know always accompany it. Only in this case there is a connection which isn't formal in nature.

Page 208

172 'The highest point of a curve' doesn't mean 'the highest point among all the points of the curve'--after all, we don't see these--it is a specific point yielded by the curve. In the same way the maximum of a function isn't the

largest value among all its values (that's nonsense, save in the case of finitely many, discrete points), it's a point yielded by a law and a condition; which, to be sure, is higher than any other point taken at random (*possibility*, not reality). And so also the point of intersection of two lines isn't the common member of two classes of points, it's the meeting of two laws. As indeed is perfectly clear in analytic geometry.

Page 208

The maximum of a function is susceptible of an intensional explanation. The highest point of a curve is admittedly higher than any other point taken at random, but I don't find it by sifting through the points of the curve one by one, looking for a yet higher one.

Page 208

Here again it is grammar which, as always in the sphere of the infinite, is playing tricks on us.

Page Break 209

Page 209

We say 'the highest point of the curve'. But that can't mean 'the highest point of all the points in the curve' in the sense in which we talk of the largest of these three apples, since we don't have all the points of the curve before us--in fact that's a nonsense expression.

Page 209

It's the same defect in our syntax which presents the proposition 'The apple may be divided into two parts' as of the same form as 'a length may be divided without limit', with the result that we can apparently say in both cases, 'Let's suppose the possible division to have been carried out'.

Page 209

But in truth the expressions 'divisible into two parts' and 'divisible without limit' have completely different forms.

Page 209

This is, of course, the same case as the one in which someone operates with the word 'infinite' as if it were a number word; because, in everyday speech, both are given as answers to the question 'How many?'

Page 209

The curve exists, independently of its individual points. This also finds expression in the fact that I *construct* its highest point: that is, derive it from a law and not by examining individual points.

Page 209

We don't say 'among *all* its points, there is only one at which it intersects the straight line'; no, we only talk about *one* point.

Page 209

So to speak, about one that runs along the straight line, but not about one among all the points of the line.

Page 209

The straight line isn't *composed* of points.

Page 209

173 But then what would a correct, as opposed to an amorphous explanation of R^* be like? Here I do need '(n)...'. In this case, this expression seems to be admissible.

Page 209

But, to be sure, ' $(\exists x) \cdot \phi x$ ' also says 'There is a number of x satisfying ϕx ', and yet the expression ' $(\exists x) \cdot \phi x$ ' can't be taken to presuppose the totality of all numbers.

Page 209

Ramsey's explanation of infinity also is nonsense for the same reason, since ' $(n):(\exists nx) \cdot \phi x$ ' would presuppose that we were given

Page Break 210

the actual infinite and not merely the unlimited possibility of going on [$\dagger 1$].

Page 210

But is it inconceivable that I should know someone to be my ancestor without having *any* idea at what remove, so that *no* limits would be set to the number of people in between [$\dagger 2$].

Page 210

But how would we put the proposition: ' ϕ is satisfied by the same number of objects as ψ '? One would suppose: ' $(\exists n):(\exists nx) \cdot \phi x \cdot (\exists nx) \cdot \psi x$ '.

Page 210

Brouwer is right when he says that the properties of his pendulum number are incompatible with the law of the excluded middle. But, saying this doesn't reveal a peculiarity of propositions about infinite aggregates. Rather, it

is based on the fact that logic presupposes that it cannot be *a priori*--i.e. logically--impossible to tell whether a proposition is true or false. For, if the question of the truth or falsity of a proposition is *a priori* undecidable, the consequence is that the proposition loses its sense and the consequence of this is precisely that the propositions of logic lose their validity for it.

Page 210

Just as in general the whole approach that if a proposition is valid for one region of mathematics it need not necessarily be valid for a second region as well, is quite out of place in mathematics, completely contrary to its essence. Although these authors hold

Page Break 211

just this approach to be particularly subtle, and to combat prejudice.

Page 211

Mathematics is ridden through and through with the pernicious idioms of set theory. *One* example of this is the way people speak of a line as composed of points. A line is a law and isn't composed of anything at all. A line as a coloured length in visual space can be composed of shorter coloured lengths (but, of course, not of points). And then we are surprised to find, e.g., that 'between the everywhere dense rational points' there is still room for the irrationals! What does a construction like that for $\sqrt{2}$ show? Does it show how there is yet room for this point in between all the rational points? It merely shows that the point *yielded* by the construction is *not rational*.

Page 211

And what corresponds to this construction and to this point in arithmetic? A sort of number which manages *after all* to squeeze in between the rational numbers? A law that is not a law of the nature of a rational number.

Page 211

The Dedekind cut proceeds as if it were clear what was meant when one says: There are only three cases: either R has a last member and L a first, or, etc. In truth none of these cases can be conceived (or imagined).

Page 211

174 Set theory is wrong because it apparently presupposes a symbolism which doesn't exist instead of one that does exist (is alone possible). It builds on a fictitious symbolism, therefore on nonsense.

Page 211

There is no such thing as an hypothesis in logic.

Page 211

When people say 'The set of all transcendental numbers is greater than that of algebraic numbers', that's nonsense. The set is of a different kind. It isn't 'no longer' denumerable, it's simply not denumerable!

Page Break 212

Page 212

The distribution of primes would then for once provide us with something in logic that a god could know and we couldn't. That is to say, there would be something in logic that could be known, but not by us.

Page 212

That there is a process of solution is something that cannot be asserted. For, were there none, the equation, as a general proposition, would be nonsensical.

Page 212

We can assert anything which can be checked in practice.

Page 212

It's a question of the possibility of checking.

Page 212

If someone says (as Brouwer does) that for $(x) \bullet f_1x = f_2x$, there is, as well as yes and no, also the case of undecidability, this implies that '(x)...' is meant extensionally and we may talk of the case in which all x happen to have a property. In truth, however, it's impossible to talk of such a case at all and the '(x)...' in arithmetic cannot be taken extensionally.

Page 212

We might say, 'A mathematical proposition is a pointer to an insight'. The assumption that no insight corresponded to it would reduce it to utter nonsense.

Page 212

We cannot *understand* the equation unless we recognize the connection between its two sides.

Page 212

Undecidability presupposes that there is, so to speak, a subterranean connection between the two sides; that

the bridge *cannot* be made with symbols.

Page 212

A connection between symbols which exists but cannot be represented by symbolic transformations is a thought that cannot be thought. If the connection is there, then it must be possible to see it.

Page 212

For it *exists* in the same way as the connection between parts of visual space. It isn't a *causal* connection. The transition isn't

Page Break 213

produced by means of some dark speculation different in kind from what it connects. (Like a dark passage between two sunlit places.)

Page 213

Of course, if mathematics were the natural science of infinite extensions of which we can never have exhaustive knowledge, then a question that was in principle undecidable would certainly be conceivable.

Page 213

175 Is there a sense in saying: 'I have as many shoes as the value of a root of the equation $x^3 + 2x - 3 = 0$ '? Even if solving it were to yield a positive integer?

Page 213

For, on my view, we would have here a notation in which we cannot immediately tell sense from nonsense.

Page 213

If one regards the expression 'the root of the equation $\phi x = 0$ ' as a Russellian description, then a proposition about the root of the equation $x + 2 = 6$ must have a different sense from one saying the same about 4.

Page 213

I cannot use a proposition before knowing whether it makes sense, whether it is a proposition. And this I don't know in the above case of an unsolved equation, since I don't know whether cardinal numbers correspond to the roots in the prescribed manner. It is clear that the proposition in the given case becomes nonsense and not false (not even a contradiction), since 'I have n shoes and $n^2 = 2$ ' is obviously tantamount to 'I have $\sqrt{2}$ shoes'.

Page 213

But I can establish this--or at any rate it can be established--if we only look at the signs. But I mustn't chance my luck and incorporate the equation in the proposition, I may only incorporate it if I know that it determines a cardinal number, for in that case it is simply a different notation for the cardinal number. Otherwise, it's just like throwing the signs down like so many dice and leaving it to chance whether they yield a sense or not.

Page Break 214

Page 214

$(x + y)^2 = x^2 + y^2 + 2xy$ is correct in the same sense as $2 \times 2 = 4$.

Page 214

And $2 + n = 1$ (where n is a cardinal number) is just as wrong as $2 + 3 = 1$ and $2 + n \neq 1$ as correct as the above.

Page 214

176 What makes one dubious about a purely internal generality is the fact that it can be refuted by the occurrence of a single case (and so by something extensional).

Page 214

But what sort of collision is there here between the general and the particular proposition? The particular case refutes the general proposition from within, not in an external way.

Page 214

It attacks the internal proof of the proposition and refutes it thus--not in the way that the existence of a one-eyed man refutes the proposition 'Every man has two eyes'.

Page 214

' $(x) \cdot x^2 = x + x$ ' seems to be false because working out the equation gives $x = \begin{Bmatrix} 0 \\ 2 \end{Bmatrix}$ and not that the two sides cancel out. Trying the substitution $x = 3$, say, also yields the general result-- $(\exists x) \cdot x^2 \neq 2x$ --and so must, to the extent that its result tallies with that of the general solution, itself tally with the general method.

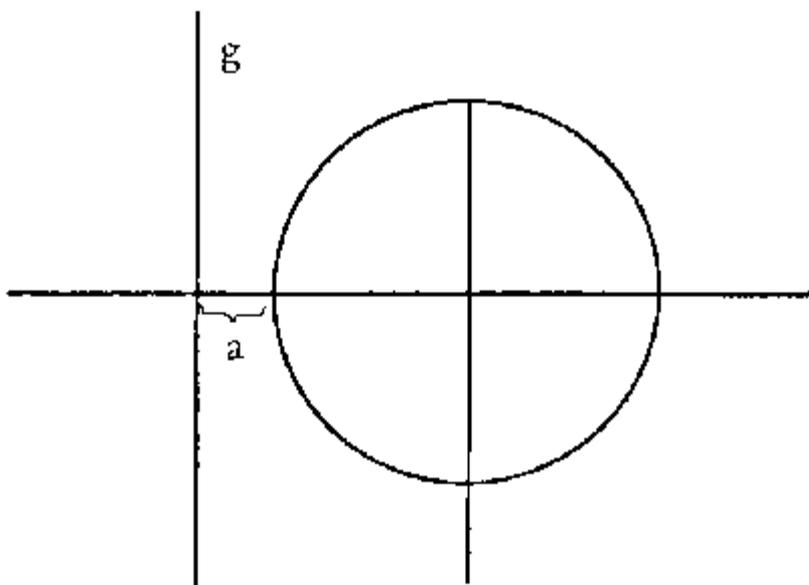

Page 214

If the equation $x^2 + 2x + 2 = 0$ yields, by applying the algebraic rules, $x = -1 \pm \sqrt{-1}$, that is quite in order so long as we don't require the rules for x to accord with the rules for real numbers. In that case the outcome of the algebraic calculation means that the equation has no solution.

My difficulty is: When I solve equations in the real, rational or whole number domain by the appropriate rules, in certain cases I arrive at apparent nonsense. Now, when that happens: am I to say this proves that the original equation was nonsense? Which would mean I could only see whether it was sense or nonsense after I had finished applying the rules?! Isn't what we have to say, rather: The result of the apparently nonsensical equation does

after all show something about the general form, and does indeed establish a connection between the forbidden equation and equations which have a normal solution. After all, the solution always does show the distance of the abnormal solution from a normal one. If, e.g., $\sqrt{-1}$ is the result, I at least know that $\sqrt{-1+1}$ would be a normal root. The continuity, the connection with the normal solution, has not been disrupted. Would this imply that in the concept of the real numbers as we represent it in our symbolism and its rules, the concept of the imaginary numbers is already prefigured?

That would amount to roughly the same thing as saying of a straight line g that it is a distance a away from cutting the circle, instead of simply saying it doesn't cut it.

One might say 'It fails to intersect it by a certain amount' and this would represent the continuity with normal intersection. 'It misses it by a certain amount.'

The difference between the two equations $x^2 = x \cdot x$ and $x^2 = 2x$ isn't one consisting in the extensions of their validity.

I can, it is true, define $m > n$ as $(\exists x) \cdot n + x = m$, but I only know whether $x = m - n$ yields a number if I know the rule for subtraction, and in this context this does duty for the rule for determining greater and less. Thus formulated, this rule runs: m is greater than n , if, according to the rule for subtraction, $m - n$ yields a number.

XVI

177 What makes it apparent that space is not a collection of points, but the realization of a law?

It seems as though we should have first to erect the entire structure of space without using propositions; and then one may form all the correct propositions within it.

In order to represent space we need--so it appears to me--something like an expansible sign.

A sign that makes allowance for an interpolation, similar to the decimal system.

The sign must have the multiplicity and properties of space.

Page 216

The axioms of a geometry are not to include any truths.

Page 216

We can be sure of getting the correct multiplicity for the designations if we use analytic geometry.

Page 216

That a point in the plane is represented by a number-pair, and in three-dimensional space by a number-triple, is enough to show that the object represented isn't the point at all but the point-network.

Page 216

178 The geometry of visual space is the syntax of the propositions about objects in visual space.

Page 216

The axioms--e.g.--of Euclidean geometry are the disguised rules of a syntax. This becomes very clear if you look at what corresponds to them in analytic geometry.

Page 216

You could imagine the constructions of Euclidean geometry actually being carried out, say by using the edges of bodies as straight lines and the surfaces as planes. The axiom--for instance--that a

Page Break 217

straight line can be drawn through any two points has here the clear sense that, although no straight line *is* drawn between any 2 arbitrary points, it is *possible* to draw one, and that only means that the proposition 'A straight line passes through these points' makes *sense*. That is to say, Euclidean geometry is the syntax of assertions about objects in Euclidean space. And these objects are not lines, planes and points, but *bodies*.

Page 217

How are the equations of analysis connected with the results of spatial measurements? I believe, in such a way that they (the equations) fix what is to count as an accurate measurement and what as an error.

Page 217

One could almost speak of an external and an internal geometry. Whatever is arranged in visual space stands in this *sort* of order *a priori*, i.e. in virtue of its logical nature, and geometry here is simply grammar. What the physicist sets into relation with one another in the geometry of physical space are instrument readings, which do not differ in their *internal* nature whether we live in a linear space or a spherical one. That is to say, it isn't an investigation of the logical properties of these readings that leads the physicist to make an assumption about the nature of physical space, but the facts that are derived from them.

Page 217

The geometry of physics in this sense doesn't have to do with possibility, but with the facts. It is corroborated by facts: in the sense, that is, in which a *part* of an hypothesis is corroborated.

Page 217

Comparison between working with an adding machine and measuring geometrical structures: In such measurement, do we perform an experiment, or is the situation here the same as in the case of the adding machine, where we only establish internal relations and the physical result of our operations proves nothing?

Page 217

In visual space, of course, there is no such thing as a geometrical experiment.

Page Break 218

Page 218

I believe this is where the main source of misunderstanding about the *a priori* and the *a posteriori* in geometry lies.

Page 218

The question is, in what sense can the results of measurement tell us something concerning *that* which we also see.

Page 218

What about the proposition 'The sum of the angles of a triangle is 180° '? At any rate, it doesn't give the appearance of a proposition of syntax.

Page 218

The proposition 'Vertically opposite angles are equal' means that if they turn out to be different when they are measured, I shall declare the measurement to be in error; and 'The sum of the angles of a triangle is 180° ' means that, if the sum doesn't turn out to be 180° when measured, I shall assume an error in the measurement. In this way, the proposition is a postulation concerning the way to describe the facts: and so a proposition of syntax.

Page 218

There is obviously a method for constructing a straight ruler. This method involves an ideal: I mean, an approximation procedure with unlimited *possibility*, for it is simply this procedure which *is* the ideal.

Page 218

Or better: Only if it is a procedure with unlimited possibility, can (not must) the geometry of this procedure be Euclidean.

Page 218

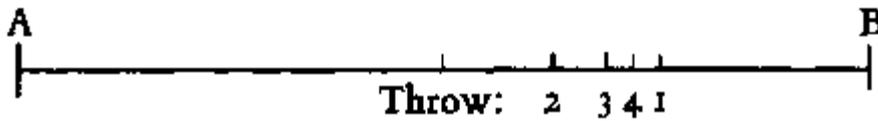

Euclidean geometry doesn't presuppose *any method for measuring* angles and lengths, it no more says when two angles are to be counted as equal, than probability theory says when two cases are to be counted as equally likely. If a particular method of measurement is now adopted--say one with metal rulers--the question then arises whether the results of measurements carried out in this way yield Euclidean results.

Page 218

179 Imagine we are throwing a two-sided die, such as a coin. I now want to determine a point of the interval A B by continually tossing the coin, and always bisecting the side prescribed by the

Page Break 219

throw: say: heads means I bisect the right-hand interval, tails the left-hand one

Page 219

Now, does it describe the position of a point of the interval if I say 'It is *the* point which is approached indefinitely by bisection as prescribed by the endless tossing of the coin'?

Page 219

In this way I can approach without limit every point of the interval by continual bisection, and with infinitely fine eyesight and instruments *every* stage of the bisection would be determined. (The infinitely fine eyesight doesn't introduce a vicious circle.)

Page 219

Now, could we call an infinite series of digits which was thus determined an infinite decimal? That is, does this geometrical process define a *number*?

Page 219

The geometrical process does not involve a vicious circle, since only an infinite possibility is presupposed by it, not an infinite reality. (Lines and points being given by the boundaries of coloured surfaces.)

Page 219

To what extent can you say that I have in this way really divided the rationals into two classes? In fact, of course, this division is never accomplished. But I have a *process* by means of which I approach such a division indefinitely? I have an unlimited process, whose results as such don't lead me to the goal, but whose unlimited possibility is itself the goal. But what does this limitlessness consist in--don't we here have once more merely an operation and the *ad infinitum*? Certainly. But the operation is not an arithmetical one.

Page 219

(And the point which I call to my aid in my endless construction can't be given arithmetically at all.)

Page 219

At this point many people would say: it doesn't matter that the

Page Break 220

method was geometrical, it is only the resulting *extension* itself that is our goal. But, then, do I have this?

Page 220

What is the analogue in arithmetic to the geometrical process of bisection? It must be the converse process: that of determining a point by a law. (Instead of the law by a point.)

Page 220

It would in fact correspond to the endless process of choosing between 0 and 1 in an infinite binary

expansion **0000** **1111** ... *ad inf.* The law here would run 'You must put a 1 or a 0 in succession *ad inf.*, each yields a law, each a different one.'

Page 220

But that doesn't imply that a law would be given *in that* I say 'In every case throw either heads or tails.' Of course, in this way I would necessarily obtain a special case of the general law mentioned, but wouldn't know from

the outset which. No law of succession is described by the instruction to toss a coin.

Page 220

What is arithmetical about the process of tossing the coin isn't the actual result, it is its infinite indefiniteness. But that simply does not *define* a number [†1].

Page 220

If I adumbrate a law thus: '0.001001001... *ad inf.*', what I want to show is not the finite series as a specimen of a section of an infinite series, but rather the kind of regularity to be perceived in it. But in $0.0001111\dots$... I don't perceive *any* law--on the contrary, precisely that a law is absent. Save, say, the law that the results of the specific laws are written with '0' and '1' and no other signs.

Page 220

The rules of combination for 0 and 1 yield the totality of *all* finite

Page Break 221

fractions. This would be an infinite extension, in which the infinite extension of fractions 0.1, 0.101, 0.10101 etc. *ad inf.* would also have to occur and, generally, all the irrational numbers.

Page 221

What is it like if someone so to speak checks the various laws by means of the set of finite combinations?

Page 221

The results of a law run through the finite combinations, and hence the laws are complete as far as their extensions are concerned, once *all* the finite combinations have been gone through.

Page 221

Neither may we say: Two laws are identical in the case where they yield the same result at every stage. No, they are identical if it is of their essence to yield the same result, i.e. if they are identical.

Page 221

180 If an amorphous theory of infinite aggregates is possible, it can describe and represent only what is amorphous about these aggregates.

Page 221

It would then really have to construe the laws as merely inessential devices for representing an aggregate. And abstract from this inessential feature and attend only to what is essential. But to what?

Page 221

Is it possible within the law to abstract from the law and see the extension presented as what is essential?

Page 221

This much at least is clear: that there isn't a dualism: the law and the infinite series obeying it; that is to say, there isn't something in logic like description and reality.

Page 221

Suppose I cut at a place where there is no rational number. Then there *must* surely be approximations to this cut. But what does 'closer to' mean here? *Closer* to what? For the time being I have nothing in the domain of number which I can approach. But I do in the case of a geometrical stretch. Here it is clear I can come arbitrarily close to any non-rational cut. And it is also clear that this is a process without an end and I am shown unambiguously how to go on by the spatial fact.

Page Break 222

Page 222

Once more it is only infinite possibility, but now the law is given in a different way.

Page 222

But can I be in doubt whether all the points of a line can actually be represented by arithmetical rules [†1]. Can I then ever find a point for which I can show that this is not the case? If it is given by means of a construction, then I can translate this into an arithmetical rule, and if it is given by chance, then there is, no matter how far I continue the approximation, an arithmetically defined decimal expansion which is concomitant with it.

Page 222

It is clear that a point corresponds to a rule.

Page 222

What is the situation with regard to types [†2] of rules, and does it make sense to talk of all rules, and so, of all points?

Page 222

In some sense or other there can't be irrational numbers of different types.

My feeling here is the following: no matter how the rule is formulated, in every case I still arrive at nothing else but an endless series of rational numbers. We may also put it like this: no matter how the rule is formulated, when I translate it into geometrical notation, everything is of the same type.

In the case of approximation by repeated bisection, we approach *every* point via *rational* numbers. There is no point which we could only approach with irrational numbers of a specific type.

It is of course possible that in determining a maximum I may stumble upon a new rule, but this has nothing essential to do with determining the maximum; it doesn't refer explicitly to a totality of real numbers.

XVII

181 The question would be: what criterion is there for the irrational numbers being *complete*?

Let us look at an irrational number: it runs through a series of rational approximations. When does it leave this series behind? Never. But then, the series also never comes to an end.

Suppose we had the totality of all irrational numbers with one single exception. How would we feel the lack of this one? And--if it were to be added--how would it fill the gap?--Suppose that it's π . If an irrational number is given through the totality of its approximations, then up to *any* point taken at random there is a series coinciding with that of π . Admittedly, for each such series there is a point where they diverge. But this point can lie arbitrarily far 'out'. So that for any series agreeing with π , I can find one agreeing with it still further. And so if I have the totality of all irrational numbers except π , and now insert π , I cannot cite a point at which π is now really needed. At *every* point it has a companion agreeing with it from the beginning on.

This shows clearly that an irrational number isn't the extension of an infinite decimal fraction, that it's a law.

Somehow it seems to follow from this--and this is something I find very compelling--that infinitely long isn't a measure of distance.

Our answer to the question above must be 'If π were an extension, we would never feel the lack of it', i.e. it would be impossible for us to observe a gap. If someone were to ask us, 'But have you then an infinite decimal expansion with m in the r -th place and n in the s -th place, etc.?', we could always oblige him.

Now let's assume we have been given all the irrational numbers that can be represented by laws, but that there are yet other irrationals, and I am given a cut representing a number not belonging to the first class: How am I to tell that this is so? This is impossible, since no matter how far I go with my approximations, there will always also be a corresponding fraction.

And so we cannot say that the decimal fractions developed in accordance with a law still need supplementing by an infinite set of irregular infinite decimal fractions that would be 'brushed under the carpet' if we were to *restrict* ourselves to those *generated by a law*. Where is there such an infinite decimal that is generated by no law? And how would we notice that it was missing? Where is the gap it is needed to fill?

If from the very outset only laws reach to infinity, the question whether the totality of laws exhausts the totality of infinite decimal fractions can make no sense at all.

The usual conception is something like this: it is true that the real numbers have a different multiplicity from the rationals, but you can still write the two series down alongside one another to begin with, and sooner or later the series of real numbers leaves the other behind and goes infinitely further on.

But my conception is: you can only put finite series alongside one another and in that way compare them;

there's no point in putting dots after these finite stretches (as signs that the series goes on to infinity). Furthermore, you can compare a law with a law, but not a law with *no* law.

Page 224

182 $\overset{5 \rightarrow 3}{\sqrt{2}}$ [$\dagger 1$]: I'm tempted to say, the individual digits are always only the results, the bark of the fully grown tree. What

Page Break 225

counts, or what something new can still grow from, is the inside of the trunk, where the tree's vital energy is. Altering the surface doesn't change the tree at all. To change it, you have to penetrate the trunk which is still living.

Page 225

Thus it's as though the digits were dead excretions of the living essence of the root. Just as when in the course of its vital processes a snail discharges chalk, so building on to its shell.

Page 225

There must first be the rules for the digits, and then--e.g.--a root is expressed in them. But this expression in a sequence of digits only has significance through being the expression for a real number. If someone subsequently alters it, he has only succeeded in distorting the expression, but not in obtaining a new number.

Page 225

The rules for the digits belong at the beginning, as a preparation for the expression.

Page 225

For the construction of the system in which the law lives out its life.

Page 225

183 And so I would say: If ' $\sqrt{2}$ ' is anything at all, then it is the same as $\sqrt{2}$, only another expression for it; the expression in another system.

Page 225

In that case we might also put this quite naively as follows: I understand what ' $\sqrt[4]{2}$ ' means, but not ' $\sqrt{2}$ ', since $\sqrt{2}$ has no places at all, and I can't substitute others for none.

Page 225

How about $1/7$ ($5 \rightarrow 3$)? Of course $0.\dot{1}4283\dot{7}$ isn't an infinite extension but once again an infinite rule, with which an extension

Page Break 226

can be formed. But it is such a rule as can so to speak digest the ($5 \rightarrow 3$).

Page 226

The suffix ($1 \rightarrow 5$) so to speak strikes at the heart of the law $0.1010010001\dots$. The law talks of a 1 and a 5 is to be substituted for this 1.

Page 226

Could we perhaps put it by saying ' $\sqrt{2}$ ' isn't a measure until it is in a system?

Page 226

It's as if a *man* were needed before the rule ' $\sqrt{2}$ ' could be carried out. Almost: if it's to be of any concern to arithmetic, the rule itself must understand *itself*. The rule ' $\sqrt{2}$ ' doesn't do this, it is made up out of two heterogeneous parts. The man applying it puts these parts together [$\dagger 1$].

Page 226

Does this mean that the rule ' $\sqrt{2}$ ' lacks something, viz. the connection between the system of the root and the system of the sequence of digits?

Page 226

You would no more say of ' $\sqrt{2}$ ' that it is a limit towards which the values of a series were tending, than you would of the instruction to throw dice.

Page 226

How far does $\sqrt[4]{2}$ have to be expanded for us to have some acquaintance with it? This of course means nothing. So we are already acquainted with it without its having been expanded at all. But in that case ' $\sqrt{2}$ ' doesn't mean a thing.

The idea behind $\sqrt{2}$ is this: we look for a rational number which, multiplied by itself, yields 2. There isn't one. But there are those which in this way come close to 2 and there are always some which approach 2 more closely still. There is a procedure permitting me to approach 2 indefinitely closely. This procedure is itself something. And I call it a real number.

It finds expression in the fact that it yields places of a decimal fraction lying ever further to the right.

Only what can be foreseen about a sequence of digits is essential to the real number.

184 That we can apply the law, holds also for the law to throw the digits like dice.

And what distinguishes π' from this can only be its arithmetical definiteness. But doesn't that consist in our knowing that there must be a law governing the occurrences of the digit 7 in π ; even if we don't yet know what this law is?

And so we could also say: π' alludes to a law which is as yet unknown (unlike $1/7$).

But mightn't we now say: π contains the description of a law 'the law in accordance with which 7 occurs in the expansion of π '? Or would this allusion only make sense if we knew how to derive this law? (Solution of a mathematical problem.)

In that case I confessedly cannot simply read this law off from the prescription, and so the law in it is contained in a language I can't read. And so in this sense too I don't understand π' .

But then how about the solubility of the problem of finding this law? Isn't it only a problem in so far as we *know* the method for solving it?

And if it is known, precisely *that* gives π' its sense, and if

unknown, we can't speak about the law which we don't yet know, and π' is bereft of all sense. For if no law presents itself, π' becomes analogous to the instruction to follow the throws of dice.

185 A real number lives in the substratum of the operations out of which it is born.

We could also say: " $\sqrt{2}$ " means the method whereby x^2 approximates to 2.

Only a path approaches a goal, positions do not. And only a law approaches a value.

x^2 approaching 2, we call x approaching $\sqrt{2}$.

186 The letter π stands for a law. The sign π' (or: $\overset{7 \rightarrow 3}{\pi}$) means nothing, if there isn't any talk of a 7 in the law for π , which we could then replace by a 3. Similarly for $\overset{3 \rightarrow 5}{\sqrt{2}}$. (Whereas $\overset{2 \rightarrow 5}{\sqrt{2}}$ might mean $\sqrt{5}$).

A real number *yields* extensions, it is not an extension.

A real number is: an arithmetical law which endlessly yields the places of a decimal fraction.

This law has its position in arithmetical space. Or you might also say: in algebraic space.

Whereas π' doesn't use the idioms of arithmetic and so doesn't assign the law a place in this space.

Page 228

It's as though what is lacking is the arithmetical creature which produces these excretions.

Page 228

The impossibility of comparing the sizes of π and π' ties in with this homelessness of π' .

Page 228

You cannot say: two real numbers are identical, if all their places coincide. You cannot say: they are different, if they disagree in one

Page Break 229

of the places of their expansion. No more can you say the one is greater than the other if the first place at which they disagree is greater for the first than the second.

Page 229

Suppose someone were to invent a new arithmetical operation, which was normal multiplication, but modified so that every 7 in the product was replaced by a 3. Then the operation \times' would have something about it we didn't understand so long as we lacked a law through which we could understand the occurrence of 7 in the product in general.

Page 229

We would then have here the extraordinary fact that my symbolism would express something I don't understand. (But that is absurd.)

Page 229

It is clear that were I able to apply \times' all doubts about its legitimacy would be dispelled. For the possibility of application is the real criterion for arithmetical reality.

Page 229

Even if I wasn't already familiar with the rule for forming $\sqrt{2}$, and I took $\overset{7 \rightarrow 3}{\sqrt{2}}$ to be the original prescription, I would still ask: what's the idea of this peculiar ceremony of replacing 7 by 3? Is it perhaps that 7 is tabu, so that we are forbidden to write it down? For substituting 3 for 7 surely adds absolutely nothing to the law, and in this system it isn't an arithmetical operation at all.

Page 229

Put geometrically: it's not enough that someone should--supposedly--determine a point ever more closely by narrowing down its whereabouts; we must be able to construct *it*.

Page 229

To be sure, continual throwing of a die indefinitely restricts the possible whereabouts of a point, but it doesn't determine a point.

Page 229

After *every* throw the point is still infinitely indeterminate.

Page 229

Admittedly, even in the course of extracting a root in the usual way, we constantly have to apply the rules of multiplication

Page Break 230

appropriate at that point, and their application has also not been anticipated. But neither is there any mention of them and their application in the principle of $\sqrt{2}$.

Page 230

A number must measure. And this doesn't mean merely: values in its expansion must measure. For we can't talk of *all* values, and that rational numbers (which I have formed in accordance with some rule) measure goes without saying.

Page 230

What I mean might be put like this: for a real number, a construction and not merely a process of approximation must be conceivable.--The construction corresponds to the unity of the law.

Page 230

187 $\overset{10:3}{10} = 0.\overset{3}{3}$. That we come full circle is what I actually see and express by means of $\overset{3}{3}.\overset{3}{3}$ doesn't mean 'nothing but 3s come', but 'a 3 must recur again and again'.

Page 230

Understanding the rule and how to carry it out in practice always only helps us over finite stretches. To determine a real number it must be completely intelligible *in itself*. That is to say, it must not be essentially undecided whether a part of it could be dispensed with.

For in that case it simply isn't clearly given, for there is no extension which would be equivalent to it, and in itself it is indeterminate. π in that case sets out to seek its fortune in infinite space.

Of course, if a and b do not agree for the first time at the fourth place, we can say that therefore they are unequal. This fourth place clearly does belong to both numbers; but not the indefinite n th place in the infinite progression.

Thus we can certainly tell that π and e are different from the difference in their *first* place. But we can't say that they would be equal, if all their places were equal.

If the extensions of two laws coincide as far as we've gone, and I cannot compare the laws as such, the numbers defined, if I have any right to talk of such numbers, cannot be compared, and the question which is greater or whether they are equal is nonsense. Indeed, an equation between them must be nonsense. And that gives one pause for thought. And it's true: we cannot mean anything by equating them, if there is no inner connection between them; if they belong to different systems. (And the extension is of no use to us.)

But then, are what can't be compared with one another really *numbers*?

Doesn't that contradict the simple image of the number line?

188 There is no number outside a system.

The expansion of π is simultaneously an expression of the nature of π and of the nature of the decimal system.

Arithmetical operations only use the decimal system as a means to an end; that is, the rules for the operations are of such a kind that they can be translated into the language of any other number system, and do not have any of them as their *subject matter*.

The expansion of π is admittedly an expression both of the nature of π and of the decimal notation, but our interest is usually restricted exclusively to what is essential to π , and we don't bother about the latter. That is a servant which we regard merely as a tool and not as an individual in its own right. But if we now regard it as a member of society, then that alters society.

A general rule of operation gets its generality from the generality of the alteration it effects in the numbers.

That is why $\overset{7 \rightarrow 3}{\times}$ won't do as a general rule of operation, since the result of $a \overset{7 \rightarrow 3}{\times} b$ doesn't

depend solely on the nature of the numbers a and b ; the decimal system also comes in. Now, that wouldn't matter, of course, if this system underlay the operation as a further constant $(\sum \frac{1}{100^n})$, and we can certainly find an operation that corresponds to \times : which then has not only a and b but also the decimal system as its *subject-matter*. This operation will be written in a number system which withdraws itself as a servant into the background, and of which there is no mention in the operation.

In just this way $\overset{7 \rightarrow 3}{\pi}$ makes the decimal system into its subject matter (or would have to do so, if it were genuine), and for that reason it is no longer sufficient that we can use the rule to form the extension. For this application has now ceased to be the criterion for the rule's being in order, since it is not the expression of the arithmetical law at all, but only makes a superficial alteration to the language.

And so, if the decimal system is to stop being a servant, it must join the others at table, observing all the required forms, and leave off serving, since it can't do both at once.

This is how it is: the number π is expressed in the decimal system. You can't achieve a modification of this law by fixing on the specific expression in the decimal system. What you thereby influence isn't the law, it's its accidental expression. The influence does not penetrate as far as the law at all. Indeed it stands separated from it on the other side. It's like trying to influence a creature by working on a secretion that has already been discharged.

Page 232

$$\sum_{p=1}^{p=p} \frac{1}{10^p}$$

189 What about a law $p=1$, (where p runs through the series of primes)? Or where p runs through the series of whole numbers except for those for which the equation of Fermat's Last Theorem doesn't hold.--Do these laws define real numbers?

Page 232

I say: the so-called 'Fermat's Last Theorem' isn't a proposition [\dagger 1]. (Not even in the sense of a proposition of arithmetic.) Rather, it

Page Break 233

corresponds to a proof by induction. Now, if there is a number $F = 0.110000$ etc., and that proof succeeds, that would surely prove that $F = 0.11$ --and isn't that a proposition?! Or: it is a proposition, if the law F is a number.

Page 233

A proof proves what it proves and no more.

Page 233

$$\sum_{n=1}^{n=n} \frac{1}{10^n}$$

The number F wants to use the spiral $n=1$ and choose sections of this spiral according to a principle. But this principle doesn't belong to the spiral.

Page 233

If I imagine the windings of the spiral

$$1/10^0, 1/10^0 + 1/10^1, 1/10^0 + 1/10^1 + 1/10^2, \text{ etc.}$$

to have been written out, then the number F makes a comment on each winding, it puts a tick or a cross against each one; and, what's more, making its choices *according to a law we don't know*.

Page 233

And this is how we arrive at the paradox that it's nonsense to ask whether $F = 0.11$. For, accepting F depends upon accepting the assumption of a law, an infinite law, which governs the behaviour of the numbers in the Fermat formula.--But what indicates to us the infinity of the law? Only the induction. And where is that to be found here? In the infinite possibility of the exponent n in $x^n + y^n = z^n$, and so in the infinite possibility of making tests. But that doesn't have any different value for us from that of the infinite possibility of throwing dice, since we don't know a law to which the *results* of such tests would conform.

Page 233

There is admittedly a law there (and so also an arithmetical interest), but it doesn't refer directly to the number. The number is a sort of lawless by-product of the law. As though someone went along the street at a regulation pace, throwing a die at every pace, and constantly either putting a peg in the ground or not, as directed by the fall of the die; in this case these pegs wouldn't be spaced out in accordance with a law.

Page Break 234

Page 234

Or rather, the law spacing them would only be that governing the strides and no other.

Page 234

Does it then make no sense to say, even after Fermat's Last Theorem has been proved, that $F = 0.110$? (If, say, I were to read about it in the papers.)

Page 234

The true nature of real numbers must be the induction. What I must look at in the real number, its sign, is the induction.--The 'So' of which we may say 'and so on'. If the law, the winding of the spiral, is a number, then it must be comparable with all the others through its position (on the number scale).

Page 234

I certainly do not define that position by means of anything but the law.

Only what I see, is a law; not what I *describe*.

I believe that is the only thing standing in the way of my expressing more by my signs than I can understand.

XVIII

190 In this context we keep coming up against something that could be called an 'arithmetical experiment'. Admittedly the data determine the result, but I can't see *in what way* they determine it. (cf. e.g. the occurrences of 7 in π .) The primes likewise come out from the method for looking for them, as the results of an experiment. To be sure, I can convince myself that 7 is a prime, but I can't see the connection between it and the condition it satisfies.--I have only found the number, not generated it.

I look for it, but I don't generate it. I can certainly see a law in the rule which tells me how to find the primes, but not in the numbers that result. And so it is unlike the case $+ 1/1!$, $- 1/3!$, $+ 1/5!$, etc., where I can see a law *in the numbers*.

I must be able to write down a part of the series, in such a way that you can *recognize* the law.

That is to say, no *description* is to occur in what is written down, everything must be represented.

The approximations must themselves form what is *manifestly* a series.

That is, the approximations themselves must obey a law.

Can we say that unless I knew the geometrical representation of π and $\sqrt{2}$, I would only have an approximate knowledge of these numbers? Surely not.

191 A number must measure in and of itself.

It seems to me as though that's its job.

If it doesn't do that but leaves it to the rationals, we have no need of it.

It seems to be a good rule that what I will call a number is that which can be compared with any rational number taken at random. That is to say, that for which it can be established whether it is greater than, less than, or equal to a rational number.

That is to say, it makes sense to call a structure a number by analogy, if it is related to the rationals in ways which are analogous to (of the same multiplicity as) greater, less and equal to.

A real number is what can be compared with the rationals.

When I say I call irrational numbers only what can be compared with the rationals, I am not seeking to place too much weight on the mere stipulation of a name. I want to say that this is precisely what has been meant or looked for under the name 'irrational number'.

Indeed, the way the irrationals are introduced in text books always makes it sound as if what is being said is: Look, that isn't a rational number, but still there is a number there. But why then do we still call what *is* there 'a number'? And the answer must be: because there is a definite way for comparing it with the rational numbers.

'The process would only define a number when it has come to an end, but since it goes on to infinity and is never complete, it *doesn't* define a number.'

The process must have infinite foresight, or else it won't define a number. There must be no 'I don't as yet know', since there's no 'as yet' in the infinite.

Page 236

Every rational number must stand in a visible relation to the law which is a number.

Page 236

The true expansion is just the method of comparison with the rationals.

Page Break 237

Page 237

The true expansion of a number is the one which permits a direct comparison with the rationals.

Page 237

If we bring a rational number into the neighbourhood of the law, the law must give a definite reaction to it.

Page 237

It must reply to the question 'Is it *this* one?'

Page 237

I should like to say: The true expansion is that which evokes from the law a comparison with a rational number.

Page 237

Narrowing down the interval of course contributes to the comparison through the fact that every number thereby comes to lie to the left or right of it.

Page 237

This only holds when comparing the law with a given rational number forces the law to declare itself in comparison with this number.

Page 237

192 A real number can be compared with the fiction of an infinite spiral, whereas structures like F , $P[\dagger 1]$, or π only with finite sections of a spiral.

Page 237

For my inability to establish on which side it passes by a point, simply means that it is absurd to compare it with a complete (whole) spiral, for with that I would see how it goes past the point.

Page 237

You see, at the back of our minds here, we always have the idea that while I don't know the spiral as a whole, and so don't know what its path is at this point, what I don't know is still in fact thus or so.

Page 237

193 If I say $(\sqrt{\frac{1}{n} 2})^2$ approaches 2 and so eventually reaches the numbers 1.9, 1.99, 1.999, that is nonsense unless I can state within how many stages these values will be reached, for 'eventually' means nothing.

Page 237

To compare rational numbers with $\sqrt{2}$, I have to square them.--They then assume the form \sqrt{a} , where \sqrt{a} is now an arithmetical operation.

Page 237

Written out in this system, they can be compared with $\sqrt{2}$, and it is for me as if the spiral of the irrational number had shrunk to a point.

Page Break 238

Page 238

We don't understand why there is a 4 at the third decimal place of $\sqrt{2}$, but then we don't *need* to understand it.--For this lack of understanding is swallowed up in the wider (consistent) use of the decimal system.

Page 238

In fact, in the end the decimal system as a whole withdraws into the background, and then only what is essential to $\sqrt{2}$ remains in the calculation.

Page 238

194 Is an arithmetical experiment still possible when a recursive definition has been set up? I believe, obviously not; because via the recursion each stage becomes arithmetically comprehensible.

Page 238

And in recursion we do not start from another generality, but from a particular arithmetical case.

A recursive definition conveys understanding by building on one particular case that presupposes no generality.

To be sure, I can give a recursive explanation of the rule for investigating numbers in the cases $([†1], F, \text{ and } P)$, but not of the outcome of such investigation. I cannot construct the result.

Let $\rightarrow 4$ mean: 'The fourth prime number'. Can $\rightarrow 4$ be construed as an arithmetical operation applied to the basis 4? So that $\rightarrow 4 = 5$ is an equation of arithmetic, like $4^2 = 16$?

Or is it that $\rightarrow 4$ can 'only be sought, but not constructed'?

195 Is it possible to prove a greater than b , without being able to prove at which place the difference will come to light? I think not.

How many noughts can occur in succession in e ? If the n th decimal place is followed by a 0, and if it is fixed after $n + r$ stages of the summation $[†1]$ then the 0 must be fixed at the same time as the n th place, for another number can only give way to an 0, if the place preceding it also still changes. Thus the number of noughts is limited.

We can and must show the decimal places to be fixed after a *definite* number of stages.

If I don't know how many 9s may follow after 3.1415, it follows that I can't specify an interval smaller than the difference between π and 3.1416; and that implies, in my opinion, that π doesn't correspond to a point on the number line, since, if it does correspond to a point, it must be possible to cite an interval which is smaller than the interval from this point to 3.1416.

If the rational number with which I want to compare my real number is given in decimal notation, then if I am to carry out the comparison I must be given a relation between the law of the real number and the decimal notation.

1.4--Is that the square root of 2? No, it's the root of 1.96. That is, I can immediately write it in the form of an approximation to $\sqrt{2}$; and of course, see whether it is an approximation above or below $[†2]$.

What is an approximation? (Surely all rational numbers lie either above or below the irrational number.) An approximation is a rational number written in such a form that it can be compared with the irrational number.

In that case, decimal expansion is a method of comparison with

the rationals, if it is determined in advance how many places I must expand to in order to settle the issue.

196 A number as the result of an arithmetical experiment, and so the experiment as the *description* of a number, is an absurdity.

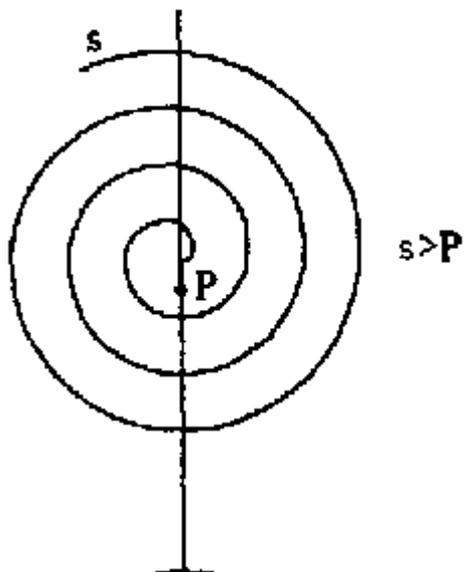

The experiment would be the description, not the *representation* of a number.

I *cannot* compare F with $11/100$, and so it isn't a number.

If the real number is a rational number a , comparison of its law with a must show this. That means the law must be so formed as to 'click into' the rational number when it comes to the appropriate place (this number).

It wouldn't do, e.g., if we couldn't be sure whether $\sqrt{25}$ really breaks off at 5.

We might also put it like this: the law must be such that any rational number can be inserted and tried out.

Page 240

But in that case what about a number like $P = 0.11101010001$ etc.? Suppose someone claimed it was a recurring decimal, and also at some stage or other it looked as if it were, then I would have to be able to try out the supposed number in the law, just as I can see directly by multiplication whether 1.414 is $\sqrt{2}$. But that isn't possible.

Page 240

The mark of an arithmetical experiment is that there is something opaque about it.

Page Break 241

Page 241

197 A *subsequent* proof of convergence cannot justify construing a series as a number.

Page 241

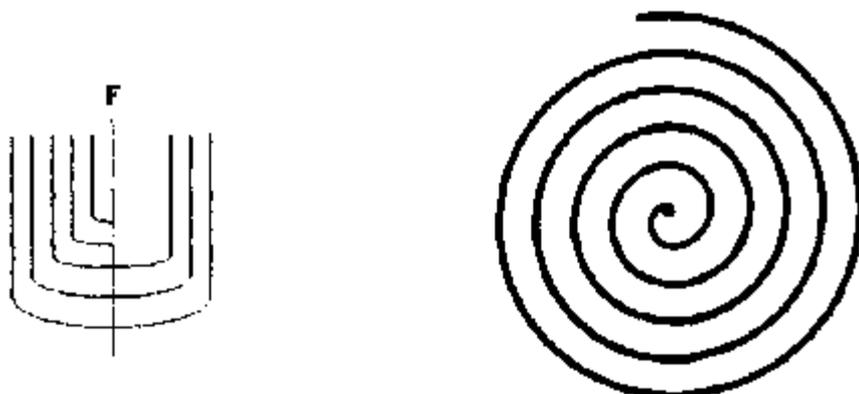

Where a convergence *reveals* itself, that is where the number must be sought.

Page 241

A proof showing something has the properties necessary to a number, must *indicate* the number. That is, the proof is simply what points the number out.

Page 241

Isn't F also an unlimited contraction of an interval? [\dagger 1]

Page 241

How can I know that or whether the spiral will not focus on this point? In the case of $\sqrt{2}$ I do know.

Page 241

Now, can I also call such a spiral a number? A spiral which can, for all I know, come to a stop at a rational point.

Page 241

But that isn't possible either: there is a lack of a *method* for comparing with the rationals.

Page 241

For developing the extension isn't such a method, since I can never know if or when it will lead to a decision.

Expanding indefinitely isn't a method, even when it leads to a

result of the comparison.

Whereas squaring a and seeing whether the result is greater or less than 2 is a method.

Could we say: what is a real number is the *general method* of comparison with the rationals?

It must make sense to ask: 'Can this number be π '?

198 F is not the interval $0-0.1$; for I can also make a certain decision within this interval, but it isn't a number inside this interval, since we can't force the issues that would be necessary for that.

Might we then say: F is certainly an arithmetical structure, only not a number (nor an interval)?

That is, I can compare F neither with a point nor with an interval. Is there a geometrical structure to which that corresponds?

The law, i.e. the method of comparison, only says that it will yield either the answers 'greater, less or equal'--or--'greater' (but not equal). As though I go into a dark room and say: I can only find out whether it is lower than I am or the same height--or--higher. And here we might say: and so you can't find out a height; and so what is it you can find out? The comparison only goes lame because I can surely establish the height if I bump my head, whereas, in the case of F , I cannot, in principle, ask: 'Is it this point?'

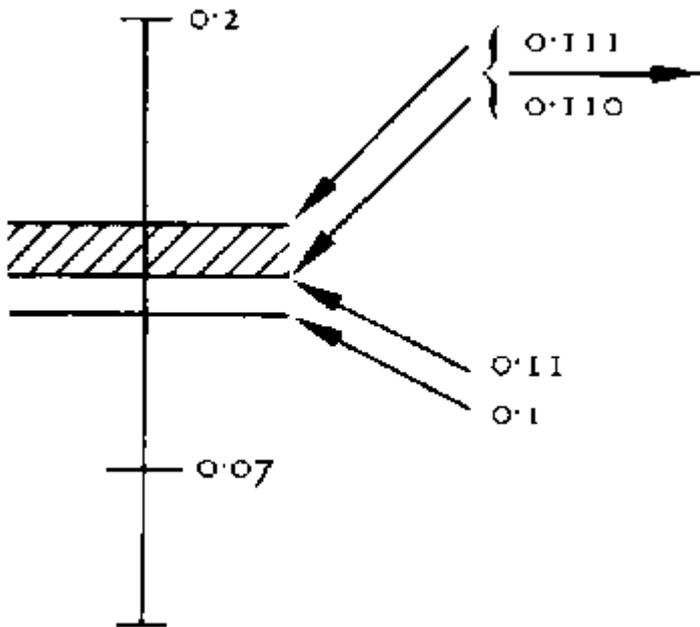

I don't know a method for determining whether it is this point, and so it isn't a point.

If the question how F compares with a rational number has no sense, since all expansion still hasn't given us an answer, then this question also had no sense before we tried to settle the question at random by means of an extension.

If it makes no sense now to ask 'Does $F = 0.11$ '?', then it had no

sense even before people examined 100 places of the extension, and so even before they had examined only one.

But then it would make no sense at all to ask in this case whether the number is equal to *any* rational number whatsoever. As long, that is, as we don't possess a method which necessarily settles the question.

Page 243

This is as much as I know to date about the 'number'.

Page 243

The rational number given is either equal to, less than or greater than the interval that has so far been worked out. In the first case the point forms the lower end point of the interval, in the second it lies below, in the third, above the interval. In none of these cases are we talking about comparing the positions of two points.

Page 243

199 $0.\dot{3}$ is not a result of $1/3$ in the same sense as, say, 0.25 is of $1/4$; it points to a different arithmetical fact.

Page 243

Suppose the division continually yielded the same digit, 3, but without our seeing in it the necessity for this, would it then make sense to form the conjecture that the result will be $0.\dot{3}$?

Page 243

That is, doesn't $0.\dot{3}$ simply designate an induction we have seen and not--an extension?

Page 243

We must always be able to determine the order of magnitude. Suppose (in my notation) nothing speaks against 100 threes following in succession in e at a particular point, then something

Page Break 244

speaks against 10^{100} threes doing so. (A great deal must be left open in the decimal system, that is definite in the binary system.)

Page 244

It isn't only necessary to be able to say whether a given rational number is the real number: we must also be able to say how close it can possibly come to it. That is, it isn't enough to be able to say that the spiral doesn't go through this point but beneath it: we must also know limits within which the distance from the point lies. We must know an order of magnitude for the distance apart.

Page 244

Decimal expansion doesn't give me this, since I cannot know, e.g. how many 9s will follow a place that has been reached in the expansion.

Page 244

The question 'Is e $2.7\dot{3}$?' is meaningless, since it doesn't ask about an extension, but about a law, i.e. an induction of which we have, however, no conception here. We can put this question in the case of division only because we know the form of the induction we call $\dot{3}$.

Page 244

The question 'Are the decimal places of e eventually fixed?' and the answer 'They are eventually fixed', are both nonsense. The question runs: After how many stages do the places have to remain fixed?

Page 244

May we say: 'e isn't this number' means nothing--we have to say 'It is at least this interval away from it'?

Page 244

I believe that's how it is. But that implies it couldn't be answered at all unless we were simultaneously given a concept of the distance apart.

Page Break 245

Page 245

From F. Waismann's shorthand notes of a conversation on 30 December 1930

A proof for all real numbers is not analogous to a proof for all rational numbers in such a way that you could say: What we have proved for all rational numbers--i.e. by induction--we can prove for all real numbers in *the same way* by an extension of the method of proof. You can only speak about a real number when you've got it.

Page 245

Let us assume e.g., I have proved the formula $a^m \cdot a^n = a^{m+n}$ for rational values of m and n (by induction), and would now like to prove it for real number values. What do I do in this case? Obviously it's no longer possible to carry through the proof by induction.

Page 245

Therefore such a formula doesn't mean: for all real numbers such and such holds, but: given a real number, I interpret the formula so as to mean: such and such holds for the limit and I prove this by the rules of calculation laid down for the real numbers. I prove the formula for rational numbers by induction, and then show it carries over to the real numbers, in fact simply by means of the rules of calculation I have laid down for the real numbers. But I don't prove the formula holds for 'all real' numbers, precisely because the rules of calculation for real numbers do not have the form of an induction.

Page 245

This, then, is how things are: I treat as given a *particular* real number and keep this constant throughout the proof. That's something totally different from what happens with the rationals; for there it was precisely a question of whether the formula remained correct when the rational numbers were varied, and *that is why* the proof had the form of an induction. But here the question simply doesn't arise whether the formula holds for 'all real' numbers--just because we don't allow the real number to vary at all.

Page 245

We don't let the variable real number run through all values--

Page Break 246

i.e. all laws. We simply rely on the rules of calculation and nothing else.

Page 246

You might now think: strictly the proposition ought to be proved for all real numbers, and what we give is no more than a pointer. That's wrong. A formula that is proved for real numbers doesn't say: For all real numbers... holds; what it says is: Given a real number, then... holds. And in fact not on the basis of a proof, but of an interpretation.

Page Break 247

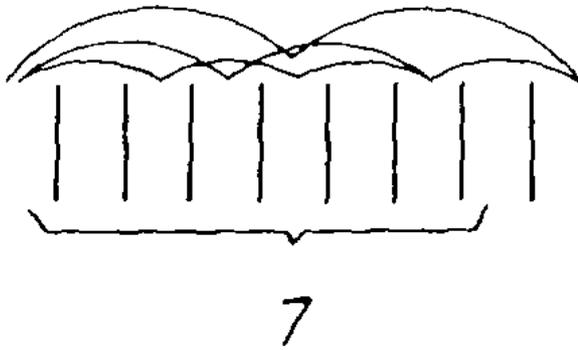

XIX

Page 247

200 Our interest in negation in arithmetic appears to be limited in a peculiar way. In fact it appears to me as if a certain generality is needed to make the negation interesting.

Page 247

But you can represent *indivisibility perspicuously* (e.g. in Eratosthenes' sieve). You can *see* how all the composite numbers lie above or below the number under consideration.

Page 247

Here, arithmetical negation is represented by spatial negation, the 'somewhere else'.

Page 247

What do I *know*, if I know a mathematical inequality? Is it possible to know just an inequality, without knowing something *positive*?

Page 247

It seems clear that negation means something different in arithmetic from what it means in the rest of language. If I say 7 is not divisible by 3, then I can't even make a picture of this, I can't imagine how it would be if 7 were divisible by 3. All this follows naturally from the fact that mathematical equations aren't a kind of proposition.

Page 247

It is very odd that for a presentation of mathematics we should be obliged to use false equations as well. For that is what all this is about. If negation or disjunction is necessary in arithmetic, then false equations are an essential element in its presentation.

Page Break 248

Page 248

What does ' $\sim(5 \times 5 = 30)$ ' mean? It seems to me as if you oughtn't to write it *like that*, but ' $5 \times 5 \neq 30$ '; the reason being that I am not negating anything, but want to establish a relation, even if an indefinite one, between 5×5 and 30 (and so, something positive).--Admittedly you could say: 'True, but this relation is at any rate incompatible with $5 \times 5 = 30$ '.--And so is the relation of indivisibility with the relation of divisibility! It's quite clear that when I exclude divisibility, in this logical system this is equivalent to establishing indivisibility.--And isn't this the same case as that of a number which is less than 5, if it is *not* greater than or equal to it?

Page 248

201 Now, there is something recalcitrant to the application of the law of the excluded middle in mathematics.

Page 248

(Of course even the name of this law is misleading: it always sounds as though this were the same sort of case as 'A frog is either green or brown, there isn't a third type'.)

Page 248

You can show by induction that when you successively subtract 3 from a number until it won't go any further, the remainder can only be either 0 or 1 or 2. You call the cases of the first class those in which the division goes out.

Page 248

Looking for a law for the distribution of primes is simply an attempt to replace the negative criterion for a prime number by a positive one. Or more correctly, the indefinite one by a definite one.

Page 248

I believe that negation here is not what it is in logic but an indefiniteness. For how do I recognize--verify--a negative? By something indefinite or positive.

Page 248

An inequality, like an equation, must be either the result of a calculation or a stipulation.

Page Break 249

Page 249

Just as equations can be construed, not as propositions, but as rules for signs, so it must be possible to treat inequalities in the same way.

Page 249

How, then, can you use an inequality? That leads to the thought that in logic there is also the internal relation of not following, and it can be important to recognize that one proposition does *not* follow from another.

Page 249

The denial of an equation is as like and as unlike the denial of a proposition as the affirmation of an equation is like and unlike the affirmation of a proposition.

Page 249

202 It is quite clear that negation in arithmetic is completely different from the genuine negation of a proposition.

Page 249

And it is of course clear that where it essentially--on logical grounds--corresponds to a disjunction or to the exclusion of one part of a logical series in favour of another, it must have a completely different meaning.

Page 249

It must in fact be one and the same as those logical forms and therefore be only apparently a negation.

Page 249

If 'not equal to' means greater or less than, then that cannot be, as it were, an accident which befalls the 'not'.

Page 249

A mathematical *proposition* can only be either a stipulation, or a result worked out from stipulations in accordance with a definite method. And this must hold for '9 is divisible by 3' or '9 is not divisible by 3'.

Page 249

How do you work out $2 \times 2 \neq 5$? Differently from $2 \times 2 = 4$? If at all, then by $2 \times 2 = 4$ and $4 \neq 5$.

Page 249

And how do you work out '9 is divisible by 3'? You could treat it as a disjunction and first work out $9 \div 3 = 3$, and then, instead of this definite proposition, use a rule of inference to derive the disjunction.

Page Break 250

Page 250

Aren't we helped here by the remark that negation in arithmetic is important only in the context of generality? But the generality is expressed by an induction.

Page 250

And that is what makes it possible for negation or disjunction, which appear as superfluously indefinite in the particular case, yet to be essential to arithmetic in the general 'proposition', i.e. in the induction.

Page 250

203 It is clear to me that arithmetic doesn't need false equations for its construction, but it seems to me that you may well say 'There is a prime number between 11 and 17', without *ipso facto* referring to false equations.

Page 250

Isn't an inequality a perfectly intelligible rule for signs, just as an equation is? The one permits a substitution, the other forbids a substitution.

$$\sqrt{\quad} = 2\sqrt{\quad}, \quad \sqrt{\quad} \neq 3\sqrt{\quad}$$

Page 250

Perhaps all that's essential is that you should see that what is expressed by inequalities is *essentially* different from what is expressed by equations. And so you certainly can't immediately compare a law yielding places of a decimal expansion which works with inequalities, with one that works with equations. Here we have before us completely different methods and consequently different kinds of arithmetical structure.

Page 250

In other words, in arithmetic you cannot just put equations and something else (such as inequalities) on *one* level, as though they were different species of animals. On the contrary, the two methods will be categorically different, and determine (define) structures not comparable with one another.

Page 250

Negation in arithmetic cannot be the same as the negation of a proposition, since otherwise, in $2 \times 2 \neq 5$, I should have to make myself a picture of how it would be for 2×2 to be 5.

Page Break 251

Page 251

204 You could call '= 5', 'divisible by 5', 'not divisible by 5', 'prime', arithmetical predicates and say: arithmetical predicates always correspond to the application of a definite, generally defined, method. You might also define a

predicate in this way: $(\xi \times 3 = 25) \stackrel{\text{Def}}{=} F(\xi)$.

Arithmetical predicates, which in the particular case are unimportant because the definite form makes the indefinite superfluous--become significant in the general *law*, i.e. in induction. Since here they are not--so to speak--superseded by a definite form. Or better: In the general law, they are in no way indefinite.

Could the results of an engineer's computations be such that, let us say, it is essential for certain machine parts to have lengths corresponding to the prime number series? No.

Can you use the prime numbers to construct an irrational number? The answer is always: as far as you can foresee the primes and no further.

If you can foresee that a prime number must occur in *this* interval then this interval is what can be foreseen and constructed, and so, I believe, it can play a role in the construction of an irrational number.

XX

205 Can we say a patch is simpler than a larger one?

Let's suppose they are uniformly coloured circles: what is supposed to constitute the greater simplicity of the smaller circle?

Someone might reply that the larger one can be made up out of the smaller one and a further part, but not vice versa. But why shouldn't I represent the smaller one as the difference between the larger one and the ring?

And so it seems to me that the smaller patch is not simpler than the larger one.

It seems as if it is impossible to see a uniformly coloured patch as composite, unless you imagine it as *not* uniformly coloured. The image of a dissecting line gives the patch more than one colour, since the dissecting line must have a different colour from the rest of the patch.

May we say: If we see a figure in our visual field--a red triangle say--we cannot then describe it by e.g. describing one half of the triangle in one proposition, and the other half in another. That is, we may say that there is a sense in which there is no such thing as a half of *this* triangle. We can only speak of the triangle at all if its boundary lines are the boundaries between two colours.

This is how it is with the composition of spatial structures out of their smaller spatial components: the larger *geometrical* structure isn't composed of smaller *geometrical* structures, any more than you can say that 5 is composed of 3 and 2, or for that matter 2 of 5 and--3. For here the larger determines the smaller quite as much as the

smaller the larger. The rectangle  isn't composed of the rectangles ; instead the first geometrical figure determines the other two and conversely. Here, then, Nicod would be right

when he says [†1] that the larger figure doesn't contain the smaller ones as components. But it is different in actual

space: the figure  is actually composed of the components , even though the purely geometrical figure of the large rectangle is *not* composed of the figures of the two squares.

These 'purely geometrical figures' are of course only logical possibilities.--Now, you can in fact see an actual chess board as a unity not as composed of its squares--by seeing it as a large rectangle and disregarding its squares.--But if you don't disregard the squares, then it is a complex and the squares are its component parts--they are, in Nicod's phrase, what constitute it.

(Incidentally, I am unable to understand what is supposed to be meant by saying that something is 'determined' by certain objects but not 'constituted' by them. If these two expressions make sense at all, it's the same sense.)

Page 253

An intellect which takes in the component parts and their relations, but not the whole, is a nonsense notion.

Page 253

206 Whether it makes sense to say 'This part of a red patch (which isn't demarcated by any visible boundary) is red' depends on whether there is absolute position. For if we can speak of an absolute location in visual space, I can then also ascribe a colour to this absolute location even if its surroundings are the same colour.

Page 253

I see, say, a uniformly yellow visual field and say: 'The centre of my visual field is yellow.' But then can I describe a *shape* in this way?

Page 253

An apparent remedy would appear to be to say that red and circular are (external) properties of two objects, which one might call patches and that in addition these patches are spatially related to each other in a certain way; but this is nonsense.

Page 253

It's obviously possible to establish the identity of a position in the visual field, since we would otherwise be unable to distinguish

Page Break 254

whether a patch always stays in the same place or whether it changes its place. Let's imagine a patch which vanishes and then reappears, we can surely say whether it reappears in the same place or at another.

Page 254

So we can really speak of certain positions in the visual field, and in fact with the same justification as in speaking of different positions on the retina.

Page 254

Would it be appropriate to compare such a space with a surface that has a different curvature at each of its points, so that each point is marked out as distinct?

Page 254

If every point in visual space is marked out as distinct, then there is certainly a sense in speaking of *here* and *there* in visual space, and that now seems to me to simplify the presentation of visual states of affairs. But is this property of having points marked out as distinct really essential to visual space; I mean, couldn't we imagine a visual space in which we would only perceive certain spatial relations but no absolute position? That is, could we picture an experience so? In something like the sense in which we can imagine the experiences of a one-eyed man?--I don't believe we could. For instance, one wouldn't be able to perceive the whole visual field turning, or rather this would be inconceivable. How would the hand of a clock look, say, when it moved around the edge of the dial? (I am imagining the sort of dial you find on many large clocks, that only has points on it, and not digits.) We would then indeed be able to perceive the movement from one point to another--if it didn't just jump from one position to the other--but once the hand had arrived at a point, we wouldn't be able to distinguish its position from the one it was in at the last point. I believe it speaks for itself that we can't visualise this.

Page 254

In visual space there is absolute position and hence also absolute motion. Think of the image of two stars in a pitch-black night, in which I can see nothing but these stars and they orbit around one another.

Page Break 255

Page 255

We can also say visual space is an oriented space, a space in which there is an above and below and a right and left.

Page 255

And *this* above and below, right and left have nothing to do with gravity or right and left hands. It would, e.g., still retain its sense even if we spent our whole lives gazing at the stars through a telescope.

Page 255

Suppose we are looking at the night sky through a telescope, then our visual field would be completely dark with a brighter circle and there would be points of light in this circle. Let us suppose further that we have never seen our bodies, always only this image, so that we couldn't compare the position of a star with that of our head or our

feet. What would then show me that my space has an above and below etc., or simply that it is oriented? I can at any rate perceive that the whole constellation *turns* in the bright circle and that implies I can perceive different orientations of the constellation. If I hold a book the wrong way, I can't read the print at all, or only with difficulty.

Page 255

It's no sort of *explanation* of this situation to say: it's just that the retina has an above and below etc., and this makes it easy to understand that there should exist the analogue in the visual field. Rather, that is just a *representation* of the situation by the roundabout route of the relations on the retina.

Page 255

We might also say, the situation in our visual field is always such as would arise if we could see, along with everything else, a coordinate frame of reference, in accordance with which we can establish any direction.--But even that isn't an accurate representation, since if we really saw such a set of axes of co-ordinates (say, with arrows), we would in fact be in a position, not only to establish the orientations of objects relative to these axes, but also the position of the cross itself in the space, as though in relation to an unseen coordinate system contained in the essence of this space.

Page 255

What would our visual field have to be like, if this were not so? Then of course I could see relative positions and motions, but not

Page Break 256

absolute ones. But that would mean, e.g., that there would be no sense in speaking of a rotation of the whole visual field. Thus far it is perhaps comprehensible. But now let's assume that, say, we saw with our telescope only one star at a certain distance from the black edge: that this star vanishes and reappears at the same distance from the edge. In that case we couldn't know whether it reappears at the same place or in another. Or if two stars were to come and go at the same distance from the edge, we couldn't say whether--or that--they were the same or different stars.

Page 256

Not only: 'we couldn't know whether', but: there would be *no sense* in speaking in this context of the same or different places. And since in reality it has a sense, this isn't the structure of our visual field. The genuine criterion for the structure is precisely which propositions make sense for it--not, which are true. To look for these is the method of philosophy.

Page 256

We might also put it like this: let's suppose that a set of coordinate axes once flared up in our visual field for a few moments and disappeared again, provided our memory were good enough, we could then establish the orientation of every subsequent image by reference to our memory of the axes. If there were no absolute direction, this would be logically impossible.

Page 256

But that means we have the possibility of describing a possible location and so a position--in the visual field, without referring to anything that happens to be there at the time. Thus we can for instance say that something can be at the top on the right, etc.

Page 256

(The analogy with a curved surface would be to say something like: a patch on an egg can be located near the broad end.)

Page 256

I can obviously see the sign V at one time as a v, at another as an A, as a 'greater than' or 'less than' sign, even if I were to see it

Page Break 257

through a telescope and cannot compare its position with the position of my body.

Page 257

Perhaps someone might reply that I feel the position of my body without seeing it. But position in feeling space (as I'd like to put it for once) has nothing to do with position in visual space, the two are independent of each other, and unless there were absolute direction in visual space, you couldn't correlate direction in feeling space with it at all.

Page 257

207 Now, can I say something like: The top half of my visual field is red? And what does that mean? Can I say that an object (the top half) has the property of being red?

Page 257

In this connection, it should be remembered that every part of visual space *must* have a colour, and that

every colour *must* occupy a part of visual space. The forms *colour* and *visual space* permeate one another.

Page 257

It is clear that there isn't a relation of 'being situated' which would hold between a colour and a position, in which it 'was situated'. There is no intermediary between colour and space.

Page 257

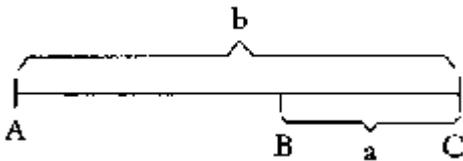

Colour and space saturate one another.

Page 257

And the way in which they permeate one another makes up the visual field.

Page 257

208 It seems to me that the concept of distance is given immediately in the structure of visual space. Were it not so, and the concept of distance only associated with visual space by means of a correlation between a visual space without distance and another structure that contained distance, then the case would be conceivable in which, through an alteration in this association, the length *a*, for example, will appear greater than the length *b*, even though we still observe the point B as always between A and C.

Page Break 258

Page 258

How about when we measure an object in visual space with a yardstick *for a time*? Is it also measured when the yardstick isn't there?

Page 258

Yes, if any sense can be made at all of establishing the identity between what was measured and what is not.

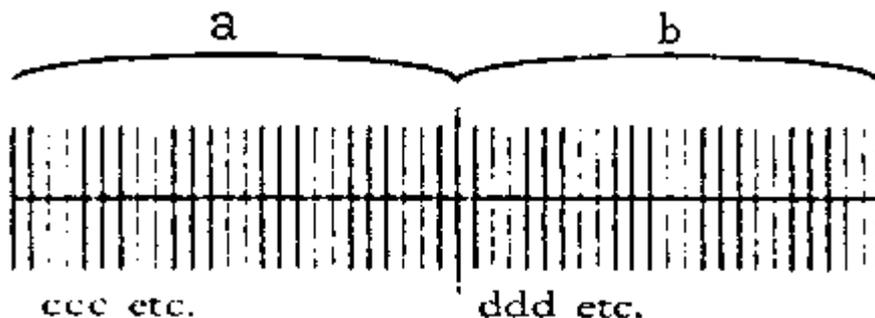

Page 258

If I can say: 'I have measured *this* length and it was three times as long as *that*', then it makes sense and it is correct to say that the lengths are still in the same relationship to one another now.

Page 258

'CC between AA' follows from 'CC between BB', but only if the partition is really given, through colour boundaries.

Page 258

It is obviously possible for the intervals *a* and *b* to appear to me to be the same in length and for the segments *c* and the segments *d* also to appear to me to be the same in length but for there still to be 25 *cs* and 24 *ds* when I count them. And the question arises: how can that be possible? Is it correct to say here: but it is so, and all we see is that visual space does not obey the rules of--say--Euclidean space? This would imply that the question 'How can that be possible?' was nonsense and so unjustified. And so there wouldn't be anything paradoxical in this at all, we would simply have to accept it. But is it *conceivable* that *a* should appear equal to *b* and the *cs* to the *ds*, and a *visibly* different number of *cs* and *ds* be present?

Page 258

Or should I now say that even in visual space something can after all *appear* different from what it *is*? Certainly not! Or that n times an interval and $n + 1$ times the same interval can yield

Page Break 259

precisely the same result in visual space? That is just as unacceptable. Except if there is no sense at all in saying of intervals in visual space that they *are* equal. If, that is, in visual space it only made sense to talk of a 'seeming' and this expression weren't only appropriate for the relationship between two independent experiences. And so if there were an *absolute* seeming.

Page 259

And so perhaps also an *absolute* vagueness or an *absolute* unclarity. (Whereas on my view, something can only be vague or unclear with reference to something we have posited as the standard of clarity: therefore relatively.)

Page 259

Can't I then--in the first case--if I can't take in the number at a glance, make a mistake in determining this number? Or: are a and b composed of a number of parts at all--in the ordinary sense--if I can't *see* this number in a and b ? For it certainly seems I've no right at all to *conclude* that the same number of c s and of d s must be present. And this still holds, even if counting really does yield the same number! I mean: even if counting were never to yield different results where a and b are equal etc.

Page 259

(This shows, incidentally, how difficult it is to describe what it is that we really see.)

Page 259

But suppose we have the right to talk of a number of parts--N.B. remaining throughout at the purely visual level--even when we don't see the number immediately; then the question would arise: can I in that case be sure that what I count is really the number I see or rather whose visual result I see? Could I be sure that the number of parts doesn't instantaneously change from 24 to 25 without my noticing it?

Page 259

If I see $a = b$ and $c = d$ and someone else counts the parts and finds the numbers equal, I shall at least feel that that doesn't contradict what I see. But I am also aware that I can see the same when there are 25 c s in a and 24 d s in b . From this I can conclude that I don't notice when there's one part more or one less, and

Page Break 260

therefore also cannot notice if the number of parts in b changes between 24 and 25.

Page 260

209 But if you can't say that there is a definite number of parts in a and b , how am I in that case to describe the visual image? Here it emerges--I believe--that the visual image is much more complicated than it seems to be at first glance. What makes it so much more complicated is e.g. the factor introduced by eye movements.

Page 260

If--say--I were to describe what is seen at a glance by painting a picture instead of using the language of words, then I ought not really to paint all the parts c and d . In many places I should have to paint something 'blurred' instead, i.e. a grey section.

Page 260

'Blurred' [†1] and 'unclear' are relative expressions. If this often doesn't seem to be so, that results from the fact that we still know too little of the real nature of the given phenomena, that we imagine them as more primitive than they are. Thus it is, e.g., possible that no coloured picture of any kind whatever is able to represent the impression of 'blurredness' correctly. But it doesn't follow from that that the visual image is blurred in itself and so can't be represented by any kind of definite picture whatever. No, this would only indicate that a factor plays a part in the visual image--say through eye movements--which admittedly can't be reproduced by a painted picture, but which is in itself as 'definite' as any other. You might in that case say, what is really given is still always indefinite or blurred relative to the painted picture, but merely because we have in that case made the painted picture arbitrarily into a standard for the given, when this has a greater multiplicity than that of a painted representation.

Page 260

It[[sic]] we were really to *see* 24 and 25 parts in a and b , we couldn't then see a and b as equal.

Page 260

If this is wrong, the following must be possible: it ought to be possible to distinguish immediately between the cases where a

Page Break 261

and b both equal 24 and the case where a is 24 and b 25, but it would only be possible to distinguish between the number of parts, and not between the lengths of a and b that result.

Page 261

We might also put this more simply thus: it would then have to be possible to see immediately that one interval is made up of 24 parts, the other of 25, without it being possible to distinguish the resulting lengths.--I believe that the word 'equal' has a meaning even for visual space which stamps this as a contradiction.

Page 261

Do I tell that two intervals of visual space are equal by not telling that they are unequal? This is a question with far-reaching implications.

Page 261

Couldn't I have two impressions in succession: in one, an interval visibly divided into 5 parts, in the other one visibly divided in the same way into 6 parts, while I yet couldn't say that I had seen the parts or the entire intervals as having different lengths?

Page 261

Asked 'Were the intervals different in length or the same?' I couldn't answer 'I saw them as different in length', since no difference in length has so to speak 'struck' me. And yet I couldn't --I believe--say that I saw them as equal in length. On the other hand, I couldn't say either: 'I don't know whether they were the same or different in length' (unless my memory had deserted me), for that means nothing so long as I go on talking only of the immediately given.

Page 261

210 The question is, how to explain certain contradictions that arise when we apply the methods of inference used in Euclidean space to visual space.

Page 261

I mean: it is possible to carry through a construction (i.e. a chain of inference) in visual space in which we appreciate every step (transition), but whose result contradicts our geometrical concepts.

Page Break 262

Page 262

Now I believe this happens because we can only see the construction piecemeal and not as one whole. The explanation would then consist in saying that there isn't a visual construction at all that is composed of these individual visual pieces. This would be something like what happens when I show someone a small section of a large spherical surface and ask him whether he accepts the great circle which is visible on it as a straight line; and if he did so, I would then rotate the sphere and show him that it came back to the same place on the circle. But I surely haven't proved to him in this way that a straight line in visual space returns to meet itself.

Page 262

This explanation would be: these are visual *pieces* which do not, however, add up to a visual whole, or at any rate not to the whole the final result of which I believe I can see at the end.

Page 262

The simplest construction of this sort would, indeed, be the one above of the two equally long intervals into one of which a piece will go n times and into the other $n + 1$ times. The steps of the construction would lie in proceeding from one component part to another and discovering the equality of these parts.

Page 262

Here you could explain that, in making this progression, I am not really investigating the original visual image of the equally long intervals. But that something else obtrudes into the investigation, which then leads to the startling result.

Page 262

But there's an objection to this explanation. Someone might say: we didn't hide any part of the construction from you while you were examining the individual parts, did we? So you ought to have been able to see whether anything about the rest changed, shifted in the meantime. If that didn't happen, then you really ought to be able to see, oughtn't you, that everything was above board?

Page 262

To speak of divisibility in visual space has a sense, since in a description it must be possible to substitute a divided stretch for

Page Break 263

an undivided one. And then it is clear what, in the light of what I elaborated earlier, the infinite divisibility of this space means.

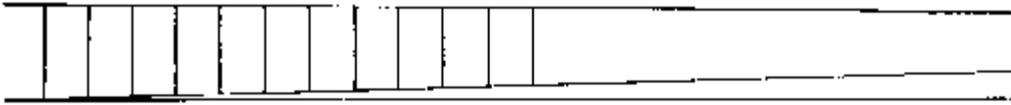

211 The moment we try to apply exact concepts of measurement to immediate experience, we come up against a peculiar vagueness in this experience. But that only means a vagueness relative to these concepts of measurement. And, now, it seems to me that this vagueness isn't something provisional, to be eliminated later on by more precise knowledge, but that this is a characteristic logical peculiarity. If, e.g., I say: 'I can now see a red circle on a blue ground and remember seeing one a few minutes ago that was the same size or perhaps a little smaller and a little lighter,' then *this* experience cannot be described more precisely.

Admittedly the words 'rough', 'approximate' etc. have only a relative sense, but they are still *needed* and they characterise the nature of our experience; not as rough or vague in itself, but still as rough and vague in relation to our techniques of representation.

This is all connected with the problem 'How many grains of sand make a heap?'

You might say: any group with more than a hundred grains is a heap and less than ten grains do not make a heap: but this has to be taken in such a way that ten and a hundred are not regarded as limits which could be essential to the concept 'heap'.

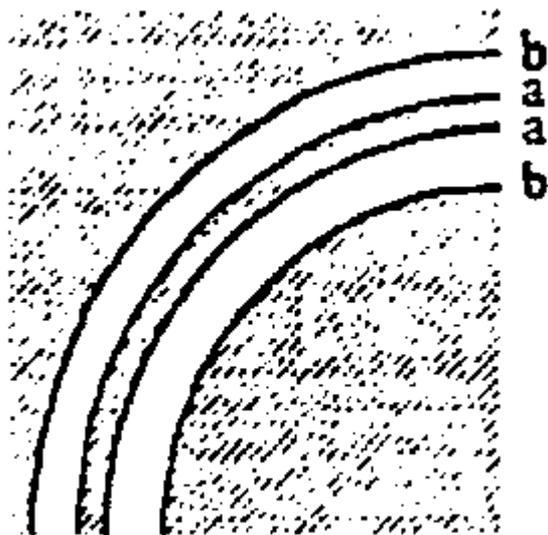

And this is the same problem as the one specifying which of the vertical strokes we first notice to have a different length from the first.

What corresponds in Euclidean geometry to the visual circle isn't a circle, but a class of figures, including the circle, but also, e.g., the hundred-sided regular polygon. The defining characteristic of this class could be something like their all being figures

contained in a band which arises through the vibration of a circle.--But even that is wrong: for why should I take precisely the band which arises from vibrating a circle and not that produced by vibrating the hundred-sided polygon?

And here I come up against the cardinal difficulty, since it seems as though an exact *demarcation* of the inexactitude is impossible. For the demarcation is arbitrary, since how is what corresponds to the vibrating circle distinguished from what corresponds to the vibrating hundred-sided polygon?

There is something attractive about the following explanation: everything that is within a appears as the visual circle C , everything that is outside b does not appear as C . We would then have the case of the word 'heap'. There would be an indeterminate zone left open, and the boundaries a and b are not essential to the concept defined.--The boundaries a and b are still only like the walls of the *forecourts*. They are drawn arbitrarily at a point where we can still draw something firm.--Just as if we were to border off a swamp with a wall, where the wall is not *the* boundary of the swamp, it only stands around it on firm ground. It is a sign which shows there is a swamp inside it, but not, that the swamp is exactly the same size as that of the surface bounded by it.

Page Break 265

Page 265

212 Now isn't the correlation between visual space and Euclidean space as follows: no matter what Euclidean figure I show to the observer, he must be able to distinguish whether or not it is the visual circle C . That is to say, by constantly reducing the interval between the figures shown I shall be able to reduce the indeterminate interval indefinitely, be able 'to approach indefinitely close to a limit between what I see as C and what I see as not C '.

Page 265

But on the other hand, I shall never be able to draw such a limit as a curve in Euclidean space, for if I could, it would itself then have to belong to one of the two classes and be the last member of this class, in which case I would have to be able to see a Euclidean curve after all.

Page 265

If someone says e.g. that we never see a real circle but always only approximations to one, this has a sound, unobjectionable sense, if it means that, given a body which looks circular, we can still always discover inaccuracies by precise measurement or by looking through a magnifying glass. But we lose this sense the moment we substitute the immediately given, the patch or whatever we choose to call it, for the circular body.

Page 265

If a circle is at all the sort of thing that we see--see in the same sense as that in which we see a blue patch--then we must be able to see it and not merely something like it.

Page 265

If I cannot see an exact circle then in this sense neither can I see approximations to one.--But then the Euclidean circle--and the Euclidean approximation to one--is in this sense not an object of my perception at all, but, say, only a different logical construction which could be obtained from the objects of a quite different space from the space of immediate vision.

Page 265

But even this way of talking is misleading, and we must rather say that we see the Euclidean circle in a different sense.

Page 265

And so that a different sort of projection exists between the

Page Break 266

Euclidean circle and the circle perceived than one would naïvely suppose.

Page 266

If I say you can't distinguish between a chiliagon and a circle, then the chiliagon must here be given through its construction, its origin. For how else would I know that it is 'in fact' a chiliagon and *not* a circle?

Page 266

In visual space there is no measurement.

Page 266

We could, e.g., perfectly well give the following definitions for visual space: 'A straight line is one that isn't curved' and 'A circle is a curve with constant curvature'.

Page 266

213 We need new concepts and we continually resort to those of the language of physical objects. The word 'precision' is one of these dubious expressions. In ordinary language it refers to a *comparison* and then it is quite intelligible. Where a certain degree of imprecision is present, perfect precision is also possible. But what is it supposed to mean when I say I can never see a precise circle, and am now using this word not relatively, but absolutely?

Page 266

The words 'I see' in 'I see a patch' and 'I see a line' therefore have different meanings.

Page 266

Suppose I have to say 'I never see a perfectly sharp line'. I have then to ask 'Is a sharp line conceivable?' If it

is right to say 'I do not see a sharp line', than a sharp line *is* conceivable. If it makes sense to say 'I never see an exact circle', then this implies: an exact circle is conceivable in visual space.

Page 266

If an exact circle in a visual field is inconceivable, the proposition 'I never see an exact circle in my visual field' must be the same sort of proposition as 'I never see a high C in my visual field'.

Page 266

If I say 'The upper interval is as long as the lower' and mean by this what is usually said by the proposition 'the upper interval

Page Break 267

appears to me as long as the lower', then the word 'equal' [†1] means something quite different in this proposition from what it means in the proposition expressed in the same words but which is verified by comparing lengths with dividers. For this reason I can, e.g., speak in the latter case of improving the techniques of comparison, but not in the former. The use of the same word 'equal' with quite different meanings is very confusing. This is the typical case of words and phrases which originally referred to the 'things' of the idioms for talking about physical objects, the 'bodies in space', being applied to the elements of our visual field; in the course of this they inevitably change their meanings utterly and statements which previously had had a sense now lose it and others which had had no sense in the first way of speaking now acquire one. Even though a certain analogy does persist--just the one which tricks us into using the same expression.

Page 267

It is, e.g., important that the word 'close' means something different in the proposition 'There is a red patch close to the boundary of the visual field' and in such a proposition as 'The red patch in the visual field is close to the brown one'. Furthermore the word 'boundary' in the first proposition also has a different meaning--and is a different sort of word from 'boundary' in the proposition: 'the boundary between red and blue in the visual field is a circle'.

Page 267

What sense does it make to say: our visual field is less clear at the edges than towards the middle? That is, if we aren't here talking about the fact that we see physical objects more clearly in the middle of the visual field?

Page 267

One of the clearest examples of the confusion between physical and phenomenological language is the picture Mach [†2] made of his visual field, in which the so-called blurredness of the figures near the edge of the visual field was reproduced by a blurredness (in a quite different sense) in the drawing. No, you can't make a visual picture of our visual image.

Page Break 268

Page 268

Can I therefore say that colour patches near the edge of the visual field no longer have sharp contours: are contours then *conceivable* there? I believe it is clear that this lack of clarity is an internal property of visual space. Has, e.g., the word 'colour' a different meaning when it refers to figures near to the edge?

Page 268

Without this 'blurredness' the limitlessness of visual space isn't conceivable.

Page 268

214 The question arises what distinctions are there in visual space. Can we learn anything about this from the co-ordination, e.g., of tactile space with visual space? Say, by specifying which changes in one space do not correspond to a change in the other?

Page 268

The fact that you see a physical hundred-sided polygon as a circle--cannot distinguish it from a physical circle--implies nothing here as to the *possibility* of seeing a hundred-sided polygon.

Page 268

That it proves impossible for me to find physical bodies which give the visual image of a hundred-sided visual polygon is of no significance for logic. The question is: is there a *sense* in speaking of a hundred-sided polygon? Or: Does it make sense to talk of thirty strokes in a row *taken in at one look*? I believe there is none.

Page 268

The process isn't at all one of seeing first a triangle, then a square, pentagon etc. up to e.g. a fifty-sided polygon and then the circle coming; no[[sic]] we see a triangle, a square etc., up to, maybe, an octagon, then we see only polygons with sides of varying length. The sides get shorter, then a fluctuation towards the circle begins, and then comes the circle.

Neither does the fact that a physical straight line drawn as a tangent to a circle gives the visual image of a straight line which for a stretch merges with the curve prove that our visual space isn't Euclidean, for a different physical configuration could perfectly well produce the image corresponding to the Euclidean tangent. But in fact such an image is inconceivable.

215 What is meant by the proposition 'We never see a precise circle'? What is the criterion of precision? Couldn't I also perfectly well say: 'Perhaps I see a precise circle, but can never know it'? All this only makes sense, once it has been established in what cases one calls one measurement more precise than another. Now the concept of a circle presupposes--I believe--a concept of 'greater precision', which contains an infinite possibility of being increased. And we may say the concept of a circle *is* the concept of the infinite possibility of greater precision. This infinite possibility of increase would be a postulate of this idiom. Of course, it must then be clear in every case what I would regard as an increase in precision.

It obviously means nothing to say the circle is only an ideal to which reality can only approximate. This is a misleading metaphor. For you can only approximate to something that is there, and if the circle is given us in any form that makes it possible for us to approximate, then precisely that form would be the important thing for us, and approximation to another form in itself of secondary importance. But it may also be that we call an infinite possibility itself, a circle. So that the circle would then be in the same position as an irrational number.

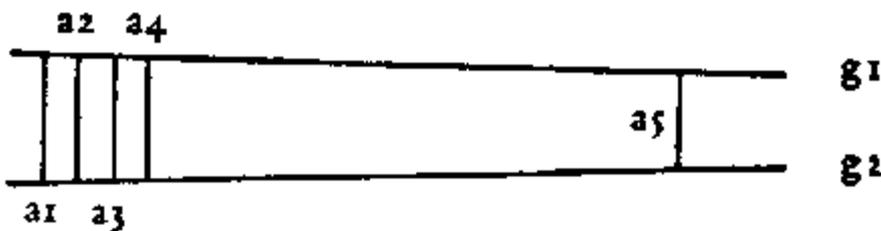

It seems essential to the application of Euclidean geometry that we talk of an *imprecise* circle, an imprecise *sphere* etc. And also that this imprecision must be logically susceptible of an unlimited reduction. And so, if someone is to understand the application of Euclidean geometry, he has to know what the word '*imprecise*' means. For nothing is given us over and above the result of our measuring and the concept of imprecision. These two together must correspond to Euclidean geometry.

Now, is the imprecision of measurement the same concept as the imprecision of visual images? I believe: Certainly not.

If the assertion that we never *see* a precise circle is supposed to mean, e.g., that we never see a straight line touch a circle at one point (i.e. that nothing in our visual space has the multiplicity of a

line touching a circle), then for *this* imprecision, an indefinitely high degree of precision is not conceivable.

The word 'equality' has a different meaning when applied to intervals in visual space and when applied in physical space. Equality in visual space has a different multiplicity from equality in physical space, so that in visual space g_1 and g_2 can be straight

lines (visually straight) and the lengths $a_1 = a_2$, $a_2 = a_3$ etc., but *not* $a_1 = a_5$. Equally, a circle and a straight line in visual space have a different multiplicity from a circle and a straight line in physical space, for a short stretch of a seen circle can be straight; 'circle' and 'straight line' simply used in the sense of visual geometry.

Here ordinary language resorts to the words 'seems' or 'appears'. It says a_1 seems to be equal to a_2 , whereas this appearance has ceased to exist in the case of a_1 and a_5 . But it uses the word 'seems' ambiguously. For its meaning depends on what is opposed to this appearance as reality. In one case it is the result of measurement, in another a further appearance. And so the meaning of the word 'seem' is different in these two cases.

216 The time has now come to subject the phrase 'sense-datum' to criticism. A sense-datum is the appearance of this

tree, whether 'there really is a tree standing there' or a dummy, a mirror image, an hallucination, etc. A sense-datum is the appearance of the tree, and what we want to say is that its representation in language is only *one* description, but not *the* essential one. Just as you can say of the expression '*my* visual image' that it is only one form of description, but by no means the only possible and correct one. For the form of words 'the appearance of this tree' incorporates

Page Break 271

the idea of a necessary connection between what we are calling the appearance and 'the existence of a tree', in fact whether it be veridical perception or a mistake. That is to say, if we talk about 'the appearance of a tree', we are either taking for a tree something which is one, or something which is not one. But this connection isn't there.

Page 271

Idealists would like to reproach language with presenting what is secondary as primary and what is primary as secondary. But that is only the case with these inessential valuations which are independent of cognition ('only' an appearance). Apart from that, ordinary language makes no decision as to what is primary or secondary. We have no reason to accept that the expression 'the appearance of a tree' represents something which is secondary in relation to the expression 'tree'. The expression 'only an image' goes back to the idea that we can't eat the image of an apple.

Page 271

217 We might think that the right model for visual space would be a Euclidean drawing-board with its ideally fine constructions which we make vibrate so that all the constructions are to a certain extent blurred (further, the surface vibrates equally in all the directions lying in it). We could in fact say: it is to be vibrated precisely as far as it can without its yet being noticeable, and then its physical geometry will be a picture of our phenomenological geometry.

Page 271

But the big question is: Can you translate the 'blurredness' of phenomena into an imprecision in the drawing? It seems to me that you can't.

Page 271

It is, for instance, impossible to represent the imprecision of what is immediately seen by thick strokes and dots in the drawing.

Page 271

Just as we cannot represent the memory of a picture by this picture painted in faint colours. The faintness of memory is something quite other than the faintness of a hue we see; and the unclarity of vision different *in kind* from the blurredness of an

Page Break 272

imprecise drawing. (Indeed, an imprecise drawing is seen with precisely the unclarity we are trying to represent by its imprecision.)

Page 272

(In films, when a memory or dream is to be represented, the pictures are given a bluish tint. But memory images have no bluish tint, and so the bluish projections are not visually accurate pictures of the dream, but pictures in a sense which is not immediately visual.)

Page 272

A line in the visual field need not be either straight or curved. Of course the third possibility should not be called 'doubtful' (that is nonsense); we ought to use another word for it, or rather replace the whole way of speaking by a different one.

Page 272

That visual space isn't Euclidean is already shown by the occurrence of two different kinds of lines and points: we see the fixed stars as points: that is, we can't see the contours of a fixed star, and in a different sense two colour boundaries also intersect in a point; similarly for lines. I can see a luminous line without thickness, since otherwise I should be able to see a cross-section of it as a rectangle or at least the four points of intersection of its contours.

Page 272

A visual circle and a visual straight line can have a stretch in common.

Page 272

If I look at a drawn circle with a tangent, it wouldn't be remarkable that I never see a perfect circle and a perfect straight line touch one another, it only becomes interesting when I see this happen, and the straight line and the circle then coincide for a stretch.

Page 272

For only that would imply that the visual circle and the visual line are essentially different from the circle and

line of Euclidean geometry; but the first case, that we have never seen a perfect circle and a perfect line touch one another, would not.

Page Break 273

XXI

Page 273

218 There appear to be simple colours. Simple as psychological phenomena. What I need is a psychological or rather phenomenological colour theory, not a physical and equally not a physiological one.

Page 273

Furthermore, it must be a theory in *pure* phenomenology in which mention is only made of what is actually perceptible and in which no hypothetical objects--waves, rods, cones and all that--occur.

Page 273

Now, we can recognize colours as mixtures of red, green, blue, yellow, white and black *immediately*. Where this is still always the colour itself, and not pigment, light, process on or in the retina, etc.

Page 273

We can also see that one colour is redder than another or whiter, etc. But can I find a metric for colours? Is there a sense in saying, for instance, that with respect to the amount of red in it one colour is *halfway* between two other colours?

Page 273

At least there seems to be a sense in saying that one colour is closer in this respect to a second than it is to a third.

Page 273

219 You might say, violet and orange partially obliterate one another when mixed, but not red and yellow.

Page 273

At any rate orange is a mixture of red and yellow in a sense in which yellow isn't a mixture of red and green, although yellow comes between red and green in the colour circle.

Page 273

And if that happens to be manifest nonsense, the question arises, at what point does it begin to make sense; that is, if I now move on the circle from red and from green towards yellow and call yellow a mixture of the two colours I have now reached.

Page 273

That is, in yellow I recognize an affinity with red and with green, viz. the possibility of reddish yellow--and yet I still don't

Page Break 274

recognize green and red as component parts of yellow in the sense in which I recognize red and yellow as component parts of orange.

Page 274

I want to say that red is between violet and orange only in the sense in which white is between pink and greenish-white. But, in this sense, isn't any colour between any two other colours, or at least between any two which may be reached from the first by independent routes?

Page 274

Can one say that in this sense a colour only lies between two others with reference to a specified continuous transition? And so, say, blue between red and black?

Page 274

Is this then how it is: to say the colour of a patch is a mixture of orange and violet is to ascribe to it a different colour from that ascribed by saying that the patch has the colour common to violet and orange?--But that won't work either; for, in the sense in which orange is a mixture of red and yellow, there isn't a mixture of orange and violet at all. If I imagine mixing a blue-green with a yellow-green, I see straightaway that it can't happen, that, on the contrary, a component part would first have to be 'killed' before the union could occur. This isn't the case with red and yellow. And in this I don't have an image of a continuous transition (via green), only the discrete hues play a part here.

Page 274

220 I must know what in general is meant by the expression 'mixture of colours A and B', since its application isn't limited to a finite number of pairs. Thus if, e.g., someone shows me any shade of orange and a white and says the colour of a patch is a mixture of these two, then I must understand this, and I can understand it.

Page 274

If someone says to me that the colour of a patch lies between violet and red, I understand this and can imagine a redder violet than the one given. If, now, someone says to me the colour lies between this violet and an orange--where I don't have a specific continuous transition before me in the shape of a painted colour circle--then I can at best think that here, too, a redder violet is meant, but a redder orange might also be what is meant, since,

Page Break 275

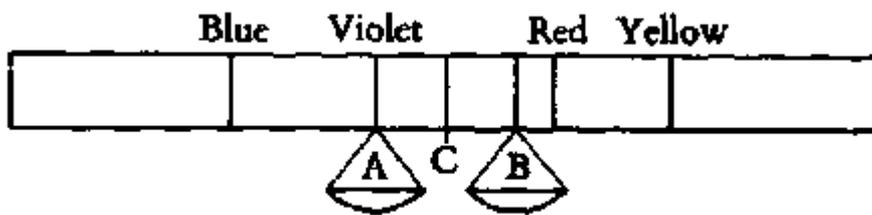

leaving on one side a given colour circle, there is no colour lying *halfway* between the two colours, and for just this reason neither can I say at what point the orange forming one limit is already too close to the yellow for it still to be mixed with the violet; the point is that I can't tell which orange lies at a distance of 90° from violet on the colour circle. The way in which the mixed colour lies between the others is no different here from the way red comes between blue and yellow.

Page 275

If I say in the ordinary sense that red and yellow make orange, I am not talking here about a *quantity* of the components. And so, given an orange, I can't say that yet *more* red would have made it a redder orange (I'm not of course speaking about pigments), even though there is of course a sense in speaking of a redder orange. But there is, e.g., no sense in saying this orange and this violet contain the same amount of red. And how much red would *red* contain?

Page 275

The comparison we are seduced into making is one between the colour series and a system of two weights on the beam of a balance, where I can move the centre of gravity of the system just as I choose, by increasing or moving the weights.

Page 275

Now it's nonsense to believe that if I held the scale A at violet and moved the scale B into the red-yellow region, C will then move towards red.

Page 275

And what about the weights I put on the scales: Does it mean anything to say, '*more of this* red'? when I'm not talking about pigments. That can only mean something if I understand by pure red a number of units, where the number is stipulated at the outset. But then the complete number of units means nothing but that the

Page Break 276

scale is standing at red. And so the relative numbers again only specify a point on the balance, and not a point and a weight.

Page 276

Now so long as I keep my two end colours in say, the blue-red region, and move the redder colour, I can say that the resultant also moves towards red. But if I move one end-colour beyond red, and move it towards yellow, the resultant doesn't now become redder! Mixing a yellowish red with a violet doesn't make the violet redder than mixing pure red with the violet. That the one red has now become yellower even takes away something of the red and doesn't add red.

Page 276

We could also describe this as follows: if I have a paint pot of violet pigment and another of orange, and now increase the amount of orange added to the mixture, the colour of the mixture will gradually move away from violet towards orange, but not via pure red.

Page 276

I can say of two different shades of orange that I have no grounds for saying of either that it is closer to red than yellow.--There simply isn't a 'midpoint' here.--On the other hand, I can't see two different reds and be in doubt whether one of them, and if so which, is pure red. That is because pure red is a point, but the midway between red and yellow isn't.

Page 276

221 Admittedly it's true that we can say of an orange that it's almost yellow, and so that it is 'closer to yellow than to

red' and analogously for an almost red orange. But it doesn't follow from this that there must also be a midpoint between red and yellow. Here the position is just as it is with the geometry of visual space as compared with Euclidean geometry. There are here quantities of a different sort from that represented by our rational numbers. The concepts 'closer to' and 'further from' are simply of no use at all or are misleading when we apply these phrases.

Page Break 277

Page 277

Or again: to say of a colour that it lies between red and blue doesn't define it sharply (unambiguously). But the pure colours must be defined *unambiguously* when it is stated that they lie between certain mixed colours. And so the phrase 'lie between' means something *different* from what it meant in the first case. That is to say, if the expression 'lie between' on one occasion designates a mixture of two simple colours, and on another a simple component common to two mixed colours, the multiplicity of its application is different in the two cases. And this is *not* a difference in degree, it's an expression of the fact that we are dealing with two entirely different categories.

Page 277

We say a colour can't be between green-yellow and blue-red in the same sense as between red and yellow, but we can only say this because in the latter case we can distinguish the angle of 90° ; because we see yellow and red as *points*. But there simply is no such distinguishing in the other case where the mixed colours are regarded as primary. And so in this case we can, so to speak, never be certain whether the mixture is still possible or not. To be sure, I could choose mixed colours at random and stipulate that they include an angle of 90° ; but this would be completely arbitrary, whereas it isn't arbitrary when we say that in the first sense there is no mixture of blue-red and green-yellow.

Page 277

So in the one case grammar yields the 'angle of 90° ', and now we are misled into thinking: we only need to bisect it and the adjacent segment too, to arrive at another 90° segment. But here the *metaphor* of an angle collapses.

Page 277

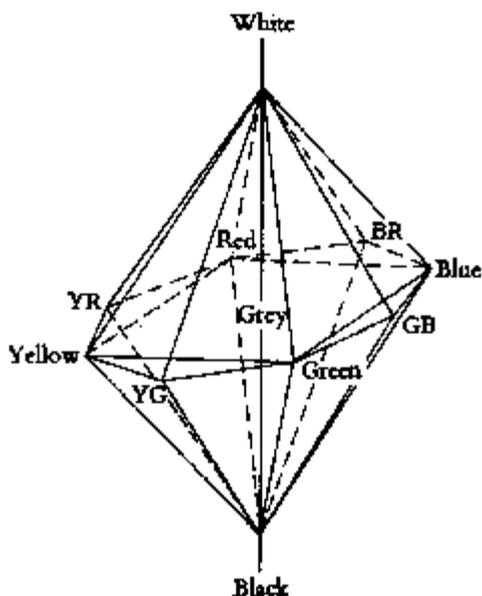

Of course you can also arrange all the shades in a straight line, say with black and white as endpoints, as has been done, but then you have to introduce rules to exclude certain transitions, and in the end the representation on the line must be given the same kind of topological structure as the octahedron has. In this, it's completely analogous to the relation of ordinary language to a 'logically purified' mode of expression. The two are completely equivalent;

Page Break 278

it's just that one of them already wears the rules of grammar on its face.

Page 278

To what extent can you say that grey is a mixture of black and white *in the same sense* as orange is a mixture of red and yellow? And doesn't lie between black and white in the sense in which red lies between blue-red and orange?

Page 278

If we represent the colours by means of a double-cone, instead of an octahedron, there is only one *between* on the colour circle, and red appears on it between blue-red and orange in the same sense as that in which blue-red lies between blue and red. And if in fact that is all there is to be said, then a representation by means of a

double-cone is adequate, or at least one using a double eight-sided pyramid is.

Page 278

222 Now strangely enough, it seems clear from the outset that we can't say red has an orange tinge in the same sense as orange

Page Break 279

has a reddish tinge. That is to say, it seems to be clear that the phrases 'x is composed of (is a mixture of) y and z' and 'x is the common component of y and z' are not interchangeable here: Were they so, the relation *between* would be all we needed for a representation.

Page 279

In general, the phrases 'common component of' and 'mixture of' have different meanings only if one can be used in a context where the other can't.

Page 279

Now, it's irrelevant to our investigation that when I mix blue and green pigments I get a blue-green, but when I mix blue-green and blue-red the result isn't a blue.

Page 279

If I am right in my way of thinking, then 'Red is a pure colour' isn't a proposition, and what it is meant to show is not susceptible to experimental testing. So that it is inconceivable that at one time red and at another blue-red should appear to us to be pure.

Page 279

223 Besides the transition from colour to colour on the colour-circle, there seems to be another specific transition that we have before us when we see dots of one colour intermingled with dots of another. Of course I mean here a *seen* transition.

Page 279

And this sort of transition gives a new meaning to the word 'mixture', which doesn't coincide with the relation 'between' on the colour-circle.

Page 279

You might describe it like this: I can imagine an orange-coloured patch as having arisen from intermingling red and yellow dots, whereas I can't imagine a red patch as having arisen from intermingling violet and orange dots.--In this sense, grey is a mixture of black and white, but white isn't a mixture of pink and a whitish green.

Page 279

But I don't mean that it is established by experimental mixing that certain colours arise in this way from others. I could, say,

Page Break 280

perform the experiment with a rotating coloured disc. Then it might work or might not, but that will only show whether or not the visual process in question can be produced by these physical means--it doesn't show whether the process is possible. Just as physical dissection of a surface can neither prove nor refute visual divisibility. For suppose I can no longer see a physical dissection as a visual dissection, but when drunk see the undivided surface as divided, then wasn't the visual surface divisible?

Page 280

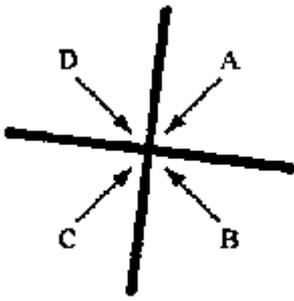

If I am given two shades of red, say, which are close to one another, it's impossible to be in doubt whether both lie between red and blue, or both between red and yellow, or one between red and blue and the other between red and yellow. And in deciding this, we have also decided whether both will mix with blue or with yellow, or one with blue and one with yellow, and this holds no matter how close the shades are brought together so long as we are still capable of distinguishing the pigments by colour at all.

Page 280

If we ask whether the musical scale carries with it an infinite possibility of being continued, then it's no answer to say that we can no longer perceive vibrations of the air that exceed a certain rate of vibration as notes, since it might be possible to bring about sensations of higher notes in another way. Rather, the finitude of the musical scale can only derive from its internal properties. For instance, from our being able to tell from a note *itself* that it is the final one, and so that this last note, or the last notes, exhibit inner properties which the notes in between don't have.

Page 280

Just as thin lines in our visual field exhibit internal properties not possessed by the thicker ones, so that there is a line in our visual field, which isn't a colour boundary but is itself coloured, and yet in a specific sense has no breadth, so that when it intersects another such line we do not see four points A, B, C, D.

224 Nowadays the danger that lies in trying to see things as simpler than they really are is often greatly exaggerated. But this danger does actually exist to the highest degree in the phenomenological investigation of sense impressions. These are always taken to be *much* simpler than they are.

If I see that a figure possesses an organization which previously I hadn't noticed, I now see a different figure. Thus I can see ||||| as a special case of || || || or of ||| ||| or of | |||| | etc. This merely shows that that which we see isn't as simple as it appears.

Understanding a Gregorian mode doesn't mean getting used to the sequence of notes in the sense in which I can get used to a smell and after a while cease to find it unpleasant. No, it means hearing something new, which I haven't heard before, much in the same way--in fact it's a complete analogy--as it would be if I were suddenly able to see 10 strokes |||||, which I had hitherto only been able to see as twice five strokes, as a characteristic whole. Or suddenly seeing the picture of a cube as 3-dimensional when I had previously only been able to see it as a flat pattern.

The limitlessness of visual space stands out most clearly, when we can see nothing, in pitch-darkness.

XXII

225 A proposition, an hypothesis, is coupled with reality--with varying degrees of freedom. In the limit case there's no longer any connection, reality can do anything it likes without coming into conflict with the proposition: in which case the proposition (hypothesis) is senseless!

All that matters is that the signs, in no matter how complicated a way, still in the end refer to immediate experience and not to an intermediary (a thing in itself).

All that's required for our propositions (about reality) to have a sense, is that our experience *in some sense or other* either tends to agree with them or tends not to agree with them. That is, immediate experience need confirm only something about them, *some* facet of them. And in fact this image is taken straight from reality, since we say 'There's a chair here', when we only see *one* side of it.

According to my principle, two assumptions must be identical in sense if every possible experience that confirms the one confirms the other too. Thus, if no empirical way of deciding between them is conceivable.

A proposition construed in such a way that it can be uncheckably true or false is completely detached from reality and no longer functions as a proposition.

The views of modern physicists (Eddington) tally with mine completely, when they say that the signs in their equations no longer have 'meanings', and that physics cannot attain to such meanings but must stay put at the signs. But they don't see that these signs have meaning in as much as--and only in as much

as--immediately observable phenomena (such as points of light) do or do not correspond to them.

A phenomenon isn't a symptom of something else: it is the reality.

Page 283

A phenomenon isn't a symptom of something else which alone makes the proposition true or false: it itself is what verifies the proposition.

Page 283

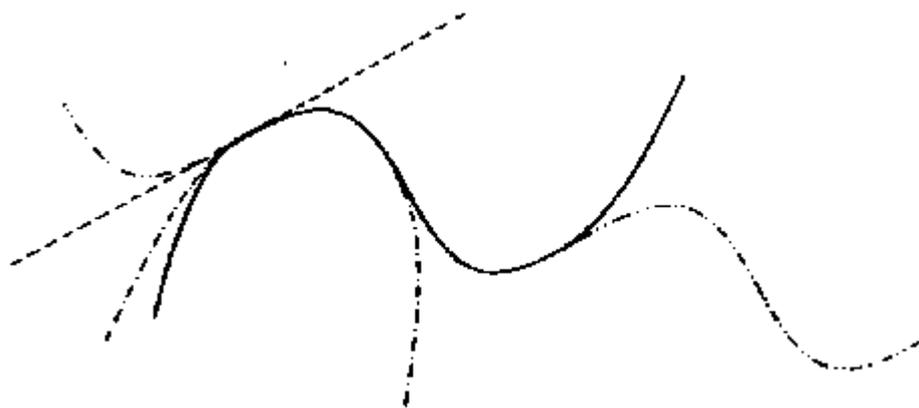

226 An hypothesis is a logical structure. That is, a symbol for which certain rules of representation hold.

Page 283

The point of talking of sense-data and immediate experience is that we're after a description that has nothing hypothetical in it. If an hypothesis can't be definitively verified, it can't be verified at all, and there's no truth or falsity for it [†1].

Page 283

My experience speaks in favour of the idea that *this* hypothesis will be able to represent it and future experience *simply*. If it turns out that another hypothesis represents the material of experience more simply, then I choose the simpler method. The choice of representation is a process based on so-called induction (not mathematical induction).

Page Break 284

Page 284

This is how someone might try to represent the course of an experience which presents itself as the development of a curve by means of various curves, each of which is based on how much of the actual course is known to us.

Page 284

The curve ----- is the actual course, so far as it is to be observed at all. The curves ---, -•-•-, -•••-, show different attempts to represent it that are based on a greater or lesser part of the whole material of observation.

Page 284

227 We only give up an hypothesis for an even higher gain.

Page 284

Induction is a process based on a principle of economy.

Page 284

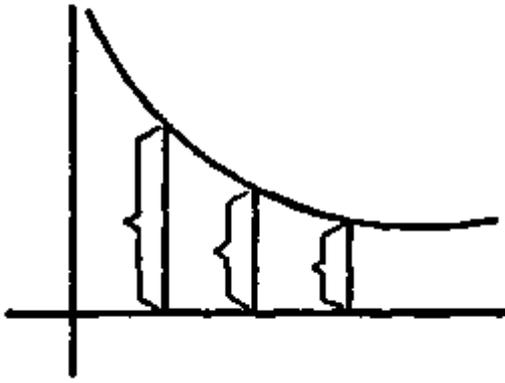

Any hypothesis has a connection with reality which is, as it were, looser than that of verification.

Page 284

The question, how simple a representation is yielded by assuming a particular hypothesis, is directly connected, I believe, with the question of probability.

Page 284

You could obviously explain an hypothesis by means of pictures. I mean, you could, e.g., explain the hypothesis, 'There is a book lying here', with pictures showing the book in plan, elevation and various cross-sections.

Page 284

Such a representation gives a *law*. Just as the equation of a curve gives a law, by means of which you may discover the ordinates, if you cut at different abscissae.

Page 284

In which case the verifications of particular cases correspond to cuts that have actually been made.

Page Break 285

Page 285

If our experiences yield points lying on a straight line, the proposition that these experiences are various views of a straight line is an hypothesis.

Page 285

The hypothesis is a way of representing this reality, for a new experience may tally with it or not, or possibly make it necessary to modify the hypothesis.

Page 285

228 What is essential to an hypothesis is, I believe, that it arouses an expectation by admitting of future confirmation. That is, it is of the essence of an hypothesis that its confirmation is never completed.

Page 285

When I say an hypothesis isn't definitively verifiable, that doesn't mean that there is a verification of it which we may approach ever more nearly, without ever reaching it. That is nonsense--of a kind into which we frequently lapse. No, an hypothesis simply has a different formal relation to reality from that of verification. (Hence, of course, the words 'true' and 'false' are also inapplicable here, or else have a different meaning.)

Page 285

The nature of the belief in the uniformity of events is perhaps clearest in a case where we are afraid of what we expect to happen. Nothing could persuade me to put my hand in the fire, even though it's *only in the past* that I've burnt myself.

Page 285

If physics describes a body of a particular shape in physical space, it must assume, even if tacitly, the possibility of verification. The points at which the hypothesis is connected with immediate experience must be anticipated.

Page 285

An hypothesis is a law for forming propositions.

Page 285

You could also say: An hypothesis is a law for forming expectations.

Page Break 286

Page 286

A proposition is, so to speak, a particular cross-section of an hypothesis.

Page 286

229 The probability of an hypothesis has its measure in how much evidence is needed to make it profitable to throw it out.

Page 286

It's only in this sense that we can say that repeated uniform experience in the past renders the continuation of this uniformity in the future probable.

Page 286

If, in this sense, I now say: I assume the sun will rise again tomorrow, because the opposite is so unlikely, I here mean by 'likely' and 'unlikely' something completely different from what I mean by these words in the

proposition 'It's equally likely that I'll throw heads or tails'. The two meanings of the word 'likely' are, to be sure, connected in certain ways, but they aren't identical.

Page 286

What's essential is that I must be able to compare my expectation not only with what is to be regarded as its definitive answer (its verification or falsification), but also with how things stand at present. This alone makes the expectation into a picture.

Page 286

That is to say: it must make sense *now*.

Page 286

If I say I can see, e.g., a sphere, that means nothing other than that I am seeing a view such as a sphere affords, but this only means I can construct views in accordance with a certain law--that of the sphere--and that this is such a view.

Page 286

230 Describing phenomena by means of the hypothesis of a world of material objects is unavoidable in view of its simplicity when compared with the unmanageably complicated phenomenological description. If I can see different discrete parts of a circle, it's perhaps impossible to give precise direct description of them, but the statement that they're parts of a circle, which, for reasons which haven't been gone into any further, I don't see as a whole--is simple.

Page Break 287

Page 287

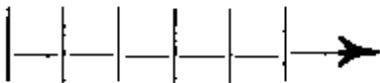

Description of this kind always introduces some sort of parameter, which for our purposes we don't need to investigate.

Page 287

What is the difference between the logical multiplicity of an explanation of appearances by the natural sciences and the logical multiplicity of a description?

Page 287

If e.g. a regular ticking sound were to be represented in physics, the multiplicity of the picture

would suffice, but here it's not a question of the logical multiplicity of the sound, but of that of the regularity of the phenomenon observed. And just so, the theory of Relativity doesn't represent the logical multiplicity of the phenomena themselves, but that of the regularities observed.

Page 287

If, for instance, we use a system of co-ordinates and the equation for a sphere to express the proposition that a sphere is located at a certain distance from our eyes, this description has a greater multiplicity than that of a verification by eye. The first multiplicity corresponds not to *one* verification, but to a *law* obeyed by verifications.

Page 287

As long as someone imagines the soul as a thing, a body in our heads, there's *no* harm in the hypothesis. The harm doesn't lie in the imperfection and crudity of our models, but in their lack of clarity (vagueness).

Page 287

The trouble starts when we notice that the old model is inadequate, but then, instead of altering it, only as it were sublimate it. While I say thoughts are in my head, everything's all right; it becomes harmful when we say thoughts aren't in my head, they're in my mind.

Page 287

Whatever someone *can* mean by a proposition, he also *may* mean by it. When people say, by the proposition 'There's a chair here', I don't merely mean what is shown me by immediate experience,

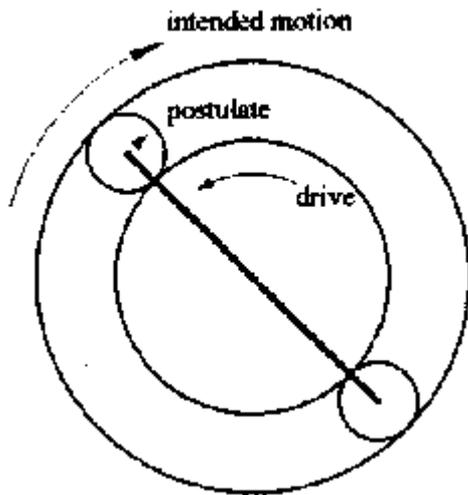

Page Break 288

but something over and above that, you can only reply: whatever you can mean must connect with some sort of experience, and whatever you *can* mean is unassailable.

Page 288

231 We may compare a part of an hypothesis with the movement of a part of a gear, a movement that can be stipulated without prejudicing the intended motion. But then of course you have to make appropriate adjustments to the rest of the gear if it is to produce the desired motion. I'm thinking of a differential gear.--Once I've decided that there is to be no deviation from a certain part of my hypothesis no matter what the experience to be described may be, I have stipulated a mode of representation and this part of my hypothesis is now a postulate. A postulate must be

such that no

conceivable experience can refute it, even though it may be extremely inconvenient to cling to the postulate. To the extent to which we can talk here of greater or slighter convenience, there is a greater or slighter probability of the postulate.

Page Break 289

Page 289

It's senseless to talk of a measure for this probability at this juncture. The situation here is like that in the case of two kinds of numbers where we can with a certain justice say that the one is more like the other (is closer to it) than a third, but there isn't any numerical measure of the similarity. Of course you could imagine a measure being constructed in such cases, too, say by counting the postulates or axioms common to the two systems, etc., etc.

Page 289

232 We may apply our old principle to propositions expressing a probability and say, we shall discover their sense by considering what verifies them.

Page 289

If I say 'That will probably occur', is this proposition verified by the occurrence or falsified by its non-occurrence? In my opinion, obviously not. In that case it doesn't say anything about either. For if a dispute were to arise as to whether it is probable or not, it would always only be arguments from the past that would be adduced. And this would be so even when what actually happened was already known.

Page 289

If you look at ideas about probability and its application, it's always as though *a priori* and *a posteriori* were jumbled together, as if the same state of affairs could be discovered or corroborated by experience, whose existence was evident *a priori*. This of course shows that something's amiss in our ideas, and in fact we always seem to confuse the natural law we are assuming with what we experience.

Page 289

That is, it always looks as if our experience (say in the case of card shuffling) agreed with the probability calculated *a priori*. But that is nonsense. If the experience agrees with the computation, that means my computation is justified by the experience, and of course it isn't its *a priori* element which is justified, but its bases, which are *a posteriori*. But those must be certain natural laws which I take as the basis for my calculation, and it is *these* that are confirmed, not the calculation of the probability.

Page Break 290

Page 290

The calculation of the probability can only cast the natural law in a different form. It transforms the natural law. It is the medium through which we view and apply the natural law.

Page 290

If for instance I throw a die, I can apparently predict *a priori* that the 1 will occur on average once every 6 throws, and that can then be confirmed empirically. But it isn't the calculation I confirm by the experiment, but the natural law which the probability calculation can present to me in different forms. Through the medium of the probability calculation I check the natural law lying behind the calculation.

Page 290

In our case the natural law takes the form that it is equally likely for any of the six sides to be the side

uppermost. It's this law that we test.

Page 290

233 Of course this is only a natural law if it can be confirmed by a particular experiment, and also refuted by a particular experiment. This isn't the case on the usual view, for if *any* event can be justified throughout an arbitrary interval of time, then *any* experience *whatever* can be reconciled with the law. But that means the law is idling; it's senseless.

Page 290

Certain possible events must contradict the law if it is to be one at all; and should these occur, they must be explained by a different law.

Page 290

When we wager on a possibility, it's always on the assumption of the uniformity of nature.

Page 290

If we say the molecules of a gas move in accordance with the laws of probability, it creates the impression that they move in accordance with some *a priori* laws or other. Naturally, that's nonsense. The laws of probability, i.e. those on which the calculation is *based*,

Page Break 291

are hypothetical assumptions, which are then rehashed by the calculation and then in another form empirically confirmed--or refuted.

Page 291

If you look at what is called the *a priori* probability and then at its confirmation by the relative frequency of events, the chief thing that strikes you is that the *a priori* probability, which is, as it were, something smooth, is supposed to govern the relative frequency, which is something irregular. If both bundles of hay are the same size and the same distance away, that would explain why the donkey stands still between them, but it's no explanation of its eating roughly as often from the one as from the other. *That* requires *different* laws of nature to explain it.--The facts that the die is homogeneous and that each side is exactly the same, and that the natural laws with which I'm familiar tell me nothing about the result of a throw, don't give me adequate grounds for inferring that the numbers 1 to 6 will be distributed roughly equally among the numbers thrown. Rather, the prediction that such a distribution will be the case contains an assumption about those natural laws that I don't know precisely: the assumption that *they* will produce such a distribution.

Page 291

234 Isn't the following fact inconsistent with my conception of probability: it's obviously conceivable that a man throwing dice every day for a week--let's say--throws nothing but ones, and not because of any defect in the die, but simply because the movement of his hand, the position of the die in the box, the friction of the table top always conspire to produce the same result. The man has inspected the die, and also found that when others throw it the normal results are produced. Has he grounds, now, for thinking that there's a natural law at work here which makes him throw nothing but ones? Has he grounds for believing that it's sure now to go on like this, or has he grounds for believing that this regularity can't last much longer? That is, has he grounds for abandoning the game since it has become clear that he can only

Page Break 292

throw ones, or for playing on since it is in these circumstances all the more probable that he will now throw a higher number? In actual fact, he will refuse to accept it as a natural law that he can throw nothing but ones. At least, it will have to go on for a long time before he will entertain this possibility. But why? I believe, because so much of his previous experience in life speaks against there being a law of nature of such a sort, and we have--so to speak--to surmount all that experience, before embracing a totally new way of looking at things.

Page 292

If we infer from the relative frequency of an event its relative frequency in the future, we can of course only do that from the frequency which has in fact been so far observed. And not from one we have derived from observation by some process or other for calculating probabilities. For the probability we calculate is compatible with *any* frequency whatever that we actually observe, since it leaves the time open.

Page 292

When a gambler or insurance company is guided by probability, they aren't guided by the probability calculus, since one can't be guided by this on its own, because *anything* that happens can be reconciled with it: no, the insurance company is guided by a frequency actually observed. And that, of course, is an absolute frequency.

Page 292

235 We can represent the equation of this curve:

as the equation of a straight line with a variable parameter, whose course expresses the deviations from a straight line. It isn't essential that these deviations should be 'slight'. They can be so large that the curve doesn't look like a straight line at all. 'Straight line with deviations' is *only one form* of description. It makes it possible for me to neglect a particular component of the description--if I so wish. (The form: 'rule with exceptions'.)

Page Break 293

Page 293

A Galtonian photograph is the picture of a probability [\dagger 1].

Page 293

A probability law is the natural law you see when you screw up your eyes.

Page 293

To say that the points yielded by this experiment distribute themselves around this curve--e.g. a straight line--means something like: seen from a certain distance, they appear to lie on a straight line.

Page 293

If I state 'That's the rule', that only has a sense as long as I have determined the maximum number of exceptions I'll allow before knocking down the rule.

Page 293

236 I can say of a curve  that the general impression is one of a straight line, but not of the curve  even though it might be possible to see this stretch in the course of a long stretch of curve in which its divergence from a straight line would be swallowed up.

Page 293

I mean: it only makes sense to say of the stretch you actually see (and not of an hypothetical one you assume) that it gives the general impression of a straight line.

Page 293

What is meant in a statistical experiment by 'in the long run'? An experiment must have a beginning and an end.

Page 293

An experiment with dice lasts a certain time, and our expectations for the future can only be based on tendencies we observe in what happens during this experiment. That is to say, the experiment can only give grounds for expecting that things will go on *in the way* shown by the experiment; but we can't expect that the experiment,

Page Break 294

if continued, will now yield results that tally better with a preconceived idea of its course than did those of the experiment we have actually performed.

Page 294

So if, for instance, I toss a coin and find no tendency in the results of the experiment itself for the numbers of heads and of tails to approximate to each other more closely, then the experiment gives me no reason to suppose that if it were continued such an approximation would emerge. Indeed, the expectation of such an approximation must *itself* refer to a definite point in time, since I can't expect something to happen *eventually*, without setting any finite limit whatever to the time when.

Page 294

I can't say: 'The curve  looks straight, since it could be part of a line which taken as a whole gives me the impression of a straight line.'

Page 294

237 Any 'reasonable' expectation is an expectation that a rule we have observed up to now will continue to hold.

Page 294

But the rule must have been observed and can't, for its part too, be merely expected.

Page 294

Probability Theory is only concerned with the state of expectation in the sense in which logic is with

thinking.

Page 294

Rather, probability is concerned with the form and a standard of expectation.

Page 294

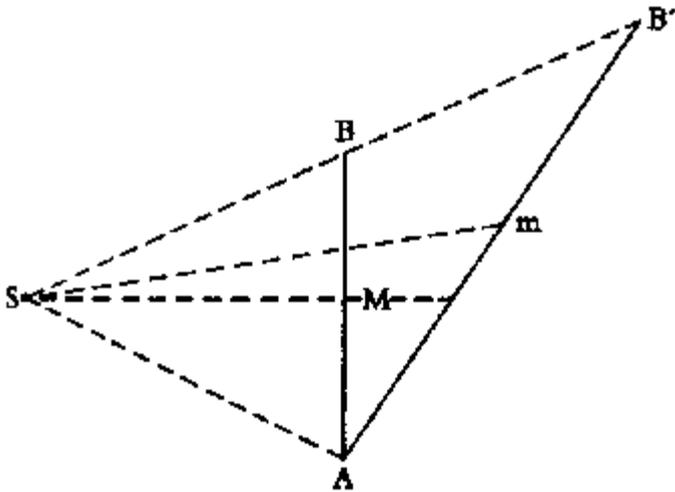

It's a question of expecting that future experience will obey a law which has been obeyed by previous experience.

Page 294

'It's likely that an event will occur' means: *something speaks in favour* of its occurring.

Page Break 295

238

Page 295

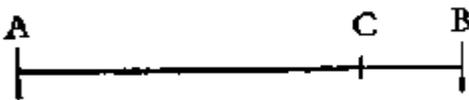

A ray is emitted from the light source S striking the surface AB to form a point of light there, and then striking the surface AB' to form one there. We have no reason to suppose that the point on AB lies to the left or to the right of M, and equally none for supposing that the point on AB' lies to the right or to the left of m; this yields apparently incompatible probabilities.

Page 295

But suppose I have made an assumption about the probability of the point on AB lying in AM, how is this assumption verified? Surely by a frequency experiment. Supposing this confirms the one view, then that is recognized as the right one and so shows itself to be an hypothesis belonging to *physics*. The geometrical construction merely shows that the fact that $AM = MB$ was *no* ground for assuming equal likelihood.

Page 295

I give someone the following piece of information, and no more: at such and such a time you will see a point of light appear in the interval AB.

Page 295

Does the question now make sense, 'Is it more likely that this point will appear in the interval AC than in CB?'' I believe,

Page Break 296

obviously not.--I can of course decide that the probability of the event's happening in CB is to be in the ratio CB/AC to the probability of its happening in AC; however, that's a decision I can have empirical grounds for making, but about which there is nothing to be said *a priori*. It is possible for the observed distribution of events not to lead to this assumption [†1]. The probability, where infinitely many possibilities come into consideration, must of course be treated as a limit. That is, if I divide the stretch AB into arbitrarily many parts of arbitrary lengths and regard it as equally likely that the event should occur in any one of these parts, we immediately have the simple case of dice before us. And now I can--arbitrarily--lay down a law for constructing parts of equal likelihood. For instance, the law that, if the lengths of the parts are equal, they are equally likely. But any other law is just as permissible.

Page 296

Couldn't I, in the case of dice too, take, say, five faces together as one possibility, and oppose them to the

sixth as the second possibility? And what, apart from experience, is there to prevent me from regarding these two possibilities as equally likely?

Page 296

Let's imagine throwing, say, a red ball with just one very small green patch on it. Isn't it much more likely in this case for the red area to strike the ground than for the green?--But how would we support this proposition? Presumably by showing that when we throw the ball, the red strikes the ground much more often than the green. But that's got nothing to do with logic.--We may always project the red and green surfaces and what befalls them onto a surface in such a way that the projection of the green surface is greater than or equal to the red; so that the events, as seen in this projection, appear to have a quite different probability ratio from the one they had on the original surface.

Page 296

If, e.g., I reflect the events in a suitably curved mirror and now imagine what I would have held to be the more probable event if I had only seen the image in the mirror.

Page 296

The one thing the mirror can't alter is the number of clearly

Page Break 297

demarcated possibilities. So that if I have n coloured patches on my ball, the mirror will also show n , and if I have decided that these are to be regarded as equally likely, then I can stick to this decision for the mirror image too.

Page 297

To make myself even clearer: if I carry out the experiment with a concave mirror, i.e., make the *observations* in a concave mirror, it will perhaps then look as if the ball falls more often on the small surface than on the much larger one; and it's clear that neither experiment--in the mirror or outside it has a claim to precedence.

Page 297

What now, does it really mean to decide that two possibilities are equally likely?

Page 297

Doesn't it mean that, first, the natural laws known to us give no preference to either of the possibilities, and second, that under certain conditions the relative frequencies of the two events approach one another?

Page Break 298

Written in 1931

Page Break 300

Page Break 301

Complex and Fact (June 1931)

Page 301

The use of the words 'fact' and 'act'.--'That was a noble act.'--'But, that never happened.'--

Page 301

It is natural to want to use the word 'act' so that it only corresponds to a *true* proposition. So that we then don't talk of an act which was never performed. But the proposition 'That was a noble act' must still have a sense even if I am mistaken in thinking that what I call an act occurred. And that of itself contains all that matters, and I can only make the stipulation that I will only use the words 'fact', 'act' (perhaps also 'event') in a proposition which, when complete, asserts that this fact obtains.

Page 301

It would be better to drop the restriction on the use of these words, since it only leads to confusion, and say quite happily: 'This act was never performed', 'This fact does not obtain', 'This event did not occur'.

Page 301

Complex is not like fact. For I can, e.g., say of a complex that it moves from one place to another, but not of a fact.

Page 301

But that this complex is now situated here is a fact.

Page 301

'This complex of buildings is coming down' is tantamount to: 'The buildings thus grouped together are coming down'.

Page 301

I call a flower, a house, a constellation, complexes: moreover, complexes of petals, bricks, stars, etc.

Page 301

That this constellation is located here, can of course be described by a proposition in which only its stars are mentioned and neither the word 'constellation' nor its name occurs.

Page 301

But that is all there is to say about the relation between complex and fact. And a complex is a spatial object, composed of spatial

Page Break 302

objects. (The concept 'spatial' admitting of a certain extension.)

Page 302

A complex is composed of its parts, the things of a kind which go to make it up. (This is of course a grammatical proposition concerning the words 'complex', 'part' and 'compose'.)

Page 302

To say that a red circle is *composed* of redness and circularity, or is a complex with these component parts, is a misuse of these words and is misleading. (Frege was aware of this and told me.)

Page 302

It is just as misleading to say the fact that this circle is red (that I am tired) is a complex whose component parts are a circle and redness (myself and tiredness).

Page 302

Neither is a house a complex of bricks and their spatial relations; i.e. that too goes against the correct use of the word.

Page 302

Now, you can of course point at a constellation and say: this constellation is composed entirely of objects with which I am already acquainted; but you can't 'point at a fact' and say this.

Page 302

'To describe a fact', or 'the description of a fact', is also a misleading expression for the assertion stating that the fact obtains, since it sounds like: 'describing the animal that I saw'.

Page 302

Of course we also say: 'to point out a fact', but that always means; 'to point out the fact that...'. Whereas 'to point at (or point out) a flower' doesn't mean to point out that this blossom is on this stalk; for we needn't be talking about this blossom and this stalk at all.

Page 302

It's just as impossible for it to mean: to point out the fact that this flower is situated there.

Page Break 303

Page 303

To point out a fact means to assert something, to state something. 'To point out a flower' doesn't mean this.

Page 303

A chain, too, is composed of its links, not of these and their spatial relations.

Page 303

The fact that these links are so concatenated, isn't '*composed*' of anything at all.

Page 303

The root of this muddle is the confusing use of the word 'object'.

Page 303

The part is smaller than the whole: applied to fact and component part (constituent), that would yield an absurdity.†*

Page Break 304

If you speak of the concept 'infinity', you must remember that this word has many different meanings and bear in mind which one we are going to speak of at this particular moment. Whether, e.g., of the infinity of a number series and of the cardinals in particular. If, for example, I say 'infinite' is a characteristic of a rule, I am referring to *one* particular meaning of the word. But we might perfectly well say a continuous transition of colour was a transition 'through infinitely many stages', provided we don't forget that here we are defining the meaning of the phrase 'infinitely many stages' *anew* by means of the experience of a colour transition. (Even if by analogy with other ways of using the word 'infinite'.)

(If we say that this area of our subject is extraordinarily difficult, that isn't true in the sense that we are, say, talking about things which are extraordinarily complicated or difficult to imagine, but only in the sense that it is extraordinarily difficult to negotiate the countless pitfalls language puts in our path here.)

I once said there was no extensional infinity. Ramsey replied: "Can't we imagine a man living for ever, that is simply, never dying, and isn't that extensional infinity?" I can surely imagine a wheel spinning and *never* coming to rest' [†1]. What a peculiar

argument: 'I can imagine...!' Let's consider what experience we would regard as a confirmation or proof of the fact that the wheel will never stop spinning. And compare this experience with that which would tell us that the wheel spins for a day, for a year, for ten years, and we shall find it easy to see the difference in the grammar of the assertions '... never comes to rest' and '... comes to rest in 100 years'. Let's think of the kind of evidence we might adduce for the claim that two heavenly bodies will orbit around one another, without end. Or of the Law of Inertia and how it is confirmed.

'Suppose we travel out along a straight line into Euclidean space and that at 10m. intervals we encounter an iron sphere, *ad. inf.*' [†1]. Again: What sort of experience would I regard as confirmation for this, and what on the other hand for there being 10,000 spheres in a row?--A confirmation of the first sort would be something like the following: I observe the pendulum movement of a body. Experiments have shown me that this body is attracted by iron spheres in accordance with a certain law; supposing there to be 100 such spheres in a series at a particular position with respect to the body under test would explain, on the assumption of this law of attraction, an approximation to the observed (or supposed) behaviour; but the more spheres we suppose there to be in the series, the more closely does the result calculated agree with the one observed. In that case, it makes sense to say experience confirms the supposition of an infinite series of spheres. But the difference between the sense of the statement of number and that of 'an infinite number' is as great as the difference between this experience and that of seeing a number of spheres.

'The merely negative description of not stopping cannot yield a positive infinity' [†2]. With the phrase 'a positive infinity' I

thought of course of a countable (= finite) set of things (chairs in this room) and wanted to say that the presence of a colossal number of such things can't be inferred from whatever it is that indicates to us that they don't stop. And so here in the form of my assertion I make the strange mistake of denying a fact, instead of denying that a particular proposition makes sense, or more strictly, of showing that two similar sounding remarks have different grammars.

What an odd question: 'Can we imagine an endless row of trees?!' If we speak of an 'endless row of trees', we will surely still link what we mean with the experiences we call 'seeing a row of trees', 'counting a row of trees', 'measuring a row of trees' etc. 'Can we imagine an endless row of trees?!' Certainly, once we have laid down what we are to understand by this; that is once we have brought this concept into relation with all these things, with the experiences which define for us the concept of a row of trees.

What in experience is the criterion for the row of trees being infinite? For that will show me how this assertion is to be understood. Or, if you give me no such criterion, what am I then supposed to do with the concept 'infinite row of trees'? What on earth has this concept to do with what I ordinarily call a row of trees? Or didn't you in the end only mean: an enormously long row of trees?

Page 306

'But we are surely familiar with an experience, when we walk along a row of trees, which we can call the row coming to an end. Well, an endless row of trees is one such that we never have this experience.'--But what does 'never' mean here? I am familiar with an experience I describe by the words 'He never coughed during the whole hour', or 'He never laughed in his whole life'. We cannot speak of an analogous experience where the 'never' doesn't refer to a time interval. And so once again analogy leaves us in the lurch here and I must try to find out *ab initio* how the word

Page Break 307

'never' can be used so as to make sense in this case.--Admittedly such uses can be found, but their rules are to be examined in their own right. For example, the proposition that a row of trees is infinitely long (or that we shall *never* come to its end), could be a natural law of the same sort as the Law of Inertia, which certainly says that under certain conditions a body moves in a straight line with constant velocity; and here it could indeed be said that under those conditions the movement will *never* end. But if we ask about the verification of such a proposition, the main thing to be said is that it is falsified if the movement (row of trees) comes to an end. There can be no talk of a verification here, and that means we are dealing with a fundamentally different kind of proposition (or with a proposition, in a different sense of that word). Naturally I don't want to say that this is the only significant use of the expression 'infinite row of trees' or of the word 'never' (in all eternity). But each such use must be described in its own right and has its own laws. It's no help to us that we find a way of speaking ready-made in our ordinary language, since this language uses each of its words with the most varied meanings, and understanding the use of the word in *one* context does not relieve us from investigating its grammar in another. Thus we think something like 'It is still surely possible to imagine an infinitely long life, for a man lives for an infinite length of time, if he simply never dies.' But the use of the word 'never' just isn't that simple.

Page 307

Let's now discuss an endless life in the sense of an hypothesis (cf. the Law of Inertia), and the man living it choosing in succession an arbitrary fraction from the fractions between 1 and 2, 2 and 3, 3 and 4, etc. *ad inf.* and writing it down. Does this give us a 'selection from all those intervals'? No,... /see above, §146, p. 167.

Page 307

'But now let's imagine a man who becomes more and more adept at choosing from intervals, so that he would take an hour for the first choice, half an hour for the second, a quarter for the third, etc. *ad inf.* In that case he would have done the whole job

Page Break 308

in two hours!' [†1] Let's now imagine the process. The choice would consist, say, in his writing down a fraction, and so in moving his hand. This movement would get quicker and quicker; but however quick it becomes, there will always be a last interval that has been dealt with in a particular time. The consideration behind our objection depends on forming the sum $1 + \frac{1}{2} + \frac{1}{4} + \dots$, but that is of course a *limit* of a series of sums, and not a sum in the sense in which, e.g., $1 + \frac{1}{2} + \frac{1}{4}$ is a sum. If I were to say 'He needs an hour for the first choice, half an hour for the second, a quarter for the third, etc. *ad. inf.*' then this remark only makes sense so long as I *don't* ask about the velocity of the choice at the time instant $t = 2$, since our reckoning gives no value for this (for there's no value $c = \text{infinity}$ here as far as we're concerned, since we haven't correlated any experience with it). My law gives me a velocity for any instant *before* $t = 2$, and so is to that extent applicable and in order. Thus the fallacy lies only in the sentence 'In that case he would have done the whole job in two hours'. (If we can call that a fallacy, since the sentence is in fact senseless in this context.)

Page 308

Let's now consider the hypothesis that under certain conditions someone will throw the digits of π (say, expressed in a system to the base 6). This hypothesis is, then, a law according to which I can work out for any throw the number of spots showing. But what if we modified the hypothesis into one that under certain conditions someone would *not* throw the digits of π ! Shouldn't that make sense too? But how could we ever know that this hypothesis was correct, since up to any given time he may have thrown in agreement with π , and yet this would not refute the hypothesis. But that surely just means that we have to do with a different *kind* of hypothesis; with a kind of proposition for which no *provision* is made in its grammar for a falsification. And it is open

to me to call that a 'proposition' or 'hypothesis' or something quite different, as I like. (π is not a decimal fraction, but a *law* according to which decimal fractions are formed.)

The infinity of time is not a duration.

If we ask 'What constitutes the infinity of time?' the reply will be 'That no day is the last, that each day is followed by another'. But here we are misled again into seeing the situation in the light of a false analogy. For we are comparing the succession of days with the succession of events, such as the strokes of a clock. In such a case we sometimes experience a fifth stroke following four strokes. Now, does it also make sense to talk of the experience of a fifth day following four days? And could someone say 'See, I told you so: I said there would be another after the fourth'? (You might just as well say it's an experience that the fourth is followed by the fifth and no other.) But we aren't talking here about the prediction that the sun will continue to move after the fourth day as before, *that's* a genuine prediction. No, in our case it's not a question of a prediction, no event is prophesied; what we're saying is something like this: that it makes sense, in respect of any sunrise or sunset, to talk of a next. For what is meant by designation of a period of time is of course bound up with something happening: the movement of the hand of a clock, of the earth, etc., etc.; but when we say 'each hour is succeeded by a next', having defined an hour by means of the revolution of a particular pointer (as a paradigm), we are still not using that assertion in order to prophesy that this pointer will go on in the same way for all eternity:--but we want to say: that it *can* go on in the same way for ever'; and that is simply an assertion concerning the grammar of our determinations of time.

Let's compare the propositions 'I'm making my plans on the assumption that this situation will last for two years' and 'I'm

making them on the assumption that this situation will last for ever'.--Does the proposition make sense 'I believe (or expect, or hope), that it will stay like that throughout infinite time'?

We may say: 'I am making arrangements for the next three days', or 10 years, etc., and also 'I'm making arrangements for an indefinite period';--but also 'for an infinite time'? If I 'make arrangements for an indefinite period', it is surely possible to mention a time for which at any rate I am no longer making arrangements. That is, the proposition 'I am making arrangements for an indefinite period' does not imply every arbitrary proposition of the form 'I am making arrangements for n years'.

Just think of the proposition: 'I *suspect* this situation will continue like this without end'!

Or how comical this rebuttal sounds: 'You said this clockwork would run for ever--well, it's already stopped *now*'. We feel that surely every finite prediction of too long a run would also be refuted by the fact, and so in some sense or other the refutation is incommensurable with the claim.--For it is nonsense to say 'The clockwork didn't go on running for an infinite time, but stopped after 10 years' (or, even more comically: '... but stopped after only 10 years').

How odd, if someone were to say: 'You have to be very bold to predict something for 100 years;--but how bold you must be to predict something for infinite time, as Newton did with his Law of Inertia!'

'I believe it will go on like that for ever'.--Isn't it enough (for all practical purposes) to say you believe it will go on like that for 10,000 years?--That is to say, we must ask: Can there be grounds for this belief? What are they? What are the grounds for assuming that it will go on for 1,000 more years; what for assuming it will go on for 10,000 more years;--and, now, what are the grounds for the infinite assumption?!--That's what makes the sentence 'I suspect it will go on without end' so comic; we want to ask, why do you suspect that? For we want to say it's senseless to say you suspect that: because it's senseless to talk of grounds for such a suspicion.

Let's consider the proposition 'This comet will move in a parabola with equation...'. How is this proposition used? It cannot be verified; that is to say: *we* have made no provision for a verification in its grammar (that doesn't of

course mean we can't say it's true; for ' p is true' says the same as ' p '). The proposition can bring us to make certain observations. But for those a finite prediction would always have done equally well. It will also determine certain actions. For instance, it might dissuade us from looking for the comet in such and such a place. But for that too, a finite claim would have been enough. The infinity of the hypothesis doesn't consist of its *largeness*, but in its open-endedness.

Page 311

'Eventually, the world will come to an end': an infinite hypothesis.

Page 311

The proposition that eventually--in the infinite future--an event (e.g. the end of the world) will occur, has a certain formal similarity with what we call a tautology.

Infinite Possibility

Page 311

Different use of the word 'can' in the propositions 'Three objects can lie in this direction' and 'Infinitely many objects can lie in this direction' [†1]. What sense, that is to say, what grammar could such a way of talking possess? We might for example say: 'In the natural number series 1, 2, 3, 4.... infinitely many numerals can follow the "1"'; that is tantamount to: 'The operation + 1 may be applied ever again (or: without end)'. And so if, for example, someone writes the numeral $100 + 1$ after the numeral 100, that rule gives him the right to do so. On the other hand, there is no

Page Break 312

sense here in saying: 'If it's permissible to write down infinitely many numerals, let's write infinitely many numerals (or try to)!'

Page 312

Analogously, if I say a division yields an infinite decimal fraction, then there isn't *one* result of the division called 'an infinite decimal', in the sense in which the number 0.142 is a result of $1 \div 7$. The division doesn't yield as its final result *one* decimal number, or a number of decimal numbers but rather we can't talk of 'its final result': it endlessly yields decimal fractions; not 'an endless decimal fraction'. 'Endlessly' not 'endless'.

Page 312

Let's now imagine the following case: I have constructed a particular kind of die, and am now going to predict: 'I shall throw the places of π with this die'. This claim is of a different form from the apparently similar 'I shall throw the first ten places of π with this die'. For in the second case there is a proposition 'I shall have thrown the first ten places of π within the hour', but this proposition becomes nonsense (not false), if I substitute 'the places' for 'the first ten places'. In the sentence 'Any arbitrary number of throws is possible', 'possible' may be equivalent to 'logically possible' ('conceivable'), and then it is a rule, not an empirical proposition, and is of a similar sort to that of the rule 'numerals can follow 1 without end'. But we might also construe it as a kind of empirical proposition, a kind of hypothesis: but then it would be the kind of hypothesis which has no verification provided for it, only a falsification, and so it would be a different kind of proposition (a 'proposition' in a different sense) from the empirical proposition: 'Three throws are possible with this die'. This--unlike the *rule* 'Three throws are conceivable'--would mean something like: 'The die will still be usable after three throws'; the hypothesis 'Infinitely many throws are possible with this die' would mean 'However often you throw it, this die will not wear out'. It's very clear that these propositions are different in kind, if you think of the nonsensical order 'Throw it infinitely often' or 'Throw *ad infinitum*', as opposed to the significant 'Throw it three times'. For it is essential to a command that we can check whether it has been carried out.

Page Break 313

Page 313

If we wish to say infinity is an attribute of possibility, not of reality, or: the word 'infinite' always goes with the word 'possible', and the like,--then this amounts to saying: the word 'infinite' is always a part of a *rule*.

Page 313

Let's suppose we told someone: 'I bought a ruler yesterday with infinite curvature'. Here, however, the word 'infinite' surely occurs in the description of a reality.--But still, I can never have the experience which would justify me in saying that the ruler actually had an infinite radius of curvature, since a radius of 100^{100} km would surely do just as well.--Granted, but in that case I can't have the experience which would justify me in saying the ruler is *straight* either. And the words 'straight' (or in another context 'parallel') and 'infinite' are in the *same* boat. I mean: If the word 'straight', ('parallel', 'equally long', etc., etc.) may occur in a description of reality, then so may the word 'infinite' [†1].

'All that's infinite is the possibility' means "'infinite" qualifies "etc.".' And so far as this is what it does, it belongs in a rule, a law. It's out of place in describing experience only when we mean by 'experience that corresponds to a law' an endless series of experiences.--The slogan 'all that's infinite is the possibility, not the reality' is misleading. We may say: '*In this case* all that's infinite is the possibility'.--And we justifiably ask: what is it that is infinite about this hypothesis (e.g. about the path of a comet)? Is there something huge about this assumption, this thought?

If we say 'The possibility of forming decimal places in the division $1 \div 3$ is infinite', we don't pin down a fact of nature, but give a rule of the system of calculation. But if I say: 'I give you infinite freedom to develop as many places as you like, I won't stop you', then this isn't enunciating the rule of the system of calculation, it's saying something about the future. 'Yes, but still only as the description of a possibility'.--No, of a reality! But *of*

course not that of 'infinitely many places'; to say that would be to fall into the very grammatical trap we must avoid.

The fact that it permits the endless formation of numerals doesn't make grammar infinitely complicated.

To explain the infinite possibility, it must be sufficient to point out the features of the sign which lead us to assume this infinite possibility, or better: from which we read off this infinite possibility. That is, what is actually present in the sign must be sufficient, and the possibilities of the sign, which once more could only emerge from a description of signs, do not come into the discussion [\dagger 1]. And so everything must be already contained in the sign '/1, x , $x + 1$ '--the expression for the rule of formation. In introducing infinite possibility, I mustn't reintroduce a mythical element into grammar. If we describe the process of division $1.0 \div 3 = 0.3$, which leads to the quotient 0.3 and remainder 1, the infinite possibility of going on with always the same result must be contained in this description, since we certainly aren't given anything else, when we see 'that it must always go on in the same way'.

And when we 'see the infinite possibility of going on', we still can't see anything that isn't described when we simply describe the sign we see.

APPENDIX 2

From F. Waismann's shorthand transcript of Wittgenstein's talks and conversation between December 1929 and September 1931.

Yardstick and System of Propositions

(From F. Waismann's notes for 25 December 1929.)

I once wrote: 'A proposition is laid like a yardstick against reality. Only the outermost tips of the graduation marks touch the object to be measured.' I should now prefer to say: a *system of propositions* is laid like a yardstick against reality. What I mean by this is: when I lay a yardstick against a spatial object, I apply *all the graduation marks simultaneously*. It's not the individual graduation marks that are applied, it's the whole scale. If I know that the object reaches up to the tenth graduation mark, I also know immediately that it doesn't reach the eleventh, twelfth, etc. The assertions telling me the length of an object form a system, a system of propositions. It's such a whole system which is compared with reality, not a single proposition. If, for instance, I say such and such a point in the visual field is *blue*, I not only know that, I also know that the point isn't green, isn't red, isn't yellow etc. I have simultaneously applied the whole colour scale. This is also the reason why a point can't have different colours simultaneously; why there is a syntactical rule against fx being true for more than one value of x . For if I apply a

system of propositions to reality, that of itself already implies--as in the spatial case--that in every case only *one* state of affairs can obtain, never several.

Page 317

When I was working on my book I was still unaware of all this and thought then that every inference depended on the form of a tautology. I hadn't seen then that an inference can also be of the form: A man is 6 ft tall, therefore he isn't 7 ft. This is bound up with my then believing that elementary propositions had to be independent of one another: from the fact that one state of affairs obtained you couldn't infer another did not. But if my present conception of a system of propositions is right, then it's even the rule that from the fact that one state of affairs obtains we can infer that all the others described by the system of propositions do not.

Page Break 318

Consistency

Page 318

(Waismann's notes, Wednesday, 17 December, 1930, Neuwaldegg. Transcript of Wittgenstein's words, unless otherwise indicated.)

Page 318

I've been reading a work by Hilbert on consistency. It strikes me that this whole question has been put wrongly. I should like to ask: *Can* mathematics be inconsistent at all? I should like to ask these people: Look, what are you really up to? Do you really believe there are contradictions hidden in mathematics?

Page 318

Axioms have a twofold significance, as Frege saw.

Page 318

1) The rules, *according to* which you play.

Page 318

2) The opening positions of the game.

Page 318

If you take the axioms in the second way, I can attach no sense to the claim that they are inconsistent. It would be very queer to say: this configuration (e.g. in the Hilbertian formula game, $0 \neq 0$) is a contradiction. And if I do call some configuration or other a contradiction, that has no essential significance, at least for the game *qua* game. If I arrange the rules so that this configuration can't arise, all I've done is made up a different game. But the game's a game, and I can't begin to understand why anyone should attach such great importance to the occurrence of this configuration: they behave as though this particular one were tabu. I then ask: and what is there to get excited about if this configuration does arise?

Page 318

The situation is completely different if the axioms are taken as the rules *according to* which the game is played. The rules are--in a certain sense--statements. They say: you may do this or this, but not that. Two rules can be inconsistent. Suppose, e.g., that in chess one rule ran: under such and such circumstances the piece concerned must be taken. But another rule said: a knight may never be taken. If now the piece concerned happens to be a knight, the

Page Break 319

rules contradict one another: I don't know what I'm supposed to do. What do we do in such a case? Nothing easier: we introduce a new rule, and the conflict is resolved.

Page 319

My point, then, is: if inconsistencies were to arise between the rules of the game of mathematics, it would be the easiest thing in the world to remedy. All we have to do is to make a new stipulation to cover the case in which the rules conflict, and the matter's resolved.

Page 319

But here I must make an important point. A contradiction is only a contradiction *when it arises*. People have the idea that there might at the outset be a contradiction hidden away in the axioms which no-one has seen, like tuberculosis: a man doesn't suspect anything and then one day he's dead. That's how people think of this case too: one day the hidden contradiction might break out, and then the catastrophe would be upon us.

Page 319

What I'm saying is: to ask whether the derivations might not eventually lead to a contradiction makes no sense at all as long as I'm given no method for discovering it.

Page 319

While I can play, I can play, and everything's all right.

The truth of the matter is that the calculus *qua* calculus is all right. It doesn't make any sense whatever to talk about contradiction. What we call a contradiction arises when we step outside the calculus and say in prose: 'Therefore all numbers have this property, but the number 17 doesn't have it.'

In the calculus the contradiction can't be expressed at all.

I can play with the chessmen according to certain rules. But I can also invent a game in which I play with the rules themselves. The pieces in my game are now the rules of chess, and the rules of the game are, say, the laws of logic. *In that case I have yet another game and not a metagame.* What Hilbert does is mathematics and not metamathematics. It's another calculus, just like any other.

(Sunday, 28 December 1930, at Schlick's home.)

The problem of the consistency of mathematics stems from two

sources: (1) From the idea of non-Euclidean geometry where it was a matter of proving the axiom of parallels by means of the given paradigm of a *reductio ad absurdum*. (2) From the Burali-Forti and Russellian antinomies.

The impetus behind the present preoccupation with consistency came mainly from the antinomies. Now, it has to be said that these antinomies haven't got anything to do with consistency in mathematics, that there's no connection here at all. For the antinomies didn't in fact arise in the calculus, but in ordinary everyday speech, precisely because we use words ambiguously. So that resolving the antinomies consists in replacing the vague idiom by a precise one (by reflecting on the strict meaning of the words). And so the antinomies *vanish* by means of an *analysis*, not of a *proof*.

If the contradictions in mathematics arise through an unclarity, I can *never dispel this unclarity by a proof*. The proof only proves what it proves. But it can't lift the fog.

This of itself shows that there can be no such thing as a consistency proof (if we are thinking of the inconsistencies of mathematics as being of the same sort as the inconsistencies of set theory), that the proof can't begin to offer what we want of it. If I'm unclear about the nature of mathematics, no proof can help me. And if I'm clear about the nature of mathematics, the question of consistency can't arise at all.

Russell had the idea that his 5 'primitive propositions' were to be both the basic configurations and the rules for going on. But he was under an illusion here, and this came out in the fact that he himself had to add further rules (in words!).

So we must distinguish: the basic configurations of the calculus (the opening positions of the game) and the rules telling us how to get from one configuration to another. This was already made clear by Frege in his critique of the theories of Heine and Thomae: 'How surprising. What would someone say if he asked what the rules of chess were and instead of an answer was shown a group of chessmen on the chessboard? Presumably that he couldn't find

a rule in this, since he didn't attach any sense at all to these pieces and their layout' (*Grundgesetze*, II, p. 113).

Now if I take the calculus as a calculus, the positions in the game can't represent contradictions (unless I arbitrarily call one of the positions that arise in the game a 'contradiction' and exclude it; all I'm doing in that case is declaring that I'm playing a *different* game).

The idea of inconsistency --this is what I'm insisting on--is contradiction [\dagger 1], and this can only *arise in the true/false* game, i.e. only where we are making assertions.

That is to say: A contradiction can only occur among the *rules of the game*. I can for instance have one rule saying the white piece must jump over the black one.

Now if the black is at the edge of the board, the rule breaks down. So the situation can arise where I don't

know what I'm meant to do. The rule doesn't tell me anything any more. What would I do in such a case? There's nothing simpler than removing the inconsistency: I must make a decision, i.e. introduce another rule.

Page 321

By permission and prohibition, I can always only define a game, never *the game*. What Hilbert is trying to show by his proof is that the axioms of arithmetic have the properties of *the game*, and that's impossible. It's as if Hilbert would like to prove that a contradiction is inadmissible.

Page 321

Incidentally, suppose two of the rules were to contradict one another. I have such a bad memory that I never notice this, but always forget one of the two rules or alternately follow one and then the other. Even in this case I would say everything's in order.

Page Break 322

The rules are instructions how to play, and as long as I can play they must be all right. They only cease to be all right the moment I *notice* that they are inconsistent, and the only sign for that is that I can't apply them any more. For the logical product of the two rules is a contradiction, and the contradiction no longer tells me what to do. And so the conflict only arises when I notice it. While I could play there was no problem.

Page 322

In arithmetic, too, we arrive at 'the edge of the chessboard', e.g. with the problem $\%$. (Were I to say $\% = 1$, I could prove $3 = 5$ and thus would come into conflict with the other rules of the game.)

Page 322

We see then that as long as we take the calculus as a calculus the question of consistency cannot arise as a serious question at all. And so is consistency perhaps connected with the *application* of the calculus? With this in mind, we must ask ourselves:

Page 322

What does it mean, to apply a calculus?

Page 322

It can mean two different things.

Page 322

1) We apply the calculus in such a way as to provide the grammar of a language. For, what is permitted or forbidden by the rules then corresponds in the grammar to the words 'sense' and 'senseless'. For example: Euclidean geometry construed as a system of syntactical rules according to which we describe spatial objects. 'Through any 2 points, a straight line can be drawn' means: a claim mentioning the line determined by these 2 points makes sense whether it happens to be true or false.

Page 322

A rule of syntax corresponds to the position in the game. (Can the rules of syntax contradict one another?) Syntax cannot be justified.

Page 322

2) A calculus can be applied so that *true* and *false* propositions correspond to the configurations of the calculus. Then the calculus yields a theory, describing something.

Page 322

Newton's three laws have a completely different significance from those of geometry. There is a verification for them--by experiments in physics. But there is no such thing as a justification for a game. That is highly important. You can construe geometry in this way too, by taking it as the description of actual measurements. Now we have claims before us, and claims can indeed be inconsistent.

Page Break 323

Page 323

Whether the theory *can* describe something depends on whether the logical product of the axioms is a contradiction. Either I see straight off that they form a contradiction, in which case the situation's clear; or I don't what then? Then there's a *hidden* contradiction present. For instance: Euclid's axioms together with the axiom 'The sum of the angles of a triangle is 181° '. Here I can't see the contradiction straight off, since I can't see straight off that a sum of 180° follows from the axioms.

Page 323

As long as we stay within the calculus, we don't have any contradiction. For $s = 180^\circ$, $s = 181^\circ$ don't contradict one another at all. We can simply make two different stipulations. All we can say is: the calculus is applicable to everything to which it is applicable. Indeed, even here an application might still be conceivable, e.g. in

such a way that, measured by one method, the sum of the angles of a triangle comes to 180° , and by another to 181° . It's only a matter of finding a domain whose description requires the multiplicity possessed by the axioms.

Page 323

Now if a contradiction occurs at this point in a *theory*, that would mean that the propositions of the theory couldn't be translated into statements about how a galvanometer needle is deflected, etc., any more. It might for instance come out that the needle stays still or is deflected, and so this theory couldn't be verified.

Page 323

Unlike geometrical equations, Maxwell's equations don't represent a calculus, they are a fragment, a part of a calculus.

Page 323

What does it mean, mathematics must be 'made secure' [\dagger 1]? What would happen if mathematics weren't secure? For is it any kind of claim at all, to say that the axioms are consistent?

Page 323

Can one look for a contradiction? Only if there is a method for looking. There can be no such question as whether we will ever come upon a contradiction by going on in accordance with the rules. I believe that's the crucial point, on which everything

Page Break 324

depends in the question of consistency.

Page 324

WAISMANN ASKS: But doesn't it make sense to ask oneself questions about an axiom system? Let's consider, for instance, the propositional calculus which Russell derives from 5 axioms. Bernays has shown one of these axioms is redundant, and that just 4 will do. He has gone on to show that these axioms form a 'complete system', i.e. that adding another axiom which can't be derived from these 4 makes it possible to derive any proposition you write down whatever. *This* comes down to the same thing as saying that every proposition follows from a contradiction. Now, isn't that a *material insight* into the Russellian calculus? Or, to take another case, I choose 3 axioms. I can't derive the same set of propositions from *these* as I can from all 5. Isn't that a material insight? And so can't you look upon a consistency proof as the recognition of something substantial?

Page 324

WITTGENSTEIN: If I first take 3 propositions and then 5 propositions, I can't compare the classes of consequences at all unless I form a *new system* in which both groups occur.

Page 324

And so it isn't as if I have both systems--the one with 3 axioms and the one with 5 axioms--in front of me and now compare them from outside. I can't do that any more than I can compare, say, the integers and the rational numbers until I've brought them into *one* system. And I don't gain a material insight either; what I do is once more to construct a calculus. And in this calculus the proposition 'The one class includes more than the other' doesn't occur at all: that is the prose accompanying the calculus.

Page 324

Can one ask: When have I applied the calculus? Is it possible for me not to know whether I have applied the calculus, and to have to wait until I have a consistency proof?

Page Break 325

Page 325

(Tuesday, 30 December, at Schlick's house)

WAISMANN reads out §117 and §118 of Frege's *Grundgesetze*.

Page 325

WITTGENSTEIN comments:

If one looks at this naïvely, the chief thing that strikes one is that mathematicians are always afraid of only *one* thing, which is a sort of nightmare to them: contradiction. They're not at all worried, e.g. by the possibility of a proposition's being a tautology, even though a contradiction is surely no worse than a tautology. In logic, contradiction has precisely the same significance as tautology, and I could study logic just as well by means of contradictions. A contradiction and a tautology of course *say* nothing, they are only a method for demonstrating the logical interrelations between propositions.

Page 325

It's always: 'the law [Satz] of contradiction'. I believe in fact that the fear of contradiction is bound up with its being construed as a *proposition* [Satz]: $\sim(p \bullet \sim p)$. There's no difficulty in construing the law of contradiction as a

rule: I forbid the formation of the logical product $p \cdot \sim p$. But the contradiction $\sim(p \cdot \sim p)$ doesn't begin to express this prohibition. How could it? The contradiction doesn't say anything at all, but the rule says something.

Page 325

WAISMANN REPEATS HIS QUESTION: You said that by prohibitions and permissions I can always only determine *a* game, but never *the* game. But is that right? Imagine for instance the case where I permit any move in chess and forbid nothing--would that still be a game? Mustn't the rules of a game then still have certain properties for them to define a game at all? Couldn't we then interpret the demand for consistency as one to exclude the 'tautological' game--the game in which anything is permissible? That is to say, if the formula ' $0 \neq 0$ ' can be derived by a legitimate proof and if in addition with Hilbert we add the axiom ' $0 \neq 0 \rightarrow \mathfrak{A}$ ', where \mathfrak{A} stands for an arbitrary formula, then we can derive the formula \mathfrak{A} from the inference pattern

$$\frac{0 \neq 0 \quad 0 \neq 0 \rightarrow \mathfrak{A}}{\mathfrak{A}}$$

Page Break 326

and write it down, too. But that means that in this case *any* formula can be derived, and so the game loses its character and its interest.

Page 326

WITTGENSTEIN: Not at all! There's a mistake here, i.e. a confusion between 'a rule of the game' and 'position in the game'. This is how it is: the game is tautological if the rules of the game are tautological (i.e. if they no longer forbid or permit anything); but that isn't the case here. This game, too, has its own particular rules: it's one game among many, and that the configuration ' $0 \neq 0$ ' arises in it is neither here nor there. It's just a configuration which arises in *this* game, and if I exclude it, then I have a *different* game before me. It simply isn't the case that in the first instance I don't have a game before me but in the second I do. One class of rules and prohibitions borders on another class of rules and prohibitions, but *a game doesn't border on a non-game*. The 'tautological' game must arise as the limit case of games, as their natural limit. The system of games must be delimited from within, and this limit consists simply in the fact that the rules of the game vanish. I can't get this limit case by myself setting up particular rules and prohibitions; for that just gives me once more one game among many. So if I say: The configuration ' $0 \neq 0$ ' is to be permitted, I am once more stating a rule, defining a game; merely a different one from the one where I exclude this configuration.

Page 326

That is to say: by rules I can never define *the* game, always only *a* game.

Page 326

WAISMANN ASKS: There's a theory of chess, isn't there? So we can surely use this theory to help us obtain information about the possibilities of the game--e.g. whether in a particular position I can force mate in 8, and the like. If, now, there is a theory of the game of chess, then I don't see why there shouldn't also be a theory of the game of arithmetic and why we shouldn't apply the propositions of this theory to obtain material information about the possibilities of this game. This theory is Hilbert's metamathematics.

Page Break 327

Page 327

WITTGENSTEIN: What is known as the 'theory of chess' isn't a theory describing something, it's a kind of geometry. It is of course in its turn a calculus and not a theory.

Page 327

To make this clear I ask you whether, in your opinion, there is a difference between the following two propositions: 'I can force mate in 8' and 'By the theory I have proved I can force mate in 8'? No! For if in the theory I use a symbolism instead of a chessboard and chess set, the demonstration that I can mate in 8 consists in my actually doing it in the symbolism, and so, by now doing with signs what I do with pieces on the board. When I make the moves and when I prove their possibility--then I have surely done *the same thing* over again in the proof. I've made the moves with symbols, that's all. The only thing missing is in fact the actual movement; and of course we agree that moving the little piece of wood across the board is inessential.

Page 327

I am doing in the proof what I do in the game, precisely as if I were to say: You, Herr Waismann, are to do a sum, but I am going to predict what digits will be your result: I then simply do the sum for my own part, only perhaps with different signs (or even with the same, which I construe differently). I can now work out the result of

the sum all over again; I can't come to the same result by a totally different route. It isn't as if you are the calculator and I recognize the result of your calculation on the strength of a *theory*. And precisely the same situation obtains in the case of the 'theory of chess'.

Page 327

And so if I establish in the 'theory' that such and such possibilities are present, I am again moving about within the game, not within a metagame. Every *step* in the calculus corresponds to a move in the game, and the whole difference consists only in the physical movement of a piece of wood.

Page 327

Besides, it is highly important that I can't tell from looking at the pieces of wood whether they are pawns, bishops, rooks, etc.

Page Break 328

I can't say: that is a pawn *and* such and such rules hold for this piece. No, it is the rules alone which *define* this piece: a pawn *is* the sum of the rules for its moves (a square is a piece too), just as in the case of language the rules define the logic of a word.

Page 328

WAISMANN RAISES THE OBJECTION: Good, I can see all that. But so far we have only been dealing with the case that the theory says such and such a position is possible. But what if the theory proves the *impossibility* of a certain position--e.g. the 4 rooks in a straight line next to one another? And just this sort of case is dealt with by Hilbert. In this case the theory simply cannot reproduce the game. The steps in the calculus no longer correspond to moves in the game.

Page 328

WITTGENSTEIN: Certainly they don't. But even in this case it must come out that the theory is a calculus, just a different one from the game. Here we have a *new* calculus before us, a calculus with a different multiplicity.

Page 328

In the first instance: *If I prove that I cannot do such and such, I don't prove a proposition, I give an induction.*

Page 328

I can *see* the induction *on the chessboard*, too. I'll explain in a moment what I mean by that. What I prove is that no matter how long I play I can't reach a particular position. A proof like that can only be made by induction. It is now essential for us to be quite clear about the nature of proof by induction.

Page 328

In mathematics there are two sorts of proof:

Page 328

1) A proof proving a particular formula. This formula appears in the proof itself as its last step.

Page 328

2) Proof by induction. The most striking fact here is that the proposition to be proved doesn't itself occur in the proof at all. That is to say, induction isn't a procedure leading to a proposition. Instead, induction shows us an infinite possibility, and the essence of proof by induction consists in this alone.

Page 328

We *subsequently* express what the proof by induction showed us as a proposition and in doing so use the word 'all'. But this proposition adds something to the proof, or better: the proposition stands

Page Break 329

to the proof as a sign does to what is designated. The proposition is a *name* for the induction. It goes proxy for it, it doesn't follow from it.

Page 329

You can also render the induction visible on the chessboard itself, e.g., by my saying I can go there and back, there and back, etc. But the induction no longer corresponds to a move in the game.

Page 329

So if I prove in the 'theory' that such and such a position cannot occur, I have given an induction which shows something but expresses nothing. And so there is also no proposition at all in the 'theory' which says 'such and such is impossible'.

Page 329

Now it will be said that there must still be some connection between the actual game and the induction. And there is indeed such a connection--it consists in the fact that once I have been given the proof by induction I will no longer try to set up this position in the game. Before I might perhaps have tried and then finally given up. Now I

don't try any more. It's exactly the same here as when I prove by induction that there are infinitely many primes or that $\sqrt{2}$ is irrational. The effect of these proofs on the actual *practice* of arithmetic is simply that people stop looking for a 'greatest prime number', or for a fraction equal to $\sqrt{2}$. But here we must be even more precise than this. *Could* people previously search at all? What they did had, to be sure, a certain likeness to searching, but was something of an entirely different sort; they did something, expecting that as a result something else would occur. But that wasn't searching at all, any more than I can search for a way of wagging my ears. All I can do is move my eyebrows, my forehead and such parts of my body in the hope that my ears will move as well. But I can't *know* whether they will, and thus I can't *search* for a way of making them.

Page 329

Within *the* system in which I tell that a number is prime, I can't even ask what the number of primes is. The question only arises when you apply the substantial form to it. And if you have discovered the induction, that's also something different from computing a number.

Page Break 330

Page 330

The inductions correspond to the formulae of algebra (calculation with letters)--for the reason that the internal relations between the inductions are the same as the internal relations between the formulae. The system of calculating with letters is a new calculus; but it isn't related to ordinary numerical calculation as a metacalculus to a calculus. *Calculation with letters isn't a theory*. That's the crucial point. The 'theory' of chess--when it investigates the impossibility of certain positions--is like algebra in relation to numerical calculation. In the same way, Hilbert's 'metamathematics' must reveal itself to be mathematics in disguise.

Page 330

Hilbert's proof: ('Neubegründung der Mathematik', 1922)

Page 330

'But if our formalism is to provide a complete substitute for the earlier theory which actually consists of inferences and statements, then material contradiction must find its formal equivalent' [†1] $a = b$ and $a \neq b$ are never to be simultaneously provable formulae.

Page 330

The demonstration of consistency on Hilbert's simple model does in fact turn out to be inductive: the proof shows us by induction the possibility that signs must continue to occur on and on \rightarrow .

Page 330

The proof lets us see something. But what it shows can't be expressed by a proposition. And so we also can't say: 'The axioms are consistent'. (Any more than you can say there are infinitely many primes. That is prose.)

Page 330

I believe giving a proof of consistency can mean only one thing: looking through the rules. There's nothing else for me to do. Imagine I give someone a long list of errands to run in the town. The list is so long that perhaps I have forgotten one errand and given another instead, or I have put together different people's errands. What am I to do to convince myself that the errands can be

Page Break 331

carried out? I have to run through the list. But I can't 'prove' anything. (We mustn't forget that we are only dealing here with the *rules* of the game and not with its configurations. In the case of geometry, it's perfectly conceivable that when I go through the axioms I don't notice the contradiction.) If I say: I want to check whether the logical product is a contradiction, this comes to the same thing. *Writing it out* in the form of a contradiction only makes the matter *easier*. If you now choose to call that a 'proof', you are welcome to do so: even then it is just a method of making it easier to check. But it must be said: in and of itself even such a proof cannot guarantee that I don't overlook something.

Page 331

No calculation can do what checking does.

Page 331

But suppose I search systematically through the rules of the game? The moment I work within a system, I have a calculus once more; but then the question of consistency arises anew. And so in fact there is nothing for me to do but inspect one rule after another.

Page 331

What would it mean if a calculus were to yield ' $0 \neq 0$ '? It's clear we wouldn't then be dealing with a sort of modified arithmetic, but with a totally different kind of arithmetic, one without the slightest similarity to cardinal

arithmetic. We couldn't then say: in such and such respects it still accords with our arithmetic (as non-Euclidean geometry does with Euclidean--here the modification of an axiom doesn't have such radical implications); no, there wouldn't be the slightest trace of similarity left at all. Whether I can apply such a calculus is another matter.

Page 331

Besides, there are various difficulties here. In the first instance, one thing isn't clear to me: $a = b$ surely only expresses the substitutability of b for a . And so the equation is a rule for signs, a rule of the game. Then how can it be an axiom, i.e. a position in the game? From this angle a formula such as $0 \neq 0$ is utterly unintelligible.

Page Break 332

For it would in fact mean: you can't substitute 0 for 0--am I then supposed to inspect whether perhaps the one 0 has a flourish which the other doesn't? What on earth does such a prohibition mean? It's the same story as if I say $a = a$. That too is rubbish, no matter how often it gets written down. Schoolmasters are perfectly right to teach their children that $2 + 2 = 4$, but not that $2 = 2$. The way children learn to do sums in school is already in perfect order and there's no reason to wish it any stricter. In fact it's also evident that $a = a$ means nothing from the fact that this formula is never used.

Page 332

If, when I was working with a calculus, I arrive at the formula $0 \neq 0$, do you think that as a result the calculus would lose all interest?

Page 332

SCHLICK: Yes, a mathematician would say such a thing was of no interest to him.

Page 332

WITTGENSTEIN: But *excuse* me! It would be enormously interesting that precisely this came out! In the calculus, we are always interested in the result. How strange! This comes out here--and that there! Who would have thought it? Then how interesting if it were a contradiction which came out! Indeed, even at this stage I predict a time when there will be mathematical investigations of calculi containing contradictions, and people will actually be proud of having emancipated themselves even from consistency.

Page 332

But suppose I want to apply such a calculus? Would I apply it with an uneasy conscience if I hadn't already proved there was no contradiction? But how can I ask such a question? If I can apply a calculus, I have simply applied it; there's no subsequent correction. What I can do, I can do. I can't undo the application by saying: strictly speaking that wasn't an application.

Page 332

Need I first wait for a consistency proof before applying a calculus? Have all the calculations people have done so far been really--*sub specie aeterni*--a hostage against fortune? And is it conceivable that a time will come when it will all be shown to be illegitimate? Don't I know what I'm doing? It in fact amounts to a wish to prove that certain propositions are not nonsense.

Page Break 333

Page 333

So the question is this: I have a series of propositions, e.g. $p, q, r...$ and a series of rules governing operations, e.g. \cdot, \vee, \sim , and someone asks: if you apply these rules concerning the operations to the given propositions, can you ever arrive at nonsense? The question would be justified if by 'nonsense' I mean contradiction or tautology. I must then make the rules for forming statements in such a way that these forms do not occur.

Page 333

(1 January 1931, at Schlick's house)

Is one justified in raising the question of consistency? The strange thing here is that we are looking for something and have no idea what it really is we are looking for. How, for example, can I ask whether Euclidean geometry is consistent when I can't begin to imagine what it would be for it to contain a contradiction? What would it be like for there to be a contradiction in it? This question has first to be answered before we investigate such questions.

Page 333

One thing is clear: I can only understand a contradiction [Widerspruch], if it is a contradiction [Kontradiktion] [\dagger]. So I put forward the case in which I have a series of propositions, let's say $p, q, r...$, and form their logical product. I can now check whether this logical product is a contradiction. Is *that* all the question of consistency amounts to? That would take five minutes to settle. Surely in this sense, no one can *doubt* whether the Euclidean axioms are consistent.

Page 333

But what else could the question mean? Perhaps: if we go on drawing inferences sooner or later we will arrive at a contradiction? To that we must say: Have we a method for discovering the contradiction? If not, then there isn't a question here at all. For we cannot search to infinity.

Page 333

WAISMANN: Perhaps we can still imagine something--namely the schema for indirect proof. By analogy, we transfer that to an axiom system. We must distinguish two things: a problem which can be formulated *within* mathematics, which therefore also already possesses a method of solution; and the idea which

Page Break 334

precedes and guides the construction of mathematics. Mathematicians do in fact have such guiding ideas even in the case of Fermat's Last Theorem. I'm inclined to think that the question of consistency belongs to this complex of pre-mathematical questioning.

Page 334

WITTGENSTEIN: What's meant by analogy? E.g. analogy with indirect proof? Here it's like the trisection of an angle. I can't look for a way to trisect an angle. What really happens when a mathematician concerns himself with this question? Two things are possible: (1) He imagines the angle divided into 3 parts (a drawing); (2) He thinks of the construction for dividing an angle into 2 parts, into 4 parts. And this is where the mistake occurs: people think, since we can talk of dividing into 2, into 4 parts, we can also talk of dividing into 3 parts, just as we can count 2, 3 and 4 apples. But trisection--if there were such a thing--would in fact belong to a completely different category, a completely different system, from bisection, quadrisection. In the system in which I talk of dividing into 2 and 4 parts I can't talk of dividing into 3 parts. These are completely different logical structures. I can't group dividing into 2, 3, 4 parts together since they are completely different forms. You can't count forms as though they were actual things. You can't bring them under one *concept*.

Page 334

It's like wagging your ears. The mathematician naturally lets himself be led by associations, by certain analogies with the previous system. I'm certainly not saying: if anyone concerns himself with Fermat's Last Theorem, that's wrong or illegitimate. Not at all! If, for instance, I have a method for looking for whole numbers satisfying the equation $x^2 + y^2 = z^2$, the formula $x^n + y^n = z^n$ can intrigue me. I can allow myself to be intrigued by a formula. And so I shall say: there's a *fascination* here but not a *question*. Mathematical 'problems' always fascinate like this. This kind of fascination is in no way the preparation of a calculus.

Page 334

WAISMANN: But what then is the significance of the proof of the consistency of non-Euclidean geometry? Let's think of the simplest case, that we give a model, say, of two-dimensional Riemannian

Page Break 335

geometry on a sphere. We then have a translation: every concept (theorem) of the one geometry corresponds to a concept (theorem) of the other. If now the theorems in the one case were to include a contradiction, this contradiction would also have to be detectable in the other geometry. And so we may say: the Riemannian axiom system is consistent provided the Euclidean one is. We have then demonstrated consistency relative to Euclidean geometry.

Page 335

WITTGENSTEIN: Consistency 'relative to Euclidean geometry' is altogether nonsense. What happens here is this: a rule corresponds to another rule (a configuration in the game to a configuration in the game). We have a *mapping*. Full stop! Whatever else is said is prose. One says: *Therefore* the system is consistent. But there is no 'therefore', any more than in the case of induction. This is once more connected with the proof being misconstrued, with something being read into it which it doesn't contain. The proof is the proof. *The internal relations in which the rules (configurations) of one group stand to one another are similar to those in which the rules (configurations) of the other group stand. That's what the proof shows and no more.*

Page 335

On *Independence*: Let's suppose we have 5 axioms. We now make the discovery that one of these axioms can be derived from the other four, and so was redundant. I now ask: What's the significance of such a discovery? I believe that the situation here is exactly as it is in the case of Sheffer's discovery that we can get by with one logical constant.

Page 335

Above all, let's be clear: the axioms define--when taken with the rules for development of the calculus--a group of propositions. This domain of propositions isn't also given to us in some other way, but only by the 5

axioms. So we can't ask: Is *the same* domain perhaps also defined by 4 axioms alone? For the domain isn't detachable from the 5 axioms. These 5 axioms and whatever derives from them are--so to speak--my whole world. I can't get outside of this world.

Page 335

Now how about the question: are these 5 axioms independent?

Page Break 336

I would reply: is there a method for settling this question? Here various cases can arise.

Page 336

1) There is no such method. Then the situation is as I've described it: All that I have are the 5 axioms and the rules of development. In that case I can't seek to find out whether one of these axioms will perhaps *ever* emerge as a consequence of the others. And so I can't raise the question of independence at all.

Page 336

2) But suppose now that one of the axioms does come out as the result of a proof, then we haven't at all proved that only 4 axioms are sufficient, that one is redundant. No, I can't come to this insight through a logical inference, I must *see* it, just as Sheffer *saw* that he could get by with one logical constant. I must see the new system in the system within which I am working and in which I perform the proof.

Page 336

It's a matter of seeing, not of proving. No proposition corresponds to what I see--to the possibility of the system. Nothing is claimed, and so neither is there anything I can prove. So if in this case I give 5 axioms where 4 would do, I have simply been guilty of an oversight. For I should certainly have been in a position to know at the outset that one of these 5 axioms was redundant, and if I have written it down all the same, that was simply a mistake. Granted, it isn't enough in this case simply to set up the axioms, we must also prove that they really are independent.

Page 336

Now Hilbert appears to adopt this last course in the case of geometry. However, one important point remains unclear here: is the use of models a *method*? Can I look for a model systematically, or do I have to depend on a happy accident? What if I can't find a model which fits?

Page 336

To summarize: The question whether an axiom system is independent only makes sense if there is a method for deciding the question. Otherwise we can't raise this question at all. And if,

Page Break 337

e.g., someone discovers one axiom to be redundant, then he hasn't proved a proposition, he has read a new system into the old one.

Page 337

And the same goes for consistency.

Page 337

Hilbert's axioms:

I.1 and I.2: 'Any two distinct points A, B define a straight line a '
'Any two distinct points on a straight line define that line.'

Page 337

I already don't know how these axioms are to be construed, what their logical form is.

Page 337

WAISMANN: You can of course write them as truth functions by saying, e.g.: 'for all x , if x is a point, then...', I believe, however, that we miss the real sense of the axioms in this way. We mustn't introduce the points one after another. It seems much more correct to me to introduce the points, lines, planes by means of co-ordinates as it were at one fell swoop.

Page 337

WITTGENSTEIN: That's my view too. But one thing I don't understand: What would it mean to say that these axioms form a contradiction? The position is that as they stand they can't yield a contradiction, unless I determine by a rule that their logical product is a contradiction. That is, the situation with contradiction here is just as it is with the incompatibility of the propositions: 'This patch is green' and 'This patch is red'. As they stand, these propositions don't contradict one another at all. They only contradict one another once we introduce a further rule of syntax forbidding treating both propositions as true. Only then does a contradiction arise. (Cf. above p. 323: the example with 'the sum of the angles of a triangle = 180° '.)

(September 1931)

WAISMANN ASKS: (You said earlier) there was no contradiction at all in the calculus. I now don't understand how that fits in with the nature of indirect proof, for this proof of course depends precisely on producing a contradiction in the calculus.

WITTGENSTEIN: What I mean has nothing at all to do with indirect proof. There's a confusion here. Of course there are contradictions in the calculus; all I mean is this: it makes no sense to talk of a *hidden* contradiction. For what would a hidden contradiction be? I can, e.g., say: the divisibility of 357, 567 by 7 is hidden, that is, as long as I have not applied the criterion--say the rule for division. In order to turn the divisibility from a hidden one into an open one, I need only apply the criterion. Now, is it like that with contradiction? Obviously not. For I can't bring the contradiction into the light of day by applying a criterion. Now I say: then all this talk of a hidden contradiction makes no sense, and the danger mathematicians talk about is pure imagination.

You might now ask: But what if one day a method were discovered for establishing the presence or absence of a contradiction? This proposition is very queer. It makes it look as if you could look at mathematics on an assumption, namely the assumption that a method is found. Now I can, e.g., ask whether a red-haired man has been found in this room, and this question makes perfect sense, for I can describe the man even if he isn't there. Whereas I can't ask after a method for establishing a contradiction, for I can only describe it (the method) once it's there. If it hasn't yet been discovered, I'm in no position to describe it, and what I say are empty words. And so I can't even begin to ask the question what would happen if a method were discovered.

The situation with the method for demonstrating a contradiction is precisely like that with Goldbach's conjecture: what is going on is a random attempt at constructing a calculus. If the attempt succeeds I have a calculus before me again, only a different one from that which I have used till now. But I still haven't proved the calculus is a calculus, nor can that be proved at all.

If someone were to describe the introduction of irrational

numbers by saying he had discovered that between the rational points on a line there were yet more points, we would reply: 'Of course you haven't discovered new points between the old ones: you have constructed new points. So you have a new calculus before you.' That's what we must say to Hilbert when he believes it to be a discovery that mathematics is consistent. In reality the situation is that Hilbert doesn't establish something, he lays it down. When Hilbert says: $0 \neq 0$ is not to occur as a provable formula, he defines a calculus by permission and prohibition.

WAISMANN ASKS: But still you said a contradiction can't occur in the calculus itself, only in the rules. The configurations can't represent a contradiction. Is that still your view now?

WITTGENSTEIN: I would say that the rules, too, form a calculus, but a different one. The crucial point is for us to come to an understanding on what we mean by the term contradiction. For if you mean one thing by it and I mean another, we can't reach any agreement.

The word 'contradiction' is taken in the first instance from where we all use it, namely from the truth functions, and mean, say, $p \bullet \sim p$. So in the first instance we can only talk of a contradiction where it's a matter of assertions. Since the formulae of a calculus are not assertions, there can't be contradictions in the calculus either. But of course you can stipulate that a particular configuration of the calculus, e.g. $0 \neq 0$, is to be called a contradiction. Only then there is always the danger of your thinking of contradiction in logic and so confounding 'contradictory' and 'forbidden'. For if I call a particular configuration of signs in the *calculus* a contradiction, then that only means that the formation of this configuration is forbidden: if in a proof you stumble upon such a formula, something must be done about it, e.g. the opening formula must be struck out.

In order to avoid this confusion, I should like to propose that in place of the word 'contradiction' we use a completely new sign which has no associations for us except what we have explicitly

laid down: let's say the sign S . *In the calculus, don't take anything for granted.* If the formula S occurs, as yet that has no significance at all. We have first to make further stipulations.

WAISMANN ASKS: An equation in arithmetic has a twofold significance: it is a configuration and it is a substitution rule. Now what would happen if in arithmetic or analysis a proof of the formula $0 \neq 0$ were to be found? Then arithmetic would have to be given a completely different meaning, since we wouldn't any longer be entitled to interpret an equation as a substitution rule. 'You cannot substitute 0 for 0' certainly doesn't mean anything. A disciple of Hilbert could now say: there you see what the consistency proof really achieves. Namely this proof is intended to show us that we are entitled to interpret an equation as a substitution rule.

WITTGENSTEIN: That, of course, is something it can't mean. Firstly: how does it come about that we may interpret an equation as a substitution rule? Well, simply, because the grammar of the word 'substitute' is the same as the grammar of an equation. That is why there is from the outset a parallelism between substitution rules and equations. (Both, e.g., are transitive.) Imagine I were to say to you 'You cannot substitute a for a '. What would you do?

WAISMANN: I wouldn't know what to think, since this claim is incompatible with the grammar of the word 'substitute'.

WITTGENSTEIN: Good, you wouldn't know what to think, and quite right too, for in fact you have a new calculus in front of you, one with which you're unfamiliar. If I now explain the calculus to you by giving the grammatical rules and the application, then you will also understand the claim 'You cannot substitute a for a '. You can't understand this claim while you remain at the standpoint of the old calculus. Now, if say the formula $0 \neq 0$ could be proved, that would only mean we have two different calculi before us: one calculus which is the grammar of the verb 'substitute', and another in which the formula $0 \neq 0$ can be proved. These two calculi would then exist alongside one another.

If someone now wanted to ask whether it wouldn't be possible

to prove that the grammar of the word 'substitute' is the same as the grammar of an equation, i.e. that an equation can be interpreted as a substitution rule, we should have to reply: there can be no question of a proof here. For how is the claim supposed to run which is to be proved? That I apply the calculus, after all, only means that I set up rules telling me what to do when this or that comes out in the calculus. Am I then supposed to prove that I have set up rules? For surely that's the only sense the question whether I have applied the calculus can have. I once wrote: the calculus is not a concept of mathematics.

WAISMANN: You said on one occasion that no contradictions can occur in the calculus. If, e.g., we take the axioms of Euclidean geometry and add in the further axiom: 'The sum of the angles of a triangle is 181° ', even this would not give rise to a contradiction. For it could of course be that the sum of the angles has two values, just as does $\sqrt{4}$. Now if you put it like that, I no longer understand what an indirect proof achieves. For indirect proof rests precisely on the fact that a contradiction is derived in the calculus. Now what happens if I lay down as an axiom an assumption which has been refuted by an indirect proof? Doesn't the system of axioms thus extended present a contradiction? For instance: in Euclidean geometry it is proved that you can only drop *one* perpendicular from a point onto a straight line, what's more by an indirect proof. For suppose there are two perpendiculars, then these would form a triangle with two right angles, the sum of whose angles would be greater than 180° , contradicting the well known theorem about the sum of the angles. If I now lay down the proposition 'there are two perpendiculars' as an axiom and add the rest of the axioms of Euclidean geometry--don't I now obtain a contradiction?

WITTGENSTEIN: Not at all. What is indirect proof? Manipulating signs. But that surely isn't everything. A further rule now comes in, too, telling me what to do when an indirect proof is performed. (The rule, e.g., might run: if an indirect proof has been performed,

all the assumptions from which the proof proceeds may not be struck out.) *Nothing is to be taken for granted here.*

Everything must be explicitly spelt out. That this is so easily left undone is bound up with the fact that we can't break away from what the words 'contradiction' etc. mean in ordinary speech.

Page 342

If I now lay down the axiom 'Two perpendiculars can be dropped from one point onto a straight line', the sign picture of an indirect proof is certainly contained in this calculus. But we don't use it as such.

Page 342

What then would happen if we laid down such an axiom? 'I'd reach a point where I wouldn't know how to go on.' Quite right, you don't know how to go on because you have a new calculus before you with which you are unfamiliar. A further stipulation needs making.

Page 342

WAISMANN: But you could always do that when an indirect proof is given in a normal calculus. You could retain the refuted proposition by altering the stipulation governing the use of indirect proof, and then the proposition simply wouldn't be refuted any more.

Page 342

WITTGENSTEIN: Of course we could do that. We have then simply destroyed the character of indirect proof, and what is left of the indirect proof is the mere sign picture.

Page 342

(December 1931)

WAISMANN formulates the problem of consistency:

Page 342

The significance of the problem of consistency is as follows: How do I know that a proposition I have proved by transfinite methods cannot be refuted by a finite numerical calculation? If, e.g., a mathematician finds a proof of Fermat's Last Theorem which uses essentially transfinite methods--say the Axiom of Choice, or the Law of the Excluded Middle in the form: either Goldbach's conjecture holds for all numbers, or there is a number for which it doesn't hold--how do I know that such a theorem can't be refuted by a counter-example? That is not in the least self-evident. And yet it is remarkable that mathematicians place so

Page Break 343

much trust in the transfinite modes of inference that, once such a proof is known, no one would any longer try to discover a counter example. The question now arises: Is this trust justifiable? That is, are we sure that a proposition which has been proved by transfinite methods can never be refuted by a concrete numerical calculation? That's the mathematical problem of consistency.

Page 343

I will at the same time show how the matter seems to stand to me by raising the analogous question for ordinary algebra. How do I know, when I have proved a theorem by calculating with letters, that it can't be refuted by a numerical example? Suppose, e.g., I've proved that $1 + 2 + 3 + \dots + n = [n(n + 1)]/2$ --how do I know this formula can survive the test of numerical calculation? Here we have precisely the same situation. I believe we have to say the following: the reason why a calculation made with letters and a numerical calculation lead to the same result, i.e., the reason why calculating with letters can be applied to concrete numbers, lies in the fact that the axioms of the letter calculus--the commutative, associative laws of addition etc.--are chosen from the outset so as to permit such an application. This is connected with the fact that we choose axioms in accordance with a definite recipe. That is, an axiom corresponds to an induction, and this correspondence is possible because the formulae possess the same multiplicity as the induction, so that we can project the system of induction onto the system of formulae. And so there is no problem in this case, and we can't raise the question at all whether a calculation with letters can even come into conflict with a numerical calculation. But what about analysis? Here there really seems at first sight to be a problem.

Page 343

WITTGENSTEIN: First of all: what are we really talking about? If by 'trust' is meant a disposition, I would say: that is of no interest to me. That has to do with the psychology of mathematicians. And so presumably something else is meant by 'trust'. Then it can only be something which can be written down in symbols. What we

Page Break 344

have to ask about seems to be the reason why two calculations tally. Let's take a quite simple example:

$$2 + (3 + 4) = 2 + 7 = 9$$

$$(2 + 3) + 4 = 5 + 4 = 9$$

I have here performed two independent calculations and arrived on both occasions at the same result. 'Independent' here means: the one calculation isn't a copy of the other. I have two different processes.

And what if they didn't agree? Then there's simply nothing I can do about it. The symbols would then just have a different grammar. The associative and commutative laws of addition hold on the basis of grammar. But in group theory it's no longer the case that $AB = BA$; and so, e.g., we couldn't calculate in two ways, and yet we still have a calculus.

This is how things are: I must have previously laid down when a calculation is to be correct. That is, I must state in what circumstances I will say a formula is proved. Now if the case arose that a formula counted as having been proved on the basis of one method, but as refuted on the basis of another, then that wouldn't in the least imply we now have a contradiction and are hopelessly lost; on the contrary we can say: the formula simply means different things. It belongs to two different calculi. In the one calculus it's proved, in the other refuted. And so we really have two different formulae in front of us which by mere accident have their signs in common.

A whole series of confusions has arisen around the question of consistency.

Firstly, we have to ask where the contradiction is supposed to arise: in the rules or in the configurations of the game.

What is a rule? If, e.g., I say 'Do this and don't do this', the other doesn't know what he is meant to do; that is, we don't allow a contradiction to count as a rule. We just don't call a contradiction a rule--or more simply the grammar of the word 'rule' is such that a contradiction isn't designated as a rule. Now if a contradiction

occurs among my rules, I could say: these aren't rules in the sense I normally speak of rules. What do we do in such a case? Nothing could be more simple: we give a new rule and the matter's resolved.

An example here would be a board game. Suppose there is one rule here saying 'black must jump over white'. Now if the white piece is at the edge of the board, the rule can't be applied any more. We then simply make a new stipulation to cover this case, and with that the difficulty is wiped off the face of the earth.

But here we must be even more precise. We have here a contradiction (namely between the rules 'white must jump over black' and 'you may not jump over the edge of the board'). I now ask: Did we possess a method for discovering the contradiction at the outset? There are two possibilities here:

1) In the board game this possibility was undoubtedly present. For the rule runs: 'In general...' If this means 'in this position and in this position...' then I obviously had the possibility right at the beginning of discovering the contradiction--and if I haven't seen it, that's my fault. Perhaps I've been too lazy to run through all the cases, or I have forgotten one. There's no serious problem present in this case at all. Once the contradiction arises, I simply make a new stipulation and so remove it. We can always wipe the contradiction off the face of the earth.

But whether there is a contradiction can always be settled by inspecting the list of rules. That is, e.g., in the case of Euclidean geometry a matter of five minutes. The rules of Euclidean geometry don't contradict one another, i.e., no rule occurs which cancels out an earlier one (p and $\sim p$), and with that I'm satisfied.

2) But now let's take the second case, that we have no such method. My list of rules is therefore in order. I can't see any contradiction. Now I ask: Is there now still any danger? It's out of the question. What are we supposed to be afraid of? A contradiction? But a contradiction is only given me with the method for discovering it. As long as the contradiction hasn't arisen, it's no concern of mine. So I can quite happily go on calculating. Would

the calculations mathematicians have made through the centuries suddenly come to an end because a contradiction had been found in mathematics? Would we say they weren't calculations? Certainly not. If a contradiction does arise, we will simply deal with it. But we don't need to worry our heads about it *now*.

What people are really after is something quite different. A certain paradigm hovers before their mind's eye, and they want to bring the calculus *into line with this paradigm*.

EDITOR'S NOTE

Page 347

Our text is a typescript that G. E. Moore gave us soon after Wittgenstein's death: evidently the one which Wittgenstein left with Bertrand Russell in May, 1930, and which Russell sent to the Council of Trinity College, Cambridge, with his report in favour of a renewal of Wittgenstein's research grant.[†1] All the passages in it were written in manuscript volumes between February 2nd, 1929, and the last week of April, 1930. The latest manuscript entry typed and included here is dated April 24th, 1930. On May 5th, 1930, Russell wrote to Moore that he had 'had a second visit from Wittgenstein.... He left me a large quantity of typescript which I am to forward to Littlewood as soon as I have read it.' [J. E. Littlewood, F.R.S., Fellow of Trinity College.] In his report to the Council, dated May 8th, Russell says he spent five days in discussion with Wittgenstein, 'while he explained his ideas, and he left with me a bulky typescript, *Philosophische Bemerkungen*, of which I have read about a third. The typescript, which consists merely of rough notes, would have been very difficult to understand without the help of the conversations'. The Council had authorized Moore to ask Russell for a report, and I suppose they asked Moore to return the typescript to Wittgenstein. Wittgenstein asked Moore to take care of it. Apparently he did not keep a copy himself.

Page 347

Wittgenstein had made an earlier visit to Russell, in March, 1930, and Russell wrote to Moore then that 'he intends while in Austria to make a synopsis of his work which would make it much easier for me to report adequately..... He intends to visit me again in Cornwall just before the beginning of the May term, with his synopsis'. Wittgenstein can hardly have called the *Bemerkungen* a synopsis when he gave it to Russell; nor did Russell when he wrote to Moore and then to the Council about it. On the other hand it

Page Break 348

is a selection and a rearrangement of passages from what he had in manuscript and in typescript at the time. It was made from slips cut from a typescript and pasted into a blank ledger in a new order. The 'continuous' typescript was made from Wittgenstein's manuscript volumes I, II, III and the first half of IV. In the typing Wittgenstein left out many of the manuscript passages--more from I and II than from the others. In this typing he changed the order of some large blocks of material. This was nothing like his rearrangement of the slips he cut from it for the *Philosophische Bemerkungen* as Moore gave it to us.

Page 348

It was not 'merely rough notes'. But it was not easy to read, and Wittgenstein would not have published it without polishing. No spacing showed where a group of remarks hang closely together and where a new topic begins. Paragraphs were not numbered. And it was hard to see the arrangement and unity of the work until one had read it a number of times. (Russell did not have time to read it through once.) If he had thought of making this typescript more *übersichtlich* Wittgenstein might have introduced numbers for paragraphs, as he did in the *Brown Book* and in the *Investigations*. He might have divided into chapters, as he did with the typescript of 1932/33 (No. 213)--although he never did this again. (See Part II of *Philosophische Grammatik*.) The 1932/33 typescript was the only one for which he made a table of contents. We cannot guess whether he would have tried to do this for the *Philosophische Bemerkungen*. For the *Blue Book* he gave neither numbers nor chapter divisions. If he did at first think of the *Bemerkungen* which he left with Russell as a 'synopsis' of his writing over the past 18 months, he might have thought of some system of numbering (I am thinking of the *Tractatus*) which would show the arrangement. But I have found no reference or note in this sense.

Page 348

He went on writing directly after he had seen Russell--from the entries in the manuscript volume you would think there had not been a break. He had kept a copy of the typescript he had cut into slips to form the *Philosophische Bemerkungen*. (The top copy, in fact--and the least legible, for the first 60 pages of it: his typewriter ribbon was exhausted and hardly left ink marks. Later he used to dictate to a professional typist.) In a number of places he

Page Break 349

added to what he had typed or revised it--writing in pencil or ink on the back of the typed sheets or between the lines or in the margins. And in certain places he took pages from this copy and cut sections from it--pasting them into manuscript books or clipping them together with slips from other typescripts to form the 1932/33 typescript. In one or two places I have quoted a pencilled revision in a footnote here. But I do not think generally that the revisions he made there can be counted as revisions of the typescript (with its title page and motto) which he had left with

Russell. They belonged to a far-reaching change and development in Wittgenstein's thinking, and a different book.

Page 349

He had arrived in Cambridge sometime in January, 1929, and began his first manuscript volume on February 2nd. (Manuscript 'volume', as distinct from 'notebook': it was generally a hard covered notebook, often a large ledger. Such a volume is never rough notes, as the paper-covered and pocket notebooks often are.) Volumes I and II cannot be separated, for he wrote at first on the right-hand pages only; when he reached the end of volume II in this way he continued what he was writing on the *left*-hand pages of volume II, and when he came to the end of the volume on this side he continued on the left-hand pages of volume I--and on to the end of I. Volume III begins where this leaves off. He started III at the end of August or the beginning of September, 1929. (After the first week he did not date his entries in I and II. The first date in III comes on page 87 of the manuscript. It is: 11.9.29.)

Page 349

He wrote *Some Remarks on Logical Form* to read to the Aristotelian Society and Mind Association Joint Session in July, 1929--but he disliked the paper and when the time came he ignored it and talked about infinity in mathematics. In volumes I and II there are discussions of suggestions he makes in the *Logical Form* paper. The *Philosophische Bemerkungen* has a few of these; but many--those central to the paper, I think--are left out. Some remarks about 'phenomenological language' may refer to the earlier view in that paper. And the first sentence in §46 may refer to the example using coordinates there.

Page 349

In Appendix I: Wittgenstein's typescript of 'Complex and Fact'

Page Break 350

(*Komplex und Tatsache*) is taken from manuscript volume VI, in an entry dated 30.6.31.--more than a year after the last passage in the *Bemerkungen*. It is the first of three sections of what he had put together as a single typescript (now printed together in *Philosophische Grammatik*). These are numbered consecutively as forming a single essay, although they do not come close to one another in the manuscripts. 'Infinitely Long' and 'Infinite Possibility' are numbered consecutively, as though forming one essay, as well. Both groups seem to have been typed along with the 1932/33 typescript and Wittgenstein kept them together with it, but they do not form part of it.

Page 350

Of the two sections that *follow* 'Complex and Fact' in the typescript, about two-thirds of the remarks are here in *Philosophische Bemerkungen*, especially §93 to the end of §98. In the manuscript (volume VI) the discussion of 'complex \neq fact' grows out of 'I describe the fact which would be the fulfilment' of an order or of an expectation--and the apparent difficulty that this description is 'general in character', whereas the 'fulfilment' when it arrives is something you can point to. As though I had painted the apple that was going to grow on this branch, and now the apple itself is there: as though the grown apple was the event I was expecting. But the apple is not an event at all. 'The fact (or event) is described in general terms.' But then the fact is treated as though it were on all fours with a house or some other sort of complex. I expected the man, and my expectation is fulfilled. But *the man I expected* is not the fulfilment; but *that he has come*. This leads directly to 'complex \neq fact'. And this was important for the understanding of '*describing*'.

Page 350

Expectation and fulfilment have a different role in mathematics--not like their role in experience. And in mathematics there is not this distinction.

'In mathematics description and object are equivalent. "The fifth number in this series of numbers has these properties" says the *same* as "5 has these properties". The properties of a house do not *follow* from its position in a row of houses; but the properties of a number are the properties of a position.'

Page 350

You cannot *describe* what you expect to happen in the development of a decimal fraction, except by writing out the calculation

Page Break 351

in which it comes. Wittgenstein used to put this by saying 'the description of a calculation accomplishes the same as the calculation; the description of a language accomplishes the same as the language'.

Page 351

The passage I have quoted comes just before the discussion of 'Infinitely Long' in the manuscript (volume IX). Revising his account of 'description' brought with it a revision of the account of the *application* of mathematics, and especially of the use of expressions like 'infinity' in the mathematical sense for the description of physical happenings.

TRANSLATORS' NOTE

Page 352

This note, like the translation itself, runs the risk of overlying and obscuring the original. Yet we very much wish to express our thanks for help received, and we also feel we should mention one or two significant areas where we are conscious of having only half-resolved the difficulties of translation.

Page 352

Wittgenstein's style often depends on repeating certain words or groups of words in order to create a series of sometimes unexpected interrelations and back-references within the discussion. Some of these terms, e.g. *Raum* [space], have a straightforward English equivalent, whereas others prove less tractable. In such cases to use the same word in English throughout would unduly strain against the natural bent of English usage, whilst varying the English equivalents blunts the point of Wittgenstein's remarks. One term important enough to single out is *Bild*: 'picture' covers much the same area as this term in Wittgenstein's usage, but various phrases, e.g. *Erinnerungsbild* [memory image] are beyond its natural scope. For *Maßstab* we have usually said 'yardstick', since like *Maßstab* it can be used to convey a general notion of measure or standard whilst retaining, to some degree, its characteristics as a measure of length. At times these characteristics come into their own, for instance when Wittgenstein says someone shows his understanding of the notion of height in that he knows it is measured by a *Maßstab* and not by a weighing machine. At another point he reflects that the yardstick [*Maßstab*] needn't of course be a yardstick, it could equally well be a dial or scale with a needle. And, of course, it isn't strictly correct to say that the application is what makes a stick into a yardstick, it makes a stick (of any length) into a measuring stick, or a rod into a measuring rod [*Maßstab*]. Occasionally, we felt that 'ruler' or 'measure' would be more natural--neither of us thought people would keep yardsticks in their pockets--and that such mild variation in equivalents might possibly emphasize the unity of the underlying principle: they are all standards of measurement. A word curiously

Page Break 353

difficult to translate is *suchen*: 'seek', 'search (for)' and 'look (for)' all create difficulties, the first because it has the wrong kind of resonance, the others because of the occurrence of such sentences as 'Tell me how you *suchen*, and I will tell you what you *suchen*'. 'Tell me how you are searching and I will tell you what you are searching for' throws unwanted emphasis on 'for', and it is obvious that 'looking' and 'looking for' don't fit in with this pattern of syntax. We have generally said 'proposition' for *Satz*, but some contexts ask for 'sentence' in English and others for 'theorem'. In such cases important links are lost, and wherever it seemed appropriate we have indicated this fact. The word *Übersichtlichkeit*, which occurs at the beginning of the book, must have given trouble to all translators, who have variously rendered it as 'perspicuity', 'surveyability' and 'synoptic view', whereas we have rendered it freely as 'bird's-eye view'. The idea at stake here is that a range of phenomena is made *übersichtlich* or *übersehbar* when presented in such a way that we can simultaneously grasp the phenomena individually and as a whole, i.e. if their interrelations can be seen or surveyed in their entirety (you could say in *RFM* that a proof is *übersehbar* if it may be taken in as a single proof). Although differing from the German in that it suggests the elimination of the less important elements, 'bird's-eye view' seems to work well enough in our context. However, in view of the use Wittgenstein later makes of this concept, we felt we should signal its presence in the German text and express the hope that 'bird's-eye view' has something of its immediacy and simplicity.

Page 353

In preparing this translation we have received help and encouragement from a number of people, especially members of the Philosophy Department in the University of Leeds, and also members of the German Department. We are indebted to Mrs Inge Hudson for some suggestions about German usage and particularly to Peter Long for suggesting apt and pleasing ways of catching the force of the original at a number of points. Finally, we owe a special debt of gratitude to Rush Rhees for allowing us a completely free hand with the translation and for making considered and valuable suggestions on virtually every paragraph. We hope that these remarks indicate in some degree the extent to which we have benefited from his generosity.

Page Break 354

Page 354

This is a translation of the German edition of *Philosophische Bemerkungen*, edited by Rush Rhees, published Oxford 1964. The only divergences are a few additional footnotes requested by Rush Rhees. The following list of *Corrigenda* to the German edition was prepared by Rush Rhees and ourselves.

Page 354

FOOTNOTES

Page 52

†1] German: Die Oktaeder-Darstellung ist eine *übersichtliche* Darstellung der grammatischen Regeln.

Page 52

†2] German: Unserer Grammatik fehlt es vor allem an *Übersichtlichkeit*.

Page 110

†1] cf. Appendix, p. 317.

Page 124

†1] In the manuscript *W.* precedes this formula by the following definitions:

$$(\exists x)\phi x \stackrel{\text{Def}}{=} (\exists 1)_x\phi(x)$$

$$(\exists x, y)\phi x.\phi y \stackrel{\text{Def}}{=} (\exists 1 + 1)_x\phi(x)$$

$$(\exists x, y, z)\phi x \cdot \phi y \cdot \phi z \stackrel{\text{Def}}{=} (\exists 1 + 1 + 1)_x\phi(x)$$

etc.

further:

$$(\exists n)_x\phi(x) \cdot \sim (\exists n + 1)_x\phi(x) \stackrel{\text{Def}}{=} (n)_x\phi x'$$

and then leads into the formula in the text with the words 'Then you can e.g. write:...' ['Dann kann man z. B. schreiben:...'].]

Page 126

†1] In the manuscript Wittgenstein first wrote 'the proposition *A*' as follows:

Page 126

' $(\exists 2x)\phi x \cdot (\exists 2x)x \cdot \text{Ind.} \supset (\exists 4x)\phi x \vee \psi x \text{--}A$. This proposition doesn't--of course--say that $2 + 2 = 4$ but that the expression is a tautology shows it. ϕ and ψ must be disjoint variables.'

Page 126

He also writes in this connection: 'For isn't ' $(\exists 2x)\phi x \cdot (\exists 2x)\psi x \cdot \text{Ind.} (\exists 4x)\phi x \vee \psi x$ ' an application of $2 + 2 = 4$, just as much as ' $(\exists 2x)\phi x$ etc., etc.'?"

Page 126

By this stage he is using ' $(\exists 2x)\phi x$ ' in contrast with ' $(\exists 2x)\phi x$ ' to mean 'There are exactly two ϕ s', as opposed to 'There are at least two ϕ s'.

Page 128

†1] (Later marginal note): That we can make the calculus with strokes and without tautologies shows we do not need tautologies for it. Everything that does not belong to the number calculus is mere decoration.

Page 129

†1] (Later correction):... only direct insight into the number calculus can tell us... (with a mark of dissatisfaction under the words 'direct insight').

Page 129

†2] (Later marginal note): Instead of a question of the definition of number, it's only a question of the grammar of numerals.

Page 143

†1] Grelling's.

Page 144

†1] 'Chromatic number': a fictitious designation of a number that is perhaps not given by any law or calculation. In the manuscript, W. wrote, among other things:

Page 144

You could ask: What does $(x)2x = x + x$ say? It says that all equations of the form $2x = x + x$ are correct. But does that mean anything? May one say: Yes, I see that all equations of this form are correct, so now I may write ' $(x)2x = x + x$ '?

Page 144

Its meaning must derive from its proof. What the proof proves--that is the meaning of the proposition (neither more nor less)...

Page 144

An algebraic proof is the general form of a proof which can be *applied* to any number. If, referring to this proof, I say I have demonstrated that there is no chromatic number, then this proposition obviously says something other than ' $\sim(\exists n)\bullet\text{Chr } n$ '.

Page 144

And in that case what does the proposition '*There is a chromatic number*' say? It ought, surely, to say the opposite of what was demonstrated by the proof. But then, it doesn't say ' $(\exists n)\bullet\text{Chr } n$ '.

Page 144

If you make the wrong transition from the variable proposition to the general proposition (in the way Russell and Whitehead said was permissible), then the proof looks as if it's only a source for knowledge of the general proposition, instead of an analysis of its actual sense.

Footnote Page Break 145

Page 145

Then you could also say: perhaps the proposition is correct, even though it can't be proved.

Page 145

If this proof yields the proposition $Fa \neq fa$, what in this case is its opposite? (Surely--in our sense--not $Fa = fa$).

Page 145

Indeed, I have here only a form that I have proved possesses certain properties. On the strength of these properties, I can use it now in certain ways, viz. to show in any particular case that the number in question isn't chromatic. I can, of course, negate that form, but that doesn't give me the sense I want, and all I can do now is to deny the proof. But what does that mean? It doesn't of course, mean that it was wrongly--fallaciously--executed, but that it can't be carried out. That then means: the inequality doesn't derive from the forms in question; the forms do not exclude the inequality. But then, what else does? Does the development depend then on something further? That is, can the case arise in which the equation doesn't hold, and the form doesn't exclude it?

Page 149

†1] (Later marginal note): Is ' $(\exists n) 4 + n = 7$ '... α a disjunction? No, since a disjunction wouldn't have the sign 'etc. *ad inf.*' at the end but a term of the form $4 + x$.

Page 149

α is neither the same sort of proposition as 'There are men in this house', nor as 'There's a colour that goes well with this', nor as 'There are problems I find too difficult for me', nor as 'There's a time of day when I like to go for a walk'.

Page 150

†1] In the manuscript: 'that *all* propositions, $\sim p$, $\sim\sim p$, $\sim\sim\sim p$, etc. say the same.'

Page 162

†1] In the manuscript he writes ξ instead of x , cf. above, §125.

†1] W. had just written in the manuscript: One is constantly confused by the thought 'but can there be a possibility without a corresponding reality?'

†1] The only reason why you can't say there are infinitely many things is that there aren't. If there were, you could also express the fact I [Manuscript]

†1] (Later marginal note): Act of *decision*, not *insight*.

†2] This sentence is incomplete in the manuscript. [ed.]

†1] In this connection, W. had written in the manuscript:

I still haven't stressed sufficiently that $25 \times 25 = 625$ is on *precisely* the same level as and of *precisely the same kind* as $x^2 + y^2 + 2xy = (x + y)^2$

In the case of general propositions, what corresponds to the proposition $25^2 \neq 620$? It would be $\sim(x, y)(x + y)^2 = x^2 + y^2$, or in words, it is not a rule that ' $(x + y)^2 = x^2 + y^2$ ', or more precisely, the two sides of this equation--taken in the way the '(x)' indicates--are not equal to one another.'

But this sign '(x)' says exactly the opposite of what it says in non-mathematical cases... i.e. precisely that we should treat the variables in the proposition as constants. You could paraphrase the above proposition by saying 'It isn't correct--if we treat x and y as constants--that $(x + y)^2 = x^2 + y^2$ '.....

$(a + b)^2 = a^2 + 2ab + b^2$ yields $x = 2$

$(x + b)^2 = x^2 + 2xb + b^2$ yields $x = x$ } and refer to the same state of affairs which is also affirmed by $(a + b)^2 = a^2 + 2ab + b^2$. (But is that true?)'

And *after* the remark given in the text: 'But what is meant by knowing the rules for calculating?'

†1] Cf. below p. 178.

†1] By this point in his manuscript Wittgenstein had already written the paragraph in §189: 'I say that the so-called "Fermat's last Theorem"†1 is no kind of *proposition*†1 (not even in the sense of a proposition of arithmetic). It would, rather, correspond to a proof by induction. But if, now, there is a number $F = 0.110000$ etc. and the proof succeeds, then it would surely give us a proof that $F = 0.11$ and surely that's a proposition! Or: it's a proposition in the case of the law F being a number.'

†1 Satz.

†1] Manuscript (a bit earlier): 'Whatever one can tackle is a problem. (So mathematics is all right.)' [In English]

†1] Earlier in the manuscript W. had distinguished 'the real mathematical proposition' (i.e. the proof) from 'the so-called mathematical proposition' (existing without its proof), e.g. in the following context:

'What sort of a proposition is "there is a prime number between 5 and 8"? I would say: "That *shows* itself". And that is correct; but can't we draw attention to this internal state of affairs?...

... I can, e.g., write the number 5 in such a way that you can clearly see that it's only divisible by 1 and itself:...

Perhaps this comes down to the same thing as what I meant earlier when I said that the real mathematical proposition is a proof of a so-called mathematical proposition. The real mathematical proposition is the proof: that is to say, the thing which shows how matters stand.'

Page 186

†1] See above p. 132. [ed.]

Page 186

†2] In the sense in which you write history. [ed.]

Page 194

†1] This remark refers to the first section of Th. Skolem's *Begründung der Elementaren Arithmetik durch die Rekurrerende Denkweise ohne Anwendung Scheinbarer Veränderlichen mit Unendlichem Ausdehnungsbereich* (Videnskapsselskapets Skrifter. 1 Math.-Naturv. Klasse 1923, No. 6.). [Translated in van Heijenoort: *From Frege to Gödel*, Harvard University Press, 1967, pp. 302-333.]

Page 194

The text runs:

§1 Addition

Page 194

I will introduce a descriptive function of two variables a and b , which I will designate by means of $a + b$ and call the sum of a and b , in that, for $b = 1$, it is to mean simply the successor of a , $a + 1$. And so this function is to be regarded as already defined for $b = 1$ and arbitrary a . In order to define it in general, I in that case only need to define it for $b + 1$ and arbitrary a , on the assumption that it is already defined for b and arbitrary a . This is done by means of the following definition:

Page 194

Def. 1. $a + (b + 1) = (a + b) + 1$

Page 194

In this manner, the sum of a and $b + 1$ is equated with the successor of $a + b$. And so if addition is already defined for arbitrary values of a for a certain number b , then by Def. 1 addition is explained for $b + 1$ for arbitrary a , and

Footnote Page Break 195

thereby is defined in general. This is a typical example of a recursive definition.

Page 195

Theorem 1. The associative law: $a + (b + c) = (a + b) + c$.

Page 195

Proof: The theorem holds for $c = 1$ in virtue of Def. 1. Assume that it is valid for a certain c for arbitrary a and b .

Page 195

Then we must have, for arbitrary values of a and b

$$(\alpha) \quad a + (b + (c + 1)) = a + ((b + c) + 1)$$

since, that is to say, by Def. 1 $b + (c + 1) = (b + c) + 1$. But also by Def. 1

$$(\beta) \quad a + ((b + c) + 1) = (a + (b + c)) + 1.$$

Now, by hypothesis, $a + (b + c) = (a + b) + c$, whence

$$(\gamma) \quad (a + (b + c)) + 1 = ((a + b) + c) + 1.$$

Finally, by Def. 1 we also have

$$(\delta) \quad ((a + b) + c) + 1 = (a + b) + (c + 1).$$

From (α) , (β) , (γ) , and (δ) there follows

$$a + (b + (c + 1)) = (a + b) + (c + 1),$$

whence the theorem is proved for $c + 1$ with a and b left undetermined. Thus the theorem holds generally. This is a typical example of a recursive proof (proof by complete induction).

Page 194

In the margin of his copy, Wittgenstein drew arrows pointing to 'Theorem 1' and to (α) and wrote: 'the c is a different kind of variable in these two cases'. He puts a question mark against the equals sign in (γ) ; and another

question mark and 'Transition?' against the words 'whence the theorem is proved for $c + 1$ with a and b left undetermined'. Cf. above footnote on p. 144: 'If one makes the wrong transition from a variable proposition to a general proposition....'

Page 198

$$\dagger 1] a + (b + c) = (a + b) + c.$$

Page 198

$$\dagger 2] a + (b + 1) \stackrel{\text{Def}}{=} (a + b) + 1.$$

Page 204

$\dagger 1]$ Fundamental Theorem = Hauptsatz, proposition = Satz. [trans.]

Page 210

$\dagger 1]$ In the notebook W. then wrote: 'Strangely enough the general concept of the ancestral relation also seems to me to be nonsense now. It seems to me that the variable n must always be confined as lying within two limits.'

Page 210

$\dagger 2]$ 'If it were admissible to write ' $(\exists nx) \cdot \phi x$ ' instead of ' $(\exists x) \cdot \phi x$ ', then it would be admissible to write ' $(nx) \cdot \phi x$ ' instead of ' $\sim(\exists x) \sim \phi x$ '--and so of ' $(x) \cdot \phi x$ '--and that presupposes that there are infinitely many objects.

Page 210

And so the $(\exists nx)...$, if it has any justification at all, here may not mean 'there is one among all the numbers...'

[Manuscript]

Page 220

$\dagger 1]$ (Later gloss): This isn't true! The process of measuring! Nothing determines what the outcome of the process of bisection is going to be.

Page 222

$\dagger 1]$ In this, and the following paragraphs: rule = Vorschrift (prescription). [trans.]

Page 222

$\dagger 2]$ In Russell's sense of type. [trans.]

Page 224

$\dagger 1]$ This sign is to express the prescription: write out the digits of $\sqrt{2}$: but whenever a 5 occurs in $\sqrt{2}$, substitute a 3 for it. Wittgenstein also writes this prescription in the form $\sqrt[4]{\sqrt{2} \cdot \sqrt{2}}$ means: $\sqrt{2}$ expanded to 4 places in a given

Footnote Page Break 225

system--say the decimal system. Sometimes he also writes $\overset{7 \rightarrow 3}{\pi}$, or π' , and that means: write out the decimal expansion of π , but whenever a 7 occurs, substitute a 3 for it. " $\overset{\pi}{4}$ " would mean: π expanded to 4 places (e.g. in the decimal system). Thus $\overset{\pi}{1}$ would be 3, $\overset{\pi}{2}$, 3.1 in the decimal system.

Page 226

$\dagger 1]$ Cf. for example what A. Fränkel says about Cantor's "diagonal number": "... for whilst in general, for every k , δ_k is to be set equal to 1, this rule is subject to an exception solely for those values of k for which the digit 1 is already in the relevant diagonal place of Φ , i.e. at the position of the k th digit of the k th decimal fraction; for such, and only for such, values of k , δ_k is to be set equal to 2." *Einleitung in die Mengenlehre*, 3rd ed. 1928, p. 47. [ed.]

Page 232

$\dagger 1]$ Theorem, proposition = Satz. [trans.]

Page 237

$\dagger 1]$ Cf. The opening sentence of §189 (p. 232 above), and below p. 240.

Page 238

$\dagger 1]$ (Manuscript): What about an operation such as $x)(y$; we form the product of x and y ; if it is greater than 100, the result is the greater of the two numbers, otherwise it is 0?

Page 238

12)(10 = 12. The operation isn't arithmetically comprehensible.

Page 239

$\dagger 1]$ The words 'of the summation' have been added in the translation to make clearer Wittgenstein's meaning in this highly compressed paragraph: we take the 'stages' referred to in the original as referring to the stages in some method of computing e , and for what Wittgenstein says here to be true, he must have in mind a method such as the summing of the usual series for e , which produces a monotone increasing series of approximations. [trans.]

†2] Similar to the above: 'Is 3.14 the circumference of a unit circle? No, it's the perimeter of a ----gon.'

[Manuscript]

†1] (Manuscript): I once asked: 'How can I call a law which represents the endless nesting of intervals anything but a number?'--But why do I term such a nesting a number?--Because we can significantly say that every number lies to the left or right of this nesting.

†1] Nicod, *The Foundations of Geometry and Induction*.

†1] Throughout this section we have translated 'verschwommen' by either 'vague' or 'blurred' for purely stylistic reasons. [trans.]

†1] As Wittgenstein has written these two propositions, the word 'equal' doesn't occur; but this hardly matters.

†2] In the first chapter of *Analysis of Sensations*, p. 19.

†1] Cf. below, p. 285. [ed.]

†1] Francis Galton, *Inquiries into Human Faculty*, London, 1883, Ch. 1 and Appendix A on 'Composite portraiture'.

†1] In the manuscript, Wittgenstein writes this sentence in the form, 'Die beobachtete Verteilung von Ereignissen kann mich zu dieser Annahme führen.' ['The observed distribution of events can lead me to this assumption.'] In the typescript the 'mich' is changed to 'nicht'; this is the reading given in

the German text and which we have followed. It is possible that the typescript reading is a misprint, but it does seem to make neatest sense in the context, provided one allows the slightly strained way of taking 'kann nicht', ['The observed distribution of events cannot lead to this assumption' appears not to fit the context at all.] [trans.]

†* The following translations have been used throughout this discussion: *Tat*, act; *Tatsache*, fact; *Ereignis*, event; *hinweisen auf*, point out; *zeigen auf*, point at. The one nuance it seems impossible to pick up in English is the link between '*Diese Tatsache besteht*' = 'this fact obtains' and '*Dieser Komplex besteht aus...*' = 'this complex is composed of'; we have rendered the noun from *bestehen*, '*Bestandteil*', 'component part'; in translations of the *Tractatus* and other related discussions these last two are usually rendered 'consists of', 'constituent' (as Wittgenstein indicates in the last paragraph). [trans.]

†1] Cf. §145, p. 165, 166.

†1] See p. 166.

†2] In the Manuscript, this sentence immediately follows the paragraph about the red spheres.

†1] An apparent reference to a remark of H. Hahn.

†1] Cf. §142, p. 162.

†1] Cf. §147, p. 169; §212, p. 265.

†1] Cf. §139, p. 159; §144, p. 164.

†1] 'Die Idee des Widerspruchs ist die Kontradiktion'. The use of the ordinary German word for contradiction and the (practically synonymous) loan-word gives to this sentence overtones difficult to reproduce in English. The main point of the remark seems to be 'Look, by a contradiction we must mean a *contradiction*' (Everything's what it is and not another thing), where he goes on to spell out what is involved in the notion of contradiction, and what can

be overlooked in talking of contradictions within calculi. But there are additional overtones introduced by the fact that the word *Kontradiktion* is the word used in the *Tractatus* as the converse of *Tautologie*. It would produce artificialities to translate *Widerspruch* and *Kontradiktion* by different words: in most contexts Wittgenstein uses them virtually interchangeably. Where this has seemed the most natural rendering (as in 'consistency proof') we have translated 'Widerspruch' by 'inconsistency'. We think that the force of Wittgenstein's remarks comes over clearly enough to render clumsy and unnecessary the use of different standard translations for the two words. [trans.]

CONTENTS

Part I: The Proposition and its Sense

Page 5

I

Page 5

- 1 How can one talk about "understanding" and "not understanding" a proposition?
Surely it's not a proposition until it's understood? 39

Page 5

- 2 Understanding and signs. Frege against the formalists. Understanding like seeing a picture that makes all the rules clear; in that case the picture is itself a sign, a calculus.
"To understand a language"--to take in a symbolism as a whole.
Language must speak for itself. 39

Page 5

- 3 One can say that meaning drops out of language.
In contrast: "Did you mean that seriously or as a joke?"
When we *mean* (and don't just say) words it seems to us as if there were something coupled to the words.
41

Page 5

- 4 Comparison with understanding a piece of music: for explanation I can only translate the musical picture into a picture in another medium--and why just *that* picture? Comparison with understanding a picture. Perhaps we see only patches and lines--"we do not understand the picture". Seeing a genre-picture in different ways.
41

Page 5

- 5 "I understand that gesture"--it says something.
In a sentence a word can be felt as belonging first with one word and then with another.
A 'proposition' may be what is conceived in different ways or the way of conceiving itself.

Page Break 6

A sentence from the middle of a story I have not read.
The concept of understanding is a fluid one. 42

Page 6

- 6 A sentence in a code: at what moment of translating does understanding begin?
The words of a sentence are arbitrary; so I replace them with letters. But now I cannot immediately think the sense of the sentence in the new expression.
The notion that we can only imperfectly *exhibit* our understanding; the expression of understanding has something missing that is *essentially* inexpressible. But in that case it makes no sense to speak of a more complete expression. 43

Page 6

- 7 What is the criterion for an expression's being meant *thus*? A question about the relationship between two linguistic expressions. Sometimes a translation into another mode of representation. 45

Page 6

- 8 Must I understand a sentence to be able to act on it? If "to understand a sentence" means somehow or other to act on it, then understanding cannot be a precondition for our acting on it.--What goes on when I suddenly understand someone else? There are *many* possibilities here. 45

Page 6

- 9 Isn't there a gap between an order and its execution? "I understand it, but only because I add something to it,

namely the interpretation."--But if one were to say "any sentence still stands in need of an interpretation", that would mean: no sentence can be understood without a rider. 46

Page 6

10 "Understanding a word"--*being able* to apply it.--"When I said 'I can play chess' I really could." How did I know that I could? My answer will show in what way I use the word "can".

Being able is called a *state*. "To describe a state" can mean various things. "After all I can't have the whole mode of application of a word in my head all at once." 47

Page Break 7

Page 7

11 It is not a question of an instantaneous grasping.--

When a man who knows the game watches a game of chess, the experience he has when a move is made usually differs from that of someone else watching without understanding the game. But this experience is not the knowledge of the rules.--The understanding of language seems like a background; like the *ability* to multiply.

Page 7

12 *When* do we understand a sentence?--When we've uttered the whole of it? Or while uttering it?

50

Page 7

13 When someone interprets, or understands, a sign in one sense or another, what he is doing is taking a step in a calculus.--"Thought" sometimes means a process which may accompany the utterance of a sentence and sometimes the sentence itself in the system of language. 50

Page 7

II

14 Grammar as (e.g.) the geometry of negation. We would like to say: "Negation has the property that when it is doubled it yields an affirmation". But the rule doesn't give a further description of negation, it constitutes negation. 52

Page 7

15 Geometry no more speaks about cubes than logic does about negation.

It looks as if one could *infer* from the meaning of negation that " $\sim\sim p$ " means p . 52

Page 7

16 What does it mean to say that the "is" in "The rose is red" has a different meaning from the "is" in "twice two is four"? Here we have *one* word but as it were different *meaning-bodies* with a single end surface: different possibilities of constructing sentences. The comparison of the glass cubes. The rule for the arrangement of the red sides contains the possibilities, i.e. the geometry of the cube. The cube can also serve as a notation for the rule if it belongs to a system of propositions. 53

Page Break 8

Page 8

17 "The grammatical possibilities of the negation-sign". The T-F notation can illustrate the meaning of "not". The written symbol becomes a sign for negation only by the way it *works*--the way it is used in the game. 55

55

Page 8

18 If we derive geometrical propositions from a drawing or a model, then the model has the role of a sign in a game. We use the drawing of a cube again and again in different contexts. It is this *sign* that we take to be the cube in which the geometrical laws are already laid up. 55

55

Page 8

19 My earlier concept of meaning originates in a primitive philosophy of language.--Augustine on the learning of language. He describes a calculus of our language, only not everything that we call language is this calculus. 56

56

Page 8

20 As if words didn't also have functions quite different from the naming of tables, chairs, etc.--Here is the origin of the bad expression: a fact is a complex of objects. 57

57

Page 8

21 In a familiar language we experience different parts of speech as different. It is only in a foreign language that we see clearly the uniformity of words. 58

58

Page 8

22 If I decide to use a new word instead of "red", how would it come out that it took the place of the word "red"?

23 The meaning of a word: what the explanation of its meaning explains. (If, on the other hand by "meaning" we mean a characteristic sensation, then the explanation of meaning would be a cause.) 59

24 Explanation can clear up misunderstandings. In that case understanding is a correlate of explanation.--Definitions.

It seems as if the other grammatical rules for a word had to follow from its ostensive definition. But is this definition really unambiguous? One must understand a great deal of a language in order to understand the definition. 60

25 The words "shape", "colour" in the definitions determine the *kind of use* of the word. The ostensive definition has a different role in the grammar of each part of speech. 61

26 So how does it come about that on the strength of this definition we understand the word?

What's the sign of someone's understanding a game? Can't he learn a game simply by watching it being played? Learning and speaking without explicit rules. We are always *comparing* language with a game according to rules. 61

27 The names I give to bodies, shapes, colours, lengths have different grammars in each case. The meaning of a name is not the thing we point to when we give an ostensive definition of the name. 63

28 What constitutes the meaning of a word like "perhaps"?

I know how it is used. The case is similar when someone is explaining to me a calculation "that I don't quite understand". "Now I know how to go on." How do I know that I know how to go on? 64

29 Is the meaning really only the use of the word? Isn't it the way this use meshes with our life? 65

30 The words "fine", "oh", "perhaps"... can each be the expression of a feeling. But I don't call that feeling the meaning of the word.

I can replace the sensations by intonation and gestures.

I could also treat the word (e.g. "oh") itself as a gesture. 66

31 A language spoken in a uniform metre.

Relationships between tools in a toolbox.

"The meaning of a word: its role in the calculus of language." Imagine how we calculate with "red". And then: the word "oh"--what corresponds now to the calculus? 67

32 Describing ball-games. Perhaps one will be unwilling to call some of them ball-games; but it is clear where the boundary is to be drawn here?

We consider language from one point of view only.

The explanation of the purpose or the effect of a word is not what we call the explanation of its meaning. It may be that if it is to achieve its effect a particular word cannot be replaced by any other, just as it may be that a gesture cannot be replaced by any other.--We only bother about what's called the explanation of meaning and not about meaning in any other sense. 68

33 Aren't our sentences parts of a mechanism? As in a pianola? But suppose it is in bad condition? So it is not the effect but the purpose that is the sense of the signs (the holes in the pianola roll). Their purpose *within* the mechanism.

We need an explanation that is *part of the calculus*.

"A symbol is something that produces this effect."--How do I know that it is *the one I meant*?"

We could use a colour-chart: and then our calculus would have to get along with the visible colour-sample.

69

Page 10

34 "We could understand a penholder too, if we had given it a meaning." Does the understanding contain the whole system of its application?

Page Break 11

When I read a sentence with understanding something happens: perhaps a picture comes into my mind. But before we call "understanding" is related to countless things that happen before and after the reading of *this* sentence.

When I don't understand a sentence--that can be different things in different cases.

"Understanding a word"--that is infinitely various. 71

Page 11

35 "Understanding" is not the name of a single process but of more or less interrelated processes against a background of the actual use of a learnt language.--We think that if I use the word "understanding" in all these cases there must be some one thing that happens in all of them. Well, the concept-word certainly does show a kinship but this need not be the sharing of a common property or constituent.--The concept-word "game". "By 'knowledge' we mean these processes, and these, and *similar ones*." 74

Page 11

III

36 If for our purposes we wish to regulate the use of a word by definite rules, then alongside its fluctuating use we set a different use. But this isn't like the way physics gives a simplified description of a natural phenomenon. It is not as if we were saying something that would hold only of an ideal language. 77

Page 11

37 We understand a genre-picture if we recognize what the people in it are doing. If this recognition does not come easily, there is a period of doubt followed by a familiar process of recognition. If on the other hand we take it in at first glance it is difficult to say what the understanding--the recognition say--consists of. There is no one thing that happens that could be called recognition.

If I want to say "I understand it *like that*" then the "*like that*" stands for a translation into a different expression. Or is it a sort of intransitive understanding? 77

Page Break 12

Page 12

38 Forgetting the meaning of a word. Different cases. The man feels, as he looks at blue objects, that the connection between the word "blue" and the colour has been broken off. We might restore the connection in various ways. The connection is not made by a single phenomenon, but can manifest itself in very various processes. Do I mean then that there is no such thing as understanding but only manifestations of understanding?--a senseless question. 79

Page 12

39 How does an ostensive definition work? Is it put to work again every time the word is used? Definition as a part of the calculus acts only by being applied. 80

Page 12

40 In what cases shall we say that the man understands the word "blue"? In what circumstances will *he* be able to say it? or to say that he understood it in the past?

If he says "I picked the ball out by guesswork, I didn't understand the word", ought we to believe him? "He can't be wrong if he says that he didn't understand the word": a remark on the grammar of the statement "I didn't understand the word". 81

Page 12

41 We call understanding a mental state, and characterize it as a *hypothetical* process. Comparison between the grammar of mental processes and the grammar of brain processes.

In certain circumstances both our picking out a red object from others on demand and our being able to give the ostensive definition of the word "red" are regarded as signs of understanding.

We aren't interested here in the difference between thinking out loud (or in writing) and thinking in the imagination.

What we call "understanding" is not the behaviour that shows us the understanding, but a state of which this behaviour is a sign. 82

Page Break 13

42 We might call the recital of the rules on its own a criterion of understanding, or alternatively tests of use on their own. Or we may regard the recital of the rules as a symptom of the man's being able to do something other than recite the rules.

To understand = to let a proposition work on one.

When one remembers the meaning of a word, the remembering is not the mental process that one imagines at first sight.

The psychological process of understanding is in the same case as the arithmetical object Three.

84

43 An explanation, a chart, is first used by being looked up, then by being looked up in the head, and finally as if it had never existed.

A rule as the cause or history behind our present behaviour is of no interest to us. But a rule can be a hypothesis, or can itself enter into the conduct of the game. If a disposition is hypothesized in the player to give the list of rules on request, it is a disposition analogous to a physiological one. In our study of symbolism there is no foreground and background.

85

44 What interests *us* in the sign is what is embodied in the grammar of the sign. 87

IV

45 The ostensive definition of signs is not an *application* of language, but part of the grammar: something like a rule for translation from a gesture language into a word-language.--What belongs to grammar are all the conditions necessary for comparing the proposition with reality--all the conditions necessary for its sense.

88

46 Does our language consist of primary signs (gestures) and secondary signs (words)?

Obviously we would not be able to replace an ordinary sentence by gestures.

"Is it an accident that in order to define the signs I have to go outside the written and spoken signs?" In that case isn't it strange that I can do anything at all with the written signs? 88

47 We say that a red label is the primary sign for the colour red, and the word a secondary sign.--But must a Frenchman have a red image present to his mind when he understands my explanation "red = rouge"?

89

48 Are the primary signs incapable of being misinterpreted? Can one say they don't any longer need to be *understood*?

90

49 A colour chart might be arranged differently or used differently, and yet the words mean the same colours as with us.

Can a green label be a *sample* of red?

Can it be said that when someone is painting a certain shade of green he is *copying* the red of a label?

A sample is not used like a name.

90

50 "Copy" can mean various things. Various methods of comparison.

We do not understand what is meant by "this shade of colour is a copy of this note on the violin." It makes no sense to speak of a projection-method for association.

91

51 We can say that we communicate by signs whether we use words or samples, but the game of acting in accordance with words is different from the game of acting in accordance with samples.

92

52 "There must be some sort of law for reading the chart.--Otherwise *how would one know* how the table was to be used?" It is part of human nature to understand pointing with the finger in the way we do.

The chart does not compel me to use it always in the same way. 93

53 Is the word "red" enough to enable one to look for something red? Does one need a memory image to do so?

An order. Is the real order "Do now what you remember doing then?"

If the colour sample appears darker than I remember it being yesterday, I need not agree with my memory.

94

54 "Paint from memory the colour of the door of your room" is no more unambiguous than "paint the green you see on this chart."

I see the colour of the flower and recognize *it*.

Even if I say "no, this colour is brighter than the one I saw there," there is no process of comparing two simultaneously given shades of colour.

Think of reading aloud from a written test (or writing to dictation). 95

55 "Why do you choose *this* colour when given this order?"--"Because *this* colour is opposite to the word 'red' in my chart." In that case there is no sense in *this* question: "Why do you call 'red' the colour in the chart opposite the word 'red'?"

The connection between "language and reality" is made by definitions of words--which belong to grammar.

96

56 A gesture language used to communicate with people who have no word-language in common with us. Do we feel there too the need to go outside language to explain its signs?

The correlation between objects and names is a part of the symbolism. It gives the wrong idea if you say that the connection is a psychological one. 97

57 Someone copies a figure on the scale of 1 to 10. Is the understanding of the general rule of such mapping contained in the process of copying?

Or was the process merely *in agreement with* that rule, but also in agreement with other rules?

97

58 Even if my pencil doesn't always do justice to the model, my intention always does. 98

59 For our studies it can never be essential that a symbolic phenomenon occurs in the mind and not on paper.

An explanation of a sign can replace the sign itself--this contrasts with causal explanation. 99

60 Reading.--Deriving a translation from the original may also be a visible process.

Always what represents is the system in which a sign is used.

If 'mental' processes can be true and false, their descriptions must be able to as well. 99

61 Every case of deriving an action from a command is the same kind of thing as the written derivation of a result.

"I write the number '16' here *because* it says 'x²' there."

It might appear that some causality was operating here, but that would be a confusion between 'reason' and 'cause'. 101

V

62 "That's *him*"--that contains the whole problem of representation.

I make a plan: I see myself acting thus and so. "How do I know that it's myself?" Or "How do I know that the word 'I' stands for me?"

The delusion that in thought the objects do what the proposition states about them.

"I meant the victor of Austerlitz"--the past tense, which looks as if it was giving a description, is deceptive.

102

63 "How does one think a proposition? How does thought use its expression?"

Let's compare belief with the utterance of a sentence: the processes in the larynx etc. *accompany* the spoken sentence which alone interests us--not as part of a mechanism, but as part of a calculus.

We think we can't describe thought after the event because the delicate processes have been lost sight of.

What is the function of thought? Its *effect* does not interest us. 103

Page 17

64 But if thinking consists only in writing or speaking, why shouldn't a machine do it?

Could a machine be in pain?

It is a travesty of the truth to say: thinking is an activity of our mind, as writing is an activity of the hand.

105

Page 17

65 'Thinking' 'Language' are fluid concepts.

The expression "mental process" is meant to distinguish 'experience' from 'physical processes'; or else we talk of 'unconscious thoughts'--of processes in a mind-model; or else the word "thought" is taken as synonymous with "sense of a sentence". 106

Page 17

66 The idea that one language in contrast to others can have an order of words which corresponds to the order of thinking.

Is it, as it were, a contamination of the sense that we express it in a particular language? Does it impair the rigour and purity of the proposition $25 \times 25 = 625$ that it is written down in a particular number system?

Thought can only be something common-or-garden. But we are affected by this concept as we are by that of the number one. 107

Page 17

67 What does man think for? There is no such thing as a "thought-experiment".

Page Break 18

I believe that more boilers would explode if people did not calculate when making boilers. Does it follow that there will in fact be fewer? The belief that fire will burn me is of the same nature as the fear that it will burn me.

109

Page 18

68 My assumption that this house won't collapse may be the utterance of a sentence which is part of a calculation. I do have reasons for it. *What* counts as a reason for an assumption determines a calculus.--So is the calculus something we adopt arbitrarily? No more so than the fear of fire.

As long as we remain in the province of true-false games a change of grammar can only lead us from one game to another, and never from something true to something false. 110

Page 18

VI

69 What is a proposition?--Do we have a single general concept of proposition? 112

Page 18

70 "What happens when a new proposition is taken into the language: what is the criterion for its being a *proposition*?"

In this respect the concept of number is like the concept of proposition. On the other hand the concept of cardinal number can be called a rigorously circumscribed concept, that's to say it's a concept in a different sense of the word. 113

Page 18

71 I possess the concept 'language' from the languages I have learnt. "But language can expand": if "expand" makes sense here, I must *now* be able to specify how I imagine such an expansion.

No sign leads us beyond itself.

Does every newly constructed language broaden the concept of language?--Comparison with the concept of number. 114

Page Break 19

Page 19

72 The indeterminacy of generality is not a logical indeterminacy.

The task of philosophy is not to create an ideal language, but to clarify the use of existing language.

I'm allowed to use the word "rule" without first tabulating the rules for the word.--If philosophy was concerned with the concept of the calculus of all calculi, there would be such a thing as metaphilosophy. But there is

not. 115

Page 19

73 It isn't on the strength of a particular property, the property of being a rule, that we speak of the rules of a game.--We use the word "rule" in contrast to "word", "projection" and some other words.

116

Page 19

74 We learnt the meaning of the word "plant" by examples. And if we disregard hypothetical dispositions, these examples stand only for themselves.--

The grammatical pace of the word "game" "rule" etc is given by examples in rather the way in which the place of a meeting is specified by saying that it will take place *beside* such and such a tree. 117

Page 19

75 Meaning as something which *comes before* our minds when we hear a word.

"Show the children a game".

The sentence "The Assyrians knew various games" would strike us as curious since we wouldn't be certain that we could give an example. 118

Page 19

76 Examples of the use of the word "wish". Our aim is not to give a theory of wishing, which would have to explain every case of wishing.

The use of the words "proposition", "language", etc. has the haziness of the normal use of concept-words in our language. 119

Page 19

77 The philosophy of logic speaks of sentences and words in the sense in which we speak of them in ordinary life.

Page Break 20

(We are not justified in having any more scruples about our language than the chess player has about chess, namely none.) 121

Page 20

78 Sounding like a sentence. We don't call everything 'that sounds like a sentence' a sentence.--If we disregard sounding like a sentence do we still have a general concept of proposition?

The example of a language in which the order of the words in a sentence is the reverse of the present one.

122

Page 20

79 The definition "A proposition is whatever can be true or false".--The words "true" and "false" are items in a particular notation for the truth-functions.

Does "p' is true" state anything about the sign 'p'? 123

Page 20

80 In the schema "This is how things stand" the "how things stand" is a handle for the truth-functions.

A general propositional form determines a proposition as part of a calculus. 124

Page 20

81 The rules that say that such and such a combination of words yields no sense.

"How do I know that red can't be cut into bits?" is not a question. I must *begin* with the distinction between sense and nonsense. I can't give it a foundation. 125

Page 20

82 "How must we make the grammatical rules for words if they are to give a sentence sense?"--

A proposition shows the possibility of the state of affairs it describes. "Possible" here means the same as "conceivable"; representable in a particular system of propositions.

The proposition "I can imagine such and such a colour transition connects the linguistic representation with another form of representation; it is a proposition of grammar. 127

Page 20

83 It looks as if we could say: Word-language allows of senseless combinations of words, but the language of imagining does not allow us to imagine anything senseless.

Page Break 21

"Can you imagine it's being otherwise?"--How strange that one should be able to say that such and such a state of affairs is inconceivable! 128

Page 21

84 The role of a proposition in the calculus is its sense.

It is only in language that something is a proposition. To understand a proposition is to understand a language. 130

Page 21

VII

85 Symbols appear to be of their nature unsatisfied.

A proposition seems to demand that reality be compared with it.

"A proposition like a ruler laid against reality." 132

Page 21

86 If you see the expression of an expectation you see what is being expected.

It looks as if the ultimate thing sought by an order had to remain unexpressed.--As if the sign was trying to communicate with us.

A sign does its job only in a grammatical system. 132

Page 21

87 It seems as if the expectation and the fact satisfying the expectation fitted together somehow. Solids and hollows.--Expectation is not related to its satisfaction in the same way as hunger is related to its satisfaction.

133

Page 21

88 The strange thing that the event I expected isn't distinct from the one I expected.--"The report was not so loud as I had expected."

"How can you say that the red which you see in front of you is the same as the red you imagined?"--One takes the meaning of the word "red" as being the sense of a proposition saying that something is red.

134

Page 21

89 A red patch looks different from one that is not red. But it would be odd to say "a red patch looks different when it is there from when it isn't there". Or: "How do you know that you are expecting a *red* patch?"

135

Page Break 22

Page 22

90 How can I expect the event, when it isn't yet there at all?--I can imagine a stag that is not there, in this meadow, but not kill one that is not there.--It is not the expected thing that is the fulfilment, but rather its coming about. It is difficult for us to shake off this comparison: a man makes his appearance--an event makes its appearance. 136

Page 22

91 A search for a particular thing (e.g. my stick) is a particular kind of search, and differs from a search for something else because of what one does (says, thinks) while searching, not because of what one finds.--Contrast looking for the trisection of the angle. 138

Page 22

92 The symptoms of expectation are not the expression of expectation.

In the sentence "I expect that he is coming" is one using the words "he is coming" in a different sense from the one they have in the assertion "he is coming"?

What makes it the expectation precisely of *him*?

Various definitions of "expecting a person X".

It isn't a later experience that decides *what* we are expecting.

"Let us put the expression of expectation in place of the expectation." 138

Page 22

93 Expectation as preparatory behaviour.

"Expectation is a thought"

If *hunger* is called a wish it is a hypothesis that just that will satisfy the wish.

In "I have been expecting him all day" "expect" does not mean a persistent condition. 140

Page 22

94 When I expect someone,--what happens?

What does the process of wanting to eat an apple consist in? 141

Page Break 23

Page 23

95 Intention and intentionality.--

"The thought that p is the case doesn't presuppose that it is the case; yet I can't think that something is red if

the colour red does not exist." Here we mean the existence of a red sample *as part of our language*.

142

Page 23

96 It's beginning to look somehow as if intention could never be recognized as *intention* from the outside. But the point is that one has to read off from a thought that it is the thought that such and such is the case.

143

Page 23

97 This is connected with the question whether a machine could think. This is like when we say: "The will can't be a phenomenon, for whatever phenomenon you take is something that *simply happens*, not something we *do*." But there's no doubt that you *also* have experiences when you move your arm voluntarily, although the phenomena of doing are indeed different from the phenomena of observing. But there are very different cases here.

144

Page 23

98 The intention seems to interpret, to give the final interpretation.

Imagine an 'abstract' sign-language translated into an unambiguous picture-language. Here there seem to be no further possibilities of interpretation.--We might say we didn't enter into the sign-language but did enter into the painted picture. Examples: picture, cinema, dream.

145

Page 23

99 What happens is not that this symbol cannot be further interpreted, but: I do no interpreting.

I imagine N. No interpretation accompanies this image; what gives the image its interpretation is the *path* on which it lies.

147

Page 23

100 We want to say: "Meaning is essentially a mental process, not a process in dead matter."--What we are dissatisfied with here is the grammar of *process*, not the specific kind of process.

148

Page Break 24

Page 24

101 Doesn't the system of language provide me with a medium in which the proposition is no longer dead?--"Even if the *expression* of the wish is the wish, still the whole language isn't present during this expression." But that is not necessary.

149

Page 24

102 In the gesture we don't see the real shadow of the fulfilment, the unambiguous shadow that admits of no further interpretation.

149

Page 24

103 It's only considering the linguistic manifestation of a wish that makes it appear that my wish prefigures the fulfilment.--Because it's the wish that just that were the case.--It is in language that wish and fulfilment meet.

150

Page 24

104 "A proposition isn't a mere series of sounds, it is something more." Don't I see a sentence as part of a system of consequences?

152

Page 24

105 "This queer thing, thought."--It strikes us as queer when we say that it connects objects in the mind.--We're all ready to pass from it to the reality.--"How was it possible for thought to deal with the very person *himself*?" Here I am being astonished by my own linguistic expression and momentarily misunderstanding it.

154

Page 24

106 "When I think of what will happen tomorrow I am mentally already in the future."--Similarly people think that the *endless series of cardinal numbers* is somehow before our mind's eye, whenever we can use that expression significantly.

A thought experiment is like a drawing of an experiment that is not carried out. 155

Page 24

107 We said "one cannot recognize intention as intention from the outside"--i.e. that it is not something that happens, or happens to us, but something we do. It is almost as if we said: we cannot see ourselves going to a place, because it is we who are doing the going. One does have a particular experience if one is doing the going oneself.

156

Page Break 25

108 Fulfilment of expectation doesn't consist in some third thing's happening, such as a feeling of satisfaction.

157

VIII

109 A description of language must achieve the same result as language itself.

Suppose someone says that one can infer from a proposition [[sic]] the fact that verifies it. What can one infer from a proposition apart from *itself*?

The shadowy anticipation of a fact consists in our being able already to think that *that very thing* will happen which *hasn't yet* happened.

159

110 However many steps I insert between the thought and its application, each intermediate step always follows the previous one without any intermediate link, and so too the application follows the last intermediate step.--We can't cross the bridge to the execution (of an order) until we are there.

160

111 It is the *calculus* of thought that connects with extra-mental reality. From expectation to fulfilment is a step in a calculation.

160

112 We are--as it were--surprised, not at anyone's knowing the future, but at his being able to prophesy at all (right or wrong).

161

IX

113 Is the pictorial character of thought an agreement with reality? In what sense can I say that a proposition is a picture?

163

114 The sense of a proposition and the sense of a picture. The different grammar of the expressions:

"This picture shows people at a village inn."

"This picture shows the coronation of Napoleon."

164

115 A picture's telling me something will consist in my recognizing in it objects in some sort of characteristic arrangement.--

What does "this object is familiar to me" mean?

165

116 "I see what I see." I say that because I don't want to give a name to what I see.--I want to exclude from my consideration of familiarity everything that is 'historical'.--The multiplicity of familiarity is that of feeling at home in what I see.

165

117 Understanding a genre picture: don't we recognize the painted people as people and the painted trees as trees, etc.?

A picture of a human face is a no less familiar object than the human face itself. But there is no question of recognition here.

166

118 The false concept that recognizing always consists in comparing two impressions with one another.--

"We couldn't use words at all if we didn't recognize them and the objects they denote." Have we any sort of check on this recognition?

167

119 This shape I see is not simply a shape, but is one of the shapes I know.--But it is not as if I were comparing the object with a picture set beside it, but as if the object *coincided* with the picture. I see only one thing, not two.

168

120 "This face has a quite *particular* expression." We perhaps look for words and feel that everyday language is here too crude.

169

121 That a picture tells me something consists in its own form and colours. Or it narrates something to me: it uses

words so to speak, and I am comparing the picture with a combination of linguistic forms.--That a series of signs tells me something isn't constituted by its now making this impression on me. "It's only in a language that something is a proposition."
169

Page 27

122 'Language' is languages.--Languages *are* systems.
It is units of languages that I call "propositions".
170

Page 27

123 Certainly, I read a story and don't give a hang about any system of language, any more than if it was a story in pictures. Suppose we were to say at this point "something is a picture only in a picture-language."?
171

Page 27

124 We might imagine a language in whose use the impression made on us by the signs played no part.
What I call a "proposition" is a position in the game of language.
Thinking is an activity, like calculating.
171

Page 27

125 A puzzle picture. What does it amount to to say that after the solution the picture means something to us, whereas it meant nothing before?
172

Page 27

126 The impression is one thing, and the impression's being determinate is another thing. The impression of familiarity is perhaps the characteristics of the determinacy that every strong impression has.
174

Page 27

127 Can I think away the impression of individual familiarity where it exists; and think it into a situation where it does not? The difficulty is not a psychological one. *We* have not *determined* what that is to mean.
Can I look at a printed English word and see it as if I hadn't learnt to read?
I can ascribe meaning to a meaningless shape.
175

Page Break 28

Page 28

128 We can read courage into a face and say "now once more courage *fits* this face". This is related to "an attributive adjective agrees with the subject".
What do I do if I take a smile now as a kind one, now as malicious? This is connected with the contrast between *saying* and *meaning*.
176

Page 28

129 A friendly mouth, friendly eyes, the wagging of a dog's tail are primary symbols of friendliness: they are parts of the phenomena that are called friendliness. If we want to imagine further appearances as expressions of friendliness, we read these symbols into them. It is not that I can imagine that this man's face might change so that it looked courageous, but that there is a quite definite way in which it can change into a courageous face.
Think of the multifariousness of what we call "language": word-language, picture-language, gesture-language, sound-language.
178

Page 28

130 "'This object is familiar to me' is like saying 'this object is portrayed in my catalogue.'" We are making the assumption that the picture in our catalogue is itself familiar.
The sheath in my mind as a "form of imagining".--The pattern is no longer presented as an object, which means that it didn't make sense to talk of a pattern at all.
"Familiarity: an object's fitting into a sheath"--that's not quite the same as our *comparing* what is seen with a copy.
The question is "*What* do I recognize *as what*?" For "to recognize a thing as itself" is meaningless.
179

Page 28

131 The comparison between memory and a notebook.
How did I read off from the memory image that I stood thus at the window *yesterday*? What made you so certain when you spoke those words? Nothing; I *was* certain.
How do I *react* to a memory?
181

Page 28

132 Operating with written signs and operating with "imagination pictures".

An attitude to a picture (to a thought) is what connects it with reality. 182

X

133 Grammatical rules determine a meaning and are not answerable to any meaning that they could contradict.

Why don't I call cookery rules arbitrary, and why am I tempted to call the rules of grammar arbitrary?

I don't call an argument good just because it has the consequences I want.

The rules of grammar are arbitrary in the same sense as the choice of a unit of measurement.

184

134 Doesn't grammar put the primary colours together because there is a kind of similarity between them? Or colours, anyway, in contrast to shapes or notes?

The rules of grammar cannot be justified by shewing that their application makes a representation agree with reality.

The analogy between grammar and games. 185

135 Language considered as a part of a psychological mechanism.

I do not use "this is the sign for sugar" in the same way as the sentence "if I press this button, I get a piece of sugar". 187

136 Suppose we compare grammar to a keyboard which I can use to direct a man by pressing different combinations of keys. What corresponds in this case to the grammar of language?

If the utterance of a 'nonsensical' combination of words has the effect that the other person stares at me, I don't on that account call it the order to stare. 188

137 Language is not defined for us as an arrangement fulfilling a definite purpose. 189

138 Grammar consists of conventions--say in a chart. This might be a part of a mechanism. But it is the connection and not the effect which determines the meaning.

Can one speak of a grammar in the case where a language is taught to a person by a mere drill?

190

139 I do not scruple to *invent* causal connections in the mechanism of language.

To invent a keyboard might mean to invent something that had the desired effect; or else to devise new forms which were similar to the old ones in various ways.

"It is always for living beings that signs exist." 191

140 Inventing a language--inventing an instrument--inventing a game.

If we imagine a goal for chess--say entertainment--then the rules are not arbitrary. So too for the choice of a unit of measurement.

We can't say "without language we couldn't communicate with one another". The concept of language is *contained in* the concept of communication. 192

141 Philosophy is philosophical problems. Their common element extends as far as the common element in different regions of our language.

Something that at first sight looks like a proposition and is not one. Something that looks like a design for a steamroller and is not one. 193

142 Are we willing to call a series of independent signals "a language"?

Imagine a diary kept with signals. Are explanations given so that the signals are connected to another language?

A language consisting of commands. We wouldn't say that a series of such signals alone would enable me to *derive* a picture of the movement of a man obeying them unless in addition to the signal there is something that

might be called a general rule for translating into drawing.

The grammar explains the meaning of the signs and thus makes the language pictorial. 194

Page Break 37

Part I: The Proposition and its Sense

Page 37

Page Break 38

Page Break 39

I

Page 39

1 How can one talk about 'understanding' and 'not understanding' a proposition? Surely it is not a proposition until it's understood?

Page 39

Does it make sense to point to a clump of trees and ask "Do you understand what this clump of trees says?" In normal circumstances, no; but couldn't one express a sense by an arrangement of trees? Couldn't it be a code?

Page 39

One would call 'propositions' clumps of trees one understood; others, too, that one didn't understand, provided one supposed the man who planted them had understood them.

Page 39

"Doesn't understanding only start with a proposition, with a whole proposition? Can you *understand* half a proposition?"--Half a proposition is not a whole proposition.--But what the question means can perhaps be understood as follows. Suppose a knight's move in chess was always carried out by two movements of the piece, one straight and one oblique; then it could be said "In chess there are no half knight's moves" meaning: the relationship of half a knight's move to a whole knight's move is not the same as that of half a bread roll to a whole bread roll. We want to say that it is not a difference of degree.

Page 39

It is strange that science and mathematics make use of propositions, but have nothing to say about understanding those propositions.

2 We regard understanding as the essential thing, and signs as something inessential.--But in that case, why have the signs at all? If you think that it is only so as to make ourselves understood by others, then you are very likely looking on the signs as a drug which is to produce in other people the same condition as my own.

Suppose that the question is "what do you mean by that gesture?" and the answer is "I mean you must leave". The answer would not have been more correctly phrased: "I mean what I mean by the sentence 'you must leave'."

In attacking the formalist conception of arithmetic, Frege says more or less this: these petty explanations of the signs are idle once we *understand* the signs. Understanding would be something like seeing a picture from which all the rules followed, or a picture that makes them all clear. But Frege does not seem to see that such a picture would itself be another sign, or a calculus to explain the written one to us.

What we call "understanding a language" is often like the understanding we get of a calculus when we learn its history or its practical application. And there too we meet an easily surveyable symbolism instead of one that is strange to us.--Imagine that someone had originally learnt chess as a writing game, and was later shown the 'interpretation' of chess as a board game.

In this case "to understand" means something like "to take in as a whole".

If I give anyone an order I feel it to be quite enough to give him signs. And if I am given an order, I should never say: "this is only words, and I have got to get behind the words". And when I have asked someone something and he gives me an answer I am content--that was just what I expected--and I don't raise the objection: "but that's a mere answer."

But if you say: "How am I to know what he means, when I see nothing but the signs he gives?" then I say: "How is *he* to know what he means, when he has nothing but the signs either?"

What is spoken can only be explained in language, and so in this sense language itself cannot be explained.

Language must speak for itself.

3 One can say that meaning drops out of language; because what a proposition means is told by yet another proposition.

"What did you mean by those words?" "Did you *mean* those words." The first question is not a more precise specification of the second. The first is answered by a proposition replacing the proposition which wasn't understood. The second question is like: "Did you mean that seriously or as a joke?"

Compare: "Did you mean anything by that gesture--if so what?"

In certain of their applications the words "understand", "mean" refer to a psychological reaction while hearing, reading, uttering etc. a sentence. In that case understanding is the phenomenon that occurs when I hear a sentence in a familiar language and not when I hear a sentence in a strange language.

Learning a language *brings about* the understanding of it. But that belongs to the past history of the reaction.--The understanding of a sentence is as much something that happens to me as is the hearing of a sentence; it accompanies the hearing.

I can speak of 'experiencing' a sentence. "I am not merely saying this, I mean something by it." When we consider what is going on in us when we *mean* (and don't just say) words, it seems to us as if there were something coupled to the words, which otherwise would run idle. As if they *connected* with something in us.

4 Understanding a sentence is more akin to understanding a piece of music than one might think. Why must these bars be played just so? Why do I want to produce just this pattern of variation in loudness and tempo? I would like to say "Because I know what it's all about." But what is it all about? I should not be able to say. For explanation I can only translate the musical picture into a picture in another medium and let the one picture throw light on the other.

The understanding of a sentence can also be compared with what we call understanding a picture. Think of a still-life picture, and imagine that we were unable to see it as a spatial representation and saw only patches and lines on the canvas. We could say in that case "we do not understand the picture". But we say the same thing in a different sense when although we see the picture spatially we do not recognize the spatial objects as familiar things like books, animals and bottles.

Suppose the picture is a genre-picture and the people in it are about an inch long. If I had ever seen real people of that size, I would be able to recognize them in the picture and regard it as a life-size representation of them. In that case my visual experience of the picture would *not* be *the same* as the one I have when I see the picture in the normal way as a representation in miniature, although the illusion of spatial vision is the same in each case.--However, acquaintance with real inch-high people is put forward here only as one possible cause of the visual experience; except for that the experience is independent. Similarly, it may be that only someone who has already seen many real cubes can see a drawn cube spatially; but the description of the spatial visual presentation contains nothing to differentiate a real cube from a painted one.

The different experiences I have when I see a picture first one way and then another are comparable to the experience I have when I read a sentence with understanding and without understanding.

(Recall what it is like when someone reads a sentence with a mistaken intonation which prevents him from understanding it--and then realizes how it is to be read.)

(To see a watch as a watch, i.e. as a dial with hands, is like seeing Orion as a man striding across the sky.)

5 How curious: we should like to explain the understanding of a gesture as a translation into words, and the understanding of words as a translation into gestures.

And indeed we really do explain words by a gesture, and a gesture by words.

On the other hand we say "I understand that gesture" in the same sense as "I understand this theme", "it says something" and what that means is that I have a particular experience as I follow it.

Consider the difference it makes to the understanding of a sentence when a word in it is felt as belonging first with one word and then with another. I might have said: the word is conceived, understood, seen, pronounced as belonging first with one word and then with another.

We can call a 'proposition' that which is conceived first in one way and then in another; we can also mean the various ways of conceiving it. This is a source of confusions.

I read a sentence from the middle of a story: "After he had said this, he left her as he did the day before." Do I understand the sentence?--It's not altogether easy to give an answer. It is an English sentence, and to that extent I understand it. I should know how the sentence might be used, I could invent a context for it. And yet I do not understand it in the sense in which I should understand it if I had read the story. (Compare various language-games: describing a state of affairs, making up a story, etc. What counts as a significant sentence in the several cases?)

Do we *understand* Christian Morgenstern's poems, or Lewis Carroll's poem "Jabberwocky"? In these cases it's very clear that the concept of understanding is a fluid one.

6 A sentence is given me in unfamiliar code together with the key for deciphering it. Then, in a certain sense, everything required for the understanding of the sentence has been given me. And yet if I were asked whether I understood the sentence I should reply "I must first decode it" and only when I had it in front of me decoded as an English sentence, would I say "now I understand it".

If we now raise the question "At what moment of translating into English does understanding begin?" we get a glimpse into the

nature of what is called "understanding".

I say the sentence "I see a black patch there"; but the words are after all arbitrary: so I will replace them one after the other by the first six letters of the alphabet. Now it goes "a b c d e f". But now it is dear that--as one would like to say--I cannot think the sense of the above sentence straight away in the new expression. I might also put it like this: I am not used to saying "a" instead of "I", "b" instead of "see", "c" instead of "a" and so on. I don't mean that I am not used to making an immediate association between the word "I" and the sign "a"; but that I am not used to using "a" in the place of "I".

"To understand a sentence" can mean "to know what the sentence signifies"; i.e. to be able to answer the question "what does this sentence say?"

It is a prevalent notion that we can only imperfectly *exhibit* our understanding; that we can only point to it from afar or come close to it, but never lay our hands on it, and that the ultimate thing can never be said. We say: "Understanding is something *different* from the expression of understanding. *Understanding* cannot be exhibited; it is something inward and spiritual."--Or "Whatever I do to exhibit understanding, whether I repeat an explanation of a word, or carry out an order to show that I have understood it, these bits of behaviour do not *have* to be taken as proofs of understanding." Similarly, people also say "I cannot show anyone else my toothache; I cannot *prove* to anyone else that I have toothache." But the impossibility spoken of here is supposed to be a logical one. "Isn't it the case that the expression of understanding is always an incomplete expression?" That means, I suppose, an expression with something missing--but the something missing is essentially *inexpressible*, because otherwise I

might find a better expression for it. And "essentially inexpressible" means that it makes no sense to talk of a more complete expression.

The psychological processes which are found by experience to accompany sentences are of no interest to us. What does interest us is the understanding that is embodied in an explanation of the sense of the sentence.

7 To understand the grammar of the word "to mean" we must ask ourselves what is the criterion for an expression's being meant *thus*. What should be regarded as a criterion of the meaning?

An answer to the question "How is that meant?" exhibits the relationship between two linguistic expressions. So the question too is a question about that relationship.

The process we call the understanding of a sentence or of a description is sometimes a process of translation from one symbolism into another; tracing a picture, copying something, or translating into another mode of representation.

In that case understanding a description means making oneself a picture of what is described. And the process is more or less like making a drawing to match a description.

We also say: "I understand the picture exactly, I could model it in clay".

8 We speak of the understanding of a sentence as a condition of being able to apply it. We say "I cannot obey an order if I do not understand it" or "I cannot obey it before I understand it".

"Must I really understand a sentence to be able to act on it?--Certainly, otherwise you wouldn't know what you had to do."--But how does this knowing help me? Isn't there in turn a jump from knowing to doing?

Page 45

"But all the same I must understand an order to be able to act according to it"--here the "must" is fishy. If it is a logical must, then the sentence is a grammatical remark.

Page Break 46

Page 46

Here it could be asked: How long before obeying it *must* you understand the order?--But of course the proposition "I must understand the order before I can act on it" makes good sense: but not a metalogical sense.--And 'understanding' and 'meaning' are not metalogical concepts.

Page 46

If "to understand a sentence" means somehow or other to act on it, then understanding cannot be a precondition for our acting on it. But of course experience may show that the specific behaviour of understanding is a precondition for obedience to an order.

Page 46

"I cannot carry out the order because I don't understand what you mean.--Yes, I understand you now."--What went on when I suddenly understood him? Here there are *many* possibilities. For example: the order may have been given in a familiar language but with a wrong emphasis, and the right emphasis suddenly occurred to me. In that case perhaps I should say to a third party: "Now I understand him: he means..." and should repeat the order with the right emphasis. And when I grasped the familiar sentence I'd have understood the order,--I mean, I should not first have had to grasp an abstract sense.--Alternatively: I understood the order in *that* sense, so it was a correct English sentence, but it seemed preposterous. In such a case I would say: "I do not understand you: because you can't mean *that*." But then a more comprehensible interpretation occurred to me. Before I understand several interpretations, several explanations, may pass through my mind, and then I decide on one of them.

Page 46

(Understanding, when an absent-minded man at the order "Right turn!" turns left, and then, clutching his forehead, says "Oh! right turn" and does a right turn.)

Page 46

9 Suppose the order to square a series of numbers is written in the form of a table, thus:

Page Break 47

x	1	2	3
x^2			

Page 47

--It seems to us as if by understanding the order we add something to it, something that fills the gap between command and execution. So that if someone said "You understand it, don't you, so it is not incomplete" we could reply "Yes, I understand it, but only because I add something to it, namely the interpretation."--But what makes you give just *this* interpretation? Is it the order? In that case it was already unambiguous, since it demanded this interpretation. Or did you attach the interpretation arbitrarily? In that case what you understood was not the command, but only what you made of it.

Page 47

(While thinking philosophically we see problems in places where there are none. It is for philosophy to show that there are no problems.)

Page 47

But an interpretation is something that is given in signs. It is *this* interpretation as opposed to a different one (running differently). So if one were to say "Any sentence still stands in need of an interpretation" that would mean: no sentence can be understood without a rider.

Page 47

Of course sometimes I do *interpret* signs, give signs an interpretation; but that does not happen every time I understand a sign. (If someone asks me "What time is it?" there is no inner process of laborious interpretation; I simply react to what I see and hear. If someone whips out a knife at me, I do not say "I interpret that as a threat".)

Page 47

10 "Understanding a word" may mean: *knowing* how it is used; *being able to apply* it.

"Can you lift this ball?"--"Yes". Then I try and fail. Then perhaps I say "I *was wrong*, I cannot". Or perhaps "I can't now, because I am too tired; but when I said I could, I really could." Similarly "I thought I could play chess, but now I have forgotten

how", but on the other hand "When I said 'I can play chess' I really could, but now I've lost it."--But what is the criterion for my being able at that particular time? How did I know that I could? To that question I would answer "I've always been able to lift that sort of weight", "I lifted it just a moment before", "I've played chess quite recently and my memory is good", "I'd just recited the rules" and so on. What I regard as an answer to that question will show me in what way I use the word "can".

Knowing, being able to do something, a capacity is what we would call a *state*. Let us compare with each other propositions which all in various senses describe states.

"I have had toothache since yesterday."
"I have been longing for him since yesterday."
"I have been expecting him since yesterday."
"I have known since yesterday that he is coming."
"Since yesterday I can play chess."

Can one say: "I have known continuously since yesterday that he is coming?" In which of the above sentences can one sensibly insert the word "continuously"?

If knowledge is called a "state" it must be in the sense in which we speak of the state of a body or of a physical model. So it must be in a physiological sense or in the sense used in a psychology that talks about unconscious states of a mind-model. Certainly no one would object to that; but in that case one still has to be clear that we have moved from the grammatical realm of 'conscious states' into a different grammatical realm. I can no doubt speak of unconscious toothache, if the sentence "I have unconscious toothache" means something like "I have a bad tooth that doesn't ache". But the expression "conscious state" (in its old sense) doesn't have the same grammatical relationship to the expression

"unconscious state" as the expression "a chair which I see" has to "a chair which I don't see because it's behind me".

Instead of "to know something" we might say "to keep a piece of paper on which it is written".

If "to understand the meaning of a word" means to know the grammatically possible ways of applying it, then I can ask "How can I know what I mean by a word at the moment I utter it? After all, I can't have the whole mode of application of a word in my head all at once".

I can have the possible ways of applying a word in my head in the same sense as the chess player has all the rules of chess in his head, and the alphabet and the multiplication table. Knowledge is the hypothesized reservoir out of which the visible water flows.

11 So we mustn't think that when we understand or mean a word what happens is an act of instantaneous, as it were non-discursive, grasp of grammar. As if it could all be swallowed down in a single gulp.

It is as if I get tools in the toolbox of language ready for future use.

"I can use the word 'yellow'" is like "I know how to move the king in chess".

In this example of chess we can again observe the ambiguity of the word "understand". When a man who knows the game watches a game of chess, the experience he has when a move is made usually differs from that of someone else watching without understanding the game. (It differs too from that of a man who doesn't even know that it's a game.) We can also say that it's the knowledge of the rules of chess which makes the difference between the two spectators, and so too that it's the knowledge of the

Page Break 50

rules which makes the first spectator have the particular experience he has. But this experience is not the knowledge of the rules. Yet we are inclined to call them both "understanding".

Page 50

The understanding of language, as of a game, seems like a background against which a particular sentence acquires meaning.--But this understanding, the knowledge of the language, isn't a conscious state that accompanies the sentences of the language. Not even if one of its consequences is such a state. It's much more like the understanding or mastery of a calculus, something like the *ability* to multiply.

Page 50

12 Suppose it were asked: "When do you know how to play chess? All the time? Or just while you say that you can? Or just during a move in the game?"--How queer that knowing how to play chess should take such a short time, and a game of chess so much longer!

Page 50

(Augustine: "*When* do I measure a period of time?")

Page 50

It can seem as if the rules of grammar are in a certain sense an unpacking of something we experience all at once when we use a word.

Page 50

In order to get clearer about the grammar of the word "understand", let's ask: *when* do we understand a sentence?--When we've uttered the whole of it? Or while uttering it?--Is understanding, like the uttering of a sentence, an articulated process and does its articulation correspond exactly to that of the sentence? Or is it non-articulate, something accompanying the sentence in the way a pedal note accompanies a melody?

Page 50

How long does it take to understand a sentence?

Page 50

And if we understand a sentence for a whole hour, are we always starting afresh?

Page 50

13 Chess is characterized by its rules (by the list of rules). If I define the game (distinguish it from draughts) by its rules, then

Page Break 51

these rules belong to the grammar of the word "chess". Does that mean that if someone uses the word "chess" intelligently he must have a definition of the word in mind? Certainly not.--He will only give one if he's asked what he means by "chess".

Page 51

Suppose I now ask: "When you uttered the word, what did you mean by it?"--If he answered "I meant the game we've played so often, etc. etc." I would know that this explanation hadn't been in his mind at all when he used the word, and that he wasn't giving an answer to my question in the sense of telling me what "went on inside him" while he was uttering the word.

Page 51

When someone interprets, or understands, a sign in one sense or another, what he is doing is taking a step in a calculus (like a calculation). What he does is roughly what he does if he gives expression to his interpretation.

Page 51

"Thought" sometimes means a particular mental process which may accompany the utterance of a sentence and sometimes the sentence itself in the system of language.

Page 51

"He said those words, but he didn't think any thoughts with them."--"Yes, I did think a thought while I said them". "*What* thought?" "Just what I said."

Page 51

On hearing the assertion "This sentence makes sense" you cannot really ask "what sense?" Just as on hearing the assertion "this combination of words is a sentence" you cannot ask "what sentence?"

Page Break 52

II

Page 52

14 Can what the rules of grammar say about a word be described in another way by describing the process which

takes place when understanding occurs?

Page 52

Suppose the grammar is the geometry of negation for example, can I replace it by the description of what "lies behind" the word "not" when it is applied?

Page 52

We say: "Anyone who understands negation knows that two negations yield an affirmation."

Page 52

That sounds like "Carbon and oxygen yield carbonic acid". But in reality a doubled negation does not *yield* anything, it *is* something.

Page 52

Something here gives us the illusion of a fact of physics. As if we saw the result of a logical process. Whereas the only result is the result of the physical process.

Page 52

We would like to say: "Negation has the property that when it is doubled it yields an affirmation," But the rule doesn't give a further description of negation, it constitutes negation.

Page 52

Negation has the property that it denies truly such and such a sentence.

Page 52

Similarly, a circle--say one painted on a flat surface--has the property of being in such and such a position, of having the colour it has, of being bisected by a certain line (a boundary between two colours) and so on; but it doesn't have the properties that geometry seems to ascribe to it (i.e. the *ability* to have the other properties).

Page 52

Likewise one doesn't have the property that when it's added to itself it makes two.

Page 52

15 Geometry no more speaks about cubes than logic does about negation.

Page 52

Geometry defines the form of a cube but does not describe it. If the description of a cube says that it is red and hard, then 'a

Page Break 53

description of the form of a cube' is a sentence like "This box has the form of a cube".

Page 53

But if I describe how to make a cubical box, doesn't this contain a description of the form of a cube? A description only insofar as this thing is said to be cubical, and for the rest an analysis of the concept of cube.

Page 53

"This paper is *not* black, and two such negations yield an affirmation".

Page 53

The second clause is reminiscent of "and two such horses can pull the cart". But it contains no assertion about negation; it is a rule for the replacement of one sign by another.

Page 53

"That two negations yield an affirmation must already be contained in the negation that I am using now." Here I am on the verge of inventing a mythology of symbolism.

Page 53

It looks as if one could *infer* from the meaning of negation that " $\sim\sim p$ " means p . As if the rules for the negation sign *follow from* the nature of negation. So that in a certain sense there is first of all negation, and then the rules of grammar.

Page 53

It also looks as if the essence of negation had a double expression in language: the one whose meaning I grasp when I understand the expression of negation in a sentence, and the consequences of this meaning in the grammar.

Page 53

16 What does it mean to say that the "is" in "The rose is red" has a different meaning from the "is" in "Twice two is four"? If it is answered that it means that different rules are valid for these two words, we can say that we have only *one* word here.--And if all I am attending to is grammatical rules, these do allow the use of the word "is" in both connections.--But the rule which shews that the word "is" has different meanings in the two sentences is the one

Page Break 54

allowing us to replace the word "is" in the second sentence by "equals" and forbidding this substitution in the first sentence.

Page 54

"Is this rule then only the consequence of the *first* rule, that the word 'is' has different meanings in the two sentences? Or is it rather that this very rule is the expression of the word's having a different meaning in the two contexts?"

Page 54

It looks as if a sentence with e.g. the word "ball" in it already contained the shadow of other uses of this word. That is to say, the *possibility* of forming those other sentences. To whom does it look like that? And under what circumstances?

Page 54

The comparison suggests itself that the word "is" in different cases has different *meaning-bodies* behind it; that it is perhaps each time a square surface, but in one case it is the end surface of a prism and in the other the end surface of a pyramid.

Page 54

Imagine the following case. Suppose we have some completely transparent glass cubes which have one face painted red. If we arrange these cubes together in space, only certain arrangements of red squares will be permitted by the shape of the glass bodies. I might then express the rule for the possible arrangements of the red squares without mentioning the cubes; but the rule would none the less contain the essence of the form of cube--Not, of course, the fact that there are glass cubes behind the red squares, but the geometry of the cube.

Page 54

But suppose we *see* such a cube: are we immediately presented with the rules for the possible combinations, i.e. the geometry of the cube? Can I read off the geometry of the cube from a cube?

Page 54

Thus the cube is a notation for the rule. And if we had discovered such a rule, we really wouldn't be able to find anything better than the drawing of a cube to use as a notation for it. (And it is significant that here a drawing of a cube will do instead of a cube.)

Page Break 55

Page 55

But how can the cube (or the drawing) serve as a notation for a geometrical rule? Only if it belongs, as a proposition or part of a proposition, to a system of propositions.

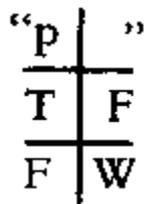

Page 55

17 "Of course the grammatical possibilities of the negation sign reveal themselves bit by bit in the use of the signs, but I *think* negation all at once. The sign 'not' is only a pointer to the thought 'not'; it is only a stimulus to produce the right thought, only a signal."

Page 55

(If I were asked what I mean by the word "and" in the sentence "pass me the bread and butter" I would answer by a gesture of gathering together; and that gesture would illustrate what I mean, in the same way as a green pattern illustrates the meaning of "green" and the T-F notation illustrates the meaning of "not", "and" etc.)

Page 55

For instance, this sign for negation: is worth no more and no less than any other negation sign; it is a complex of lines just like the expression "not-p" and it is only made into a sign for negation by the way it *works*--I mean, the way it is used in the game.

Page 55

(The same goes for the T-F schemata for tautology and contradiction.)

Page 55

What I want to say is that to be a sign a thing must be dynamic, not static.

Page 55

18 Here it can easily seem as if the sign contained the whole of the grammar; as if the grammar were contained in the sign like a string of pearls in a box and he had only to pull it out. (But this kind of picture is just what is misleading us). As if understanding were an instantaneous grasping of something from which later we only draw consequences which already exist in an ideal sense before they are drawn. As if the cube already contained the geometry of the

cube, and I had only to unpack it. But which cube? Or is there

Page Break 56

an ideal geometrical cube?--Often we have in mind the process of deriving geometrical propositions from a drawing, a representation (or a model). But what is the role of the model in such a case? It has the role of a sign, a sign employed in a particular game.--And it is an interesting and remarkable thing how this sign is employed, how we perhaps use the drawing of a cube again and again in different contexts.--And it is this sign, (*which has the identity proper to a sign*) that we take to be the cube in which the geometrical laws are already laid up. (They are no more laid up there than the disposition to be used in a certain way is laid up in the chessman which is the king).

Page 56

In philosophy one is constantly tempted to invent a mythology of symbolism or of psychology, instead of simply saying what we know.

Page 56

19 The concept of meaning I adopted in my philosophical discussions originates in a primitive philosophy of language.

Page 56

The German word for "meaning" is derived from the German word for "pointing".

Page 56

When Augustine talks about the learning of language he talks about how we attach names to things, or understand the names of things. *Naming* here appears as the foundation, the be all and end all of language.

Page 56

Augustine does not speak of there being any difference between parts of speech and means by "names" apparently words like "tree", "table", "bread" and of course, the proper names of people; also no doubt "eat", "go", "here", "there"--all words, in fact. Certainly he's thinking first and foremost of *nouns*, and of the remaining words as something that will take care of itself. (Plato too says that a sentence consists of nouns and verbs.)†1

Page Break 57

Page 57

They describe the game as simpler than it is.

Page 57

But the game Augustine describes is certainly a part of language. Imagine I want to put up a building using building stones someone else is to pass me; we might first make a convention by my pointing to a building stone and saying "that is a pillar", and to another and saying "that is called 'a block' ", "that is called 'a slab'" and so on. And then I call out the words "pillar", "slab", etc. in the order in which I need the stones.

Page 57

Augustine does describe a calculus of our language, only not everything that we call language is this calculus. (And one has to say this in many cases where we are faced with the question "Is this an appropriate description or not?" The answer is: "Yes, it is appropriate, but only *here*, and not for the whole region that you were claiming to describe.") So it could be said that Augustine represents the matter too simply; but also that he represents something simpler.

Page 57

It is as if someone were to say "a game consists in moving objects about on a surface according to certain rules..." and we replied: You must be thinking of board games, and your description is indeed applicable to them. But they are not the only games. So you can make your definitions correct by expressly restricting it to those games.

Page 57

20 The way Augustine describes the learning of language can show us the way of looking at language from which the concept of the meaning of words derives.

Page 57

The case of our language could be compared with a script in which the letters were used to stand for sounds, and also as signs of emphasis and perhaps as marks of punctuation. If one conceives this script as a language for describing sound-patterns, one can imagine someone misinterpreting the script as if there were simply a correspondence of letters to sounds and as if the letters had not also completely different functions.

Page Break 58

Page 58

Just as the handles in the cabin of a locomotive have different kinds of job, so do the words of language,

which in one way are like handles. One is the handle of a crank, it can be moved continuously since it operates a valve; another works a switch, which has two positions; a third is the handle of a pump and only works when it is being moved up and down etc. But they all look alike, since they are all worked by hand.

Page 58

A connected point: it is possible to speak perfectly intelligibly of *combinations of colours and shapes* (e.g. of the colours red and blue and the shapes square and circle) just as we speak of combinations of different shapes or spatial objects. And this is the origin of the bad expression: a fact is a complex of objects. Here the fact that a man is sick is compared with a combination of two things, one of them the man and the other the sickness.

Page 58

21 A man who reads a sentence in a familiar language experiences the different parts of speech in quite different ways. (Think of the comparison with meaning-bodies.) We quite forget that the written and spoken words "not", "table" and "green" are similar to each other. It is only in a foreign language that we see clearly the uniformity of words. (Compare William James on the feelings that correspond to words like "not", "but" and so on.)

Page 58

("Not" makes a gesture of rejection.

Page 58

No, it *is* a gesture of rejection. To grasp negation is to understand a gesture of rejection.)

Page 58

Compare the different parts of speech in a sentence with lines on a map with different functions (frontiers, roads, meridians, contours.) An uninstructed person sees a mass of lines and does not know the variety of their meanings.

Page Break 59

Page 59

Think of a line on a map crossing a sign out to show that it is void

Page 59

The difference between parts of speech is comparable to the differences between chessmen, but also to the even greater difference between a chessman and the chess board.

Page 59

22 We say: the essential thing in a word is its *meaning*. We can replace the word by another with the same meaning. That fixes a place for the word, and we can substitute one word for another provided we put it in the same place.

Page 59

If I decide to say a new word instead of "red" (perhaps only in thought), how would it come out that it took the place of the word "red"?

Page 59

Suppose it was agreed to say "non" in English instead of "not", and "not" instead of "red". In that case the word "not" would remain in the language, and one could say that "non" was now used in the way in which "not" used to be, and that "not" now had a *different* use.

Page 59

Would it not be similar if I decided to alter the shape of the chess pieces, or to use a knight-shaped piece as the king? How would it be clear that the knight is the king? In this case can't I very well talk about a change of meaning?

Page 59

23 I want to say the place of a word in grammar is its meaning.

Page 59

But I might also say: the meaning of a word is what the explanation of its meaning explains.

Page 59

"What 1 c.c. of water weighs is called '1 gram'--Well, what *does* it weigh?"

Page 59

The explanation of the meaning explains the use of the word.

Page Break 60

Page 60

The use of a word in the language is its meaning.

Page 60

Grammar describes the use of words in the language.

Page 60

So it has somewhat the same relation to the language as the description of a game, the rules of a game, have to the game.

Page 60

Meaning, in our sense, is embodied in the explanation of meaning. If, on the other hand, by the word "meaning" we mean a characteristic sensation connected with the use of a word, then the relation between the explanation of a word and its meaning is rather that of cause to effect.

Page 60

24 An explanation of meaning can remove every *disagreement* with regard to a meaning. It can clear up misunderstandings.

Page 60

The understanding here spoken of is a correlate of explanation.

Page 60

By "explanation of the meaning of a sign" we mean rules for use but above all *definitions*. The distinction between verbal definitions and ostensive definitions gives a rough division of these types of explanation.

Page 60

In order to understand the role of a definition in the calculus we must investigate the particular case.

Page 60

It may seem to us as if the other grammatical rules for a word had to follow from its ostensive definition; since after all an ostensive definition, e.g. "that is called 'red'" determines the meaning of the word "red".

Page 60

But this definition is only those words plus pointing to a red object, e.g. a red piece of paper. And is this definition really unambiguous? Couldn't I have used the very same one to give the word "red" the meaning of the word "paper", or "square", or "shiny", or "light", or "thin" etc. etc.?

Page 60

However, suppose that instead of saying "that is called 'red'"

Page 60

Page Break 61

I had phrased my definition "that colour is called 'red'". That certainly is unambiguous, but only because the expression "colour" settles the grammar of the word "red" up to this last point. (But here questions could arise like "do you call just *this* shade of colour red, or also other similar shades?"). Definitions might be given like this: the colour of this patch is called "red", its shape "ellipse".

Page 61

I might say: one must already understand a great deal of a language in order to understand that definition. Someone who understands that definition must already know where the words ("red", "ellipse") are being put, where they belong in language.

Page 61

25 The words "shape" and "colour" in the definitions determine the *kind of use* of the word, and therefore what one may call the *part of speech*. And in ordinary grammar one might well distinguish "shape words", "colour words", "sound words", "substance words" and so on as different parts of speech. (There wouldn't be the same reason for distinguishing "metal words", "poison words", "predator words". It makes sense to say "iron is a metal", "phosphorus is a poison", etc. but not "red is a colour", "a circle is a shape" and so on.)

Page 61

I can ostensively define a word for a colour or a shape or a number, etc. etc. (children are given ostensive explanations of numerals and they do perfectly well); negation, too, disjunction and so on. The *same* ostension might define a numeral, or the name of a shape or the name of a colour. But in the grammar of each different part of speech the ostensive definition has a different role; and in each case it is only *one* rule.

Page 61

(Consider also the grammar of definitions like: "today is called Monday", "I will call this day of the year 'the day of atonement'").

Page 61

26 But when we learn the meaning of a word, we are very often given *only* the single rule, the ostensive definition. So how does it

Page Break 62

come about that on the strength of this definition we understand the word? Do we guess the rest of the rules?

Page 62

Think also of teaching a child to understand words by showing it objects and uttering words. The child is

given ostensive definitions and then it understands the words.--But what is the criterion of understanding here? Surely, that the child applies the words correctly. Does it guess rules?--Indeed we must ask ourselves whether we are to call these signs and utterances of words "definitions" at all. The language game is still very simple and the ostensive definition has not the same role in this language-game as in more developed ones. (For instance, the child cannot yet ask "What is that called?") But there is no sharp boundary between primitive forms and more complicated ones. I wouldn't know what I can and what I can't still call "definition". I can only describe language games or calculi; whether we still want to call them calculi or not doesn't matter as long as we don't let the use of the general term divert us from examining each particular case we wish to decide.

Page 62

I might also say of a little child "he can use the word, he knows how it is applied." But I only see what that means if I ask "what is the criterion for this knowledge?" In this case it isn't the ability to state rules.

Page 62

What's the sign of someone's understanding a game? Must he be able to recite the rules? Isn't it also a criterion that he can play the game, i.e. that he does in fact play it, even if he's baffled when asked for the rules? Is it only by being told the rules that the game is learnt and not also simply by watching it being played? Of course a man will often say to himself while watching "oh, so that's the rule"; and he might perhaps write down the rules as he observes them; but there's certainly such a thing as learning the game without explicit rules.

Page 62

The grammar of a language isn't recorded and doesn't come into existence until the language has already been spoken by human

Page Break 63

beings for a *long* time. Similarly, primitive games are played without their rules being codified, and even without a single rule being formulated.

Page 63

But we look at games and language under the guise of a game played according to rules. That is, we are always *comparing* language with a procedure of that kind.

Page 63

27 The names I give to bodies, shapes, colours, lengths have different grammars in each case. ("A" in "A is yellow" has one grammar if A is a body and another if A is the surface of a body; for instance it makes sense to say that the body is yellow all through, but not to say that the surface is.) And one points in different sense to a body, and to its length or its colour; for example, a possible definition would be: "to point to a colour" means, to point to the body which has the colour. Just as a man who marries money doesn't marry it in the same sense as he marries the woman who owns the money.

Page 63

Money, and what one buys with it. Sometimes a material object, sometimes the right to a seat in the theatre, or a title, or fast travel, or life, etc.

Page 63

A name has meaning, a proposition has sense in the calculus to which it belongs. The calculus is as it were autonomous.--Language must speak for itself.

Page 63

I might say: the only thing that is of interest to me is the *content* of a proposition and the content of a proposition is something internal to it. A proposition has its content as part of a calculus.

Page 63

The meaning is the role of the word in the calculus.

Page 63

The meaning of a name is not the thing we point to when we give an ostensive definition of the name; that is, it is not the bearer of

Page Break 64

the name.--The expression "the bearer of the name 'N'" is synonymous with the name "N". The expression can be used in place of the name. "The bearer of the name 'N' is sick" means "N is sick". We don't say: The meaning of "N" is sick.

Page 64

The name doesn't lose its meaning if its bearer ceases to exist (if he dies, say).

Page 64

But doesn't "Two names have a single bearer" mean the same as "two names have the same meaning?"

Certainly, instead of "A = B" one can write "the bearer of the name 'A' = the bearer of the name 'B'".

Page 64

28 What does "to understand a word" mean?

Page 64

We say to a child "No, no more sugar" and take it away from him. Thus he learns the meaning of the word "no". If, while saying the same words, we had given him a piece of sugar he would have learnt to understand the word differently. (In this way he has learnt to use the word, but also to associate a particular feeling with it, to experience it in a particular way.)

Page 64

What constitutes the meaning of a word like "perhaps"? How does a child learn the use of the word "perhaps"? It may repeat a sentence it has heard from an adult like "*perhaps* she will come"; it may do so in the same tone of voice as the adult. (That is a kind of a game). In such a case the question is sometimes asked: Does it already understand the word "perhaps" or is it only repeating it?--What shows that it really understands the word?--Well, that it uses it in particular circumstances in a particular manner--in certain contexts and with a particular intonation.

Page 64

What does it mean "to understand the word 'perhaps'"?--Do *I* understand the word "perhaps"?--And how do I judge whether I do? Well, something like this: I know how it's used, I can explain its use to somebody, say by describing it in made-up cases. I can describe the occasions of its use, its position in sentences, the intonation it has in speech.--Of course this only means that "I

Page Break 65

understand the word 'perhaps'" comes to the same as: "I know how it is used etc."; not that I try to call to mind its entire application in order to answer the question whether I understand the word. More likely I would react to this question immediately with the answer "yes", perhaps after having said the word to myself once again, and as it were convinced myself that it's familiar, or else I might think of a single application and pronounce the word with the correct intonation and a gesture of uncertainty. And so on.

Page 65

This is like the case in which someone is explaining to me a calculation "that I don't quite understand", and when he has reached a particular point of his explanation, I say: "ah, now I understand; now I know how to go on". How do I know that I know how to go on? Have I run through the rest of the calculation at that moment? Of course not. Perhaps a bit of it flashed before my mind; perhaps a particular application or a diagram. If I were asked: how do you know that you can use the word "perhaps" I would perhaps simply answer "I have used it a hundred times".

Page 65

29 But it might be asked: Do I *understand* the word just by describing its application? Do I understand its point? Haven't I deluded myself about something important?

Page 65

At present, say, I know only how men use this word. But it might be a game, or a form of etiquette. I do not know why they behave in this way, how *language* meshes with their life.

Page 65

Is meaning then really only the use of a word? Isn't it the way this use meshes with our life?

Page 65

But isn't its use a part of our life?

Page 65

Do I understand the word "fine" when I know how and on what occasions people use it? Is that enough to enable me to use it myself? I mean, so to say, use it with conviction.

Page 65

Wouldn't it be possible for me to know the use of the word and yet follow it without understanding? (As, in a sense, we follow the

Page Break 66

singing of birds). So isn't it something else that constitutes understanding--the feeling "in one's own breast", the living experience of the expressions?--They must mesh with *my own* life.

Page 66

Well, language does connect up with my own life. And what is called "language" is something made up of heterogeneous elements and the way it meshes with life is infinitely various.

Page 66

30 We may say that the words "fine", "oh", and also "perhaps" are *expressions* of sensation, of feeling. But I don't call the feeling the meaning of the word. We are not interested in the relation of the words to the sensation [[sic]], whatever it may be, whether they are evoked by it, or are regularly accompanied by it, or give it an outlet. We are not interested in any empirical facts about language, considered as empirical facts. We are only concerned with the description of what happens and it is not the truth but the form of the description that interests us. What happens considered as a game.

Page 66

I am only *describing* language, not *explaining* anything.

Page 66

For my purposes I could replace the sensation the word is said to express by the intonation and gestures with which the word is used.

Page 66

I might say: in many cases understanding a word involves being able to use it on certain occasions in a special tone of voice.

Page 66

You might say that certain words are only pegs to hang intonations on.

Page 66

But instead of the intonation and the accompanying gestures, I might for my own purposes treat the word itself as a gesture. (Can't I say that the sound "ha ha" is a laugh and the sound "oh!" is a sigh?)

Page Break 67

Page 67

31 I could imagine a language that was spoken in a uniform metre, with quasi-words intercalated between the words of the sentences to maintain the metre. Suppose we talked about the meaning of these quasi-words. (The smith putting in extra taps between the real strokes in order to maintain a rhythm in striking).

Page 67

Language is like a collection of very various tools. In the tool box there is a hammer, a saw, a rule, a lead, a glue pot and glue. Many of the tools are akin to each other in form and use, and the tools can be roughly divided into groups according to their relationships; but the boundaries between these groups will often be more or less arbitrary and there are various types of relationship that cut across one another.

Page 67

I said that the meaning of a word is its role in the calculus of language. (I compared it to a piece in chess). Now let us think how we calculate with a word, for instance with the word "red". We are told where the colour is situated; we are told the shape and size of the coloured patch or the coloured object; we are told whether the colour is pure or mixed, light or dark, whether it remains constant or changes, etc. etc. Conclusions are drawn from the propositions, they are translated into diagrams and into behaviour, there is drawing, measurement and calculation. But think of the meaning of the word "oh!" If we were asked about it, we would say "'oh!' is a sigh; we say, for instance, things like 'Oh, it is raining again already'". And that would describe the use of the word. But what corresponds now to the calculus, the complicated game that we play with other words? In the use of the words "oh!", or "hurrah", or "hm", there is nothing comparable.

Page 67

Moreover, we mustn't confuse signs with symptoms here. The sound "hm" may be called an expression of dubiousness and also, for other people, a *symptom* of dubiousness, in the way that

Page Break 68

clouds are a symptom of rain. But "hm" is not the *name* of dubiousness.

Page 68

32 Suppose we want to describe *ball-games*. There are some games like football, cricket and tennis, which have a well-developed and complicated system of rules; there is a game consisting simply of everyone's throwing a ball as high as he can; and there is the game little children play of throwing a ball in any direction and then retrieving it. Or again someone throws a ball high into the air for the fun of it and catches it again without any element of competition. Perhaps one will be unwilling to call some of these ball games at all; but is it clear where the boundary is to be drawn here?

Page 68

We are interested in language as a procedure according to explicit rules, because philosophical problems are misunderstandings which must be removed by clarification of the rules according to which we are inclined to use words.

We consider language from one point of view only.

We said that when we understood the use we didn't yet understand the *purpose* of the word "perhaps". And by "purpose" in this case we meant the role in human life. (This role can be called the "meaning" of the word in the sense in which one speaks of the 'meaning of an event for our life'.)

But we said that by "meaning" we meant what an explanation of meaning explains. And an explanation of meaning is not an empirical proposition and not a causal explanation, but a rule, a convention.

It might be said that the purpose of the word "hey!" in our language is to alarm the person spoken to. But what does its having this purpose amount to? What is the criterion for it? The word "purpose" like all the words of our language is used in various more or less related ways. I will mention two characteristic games. We might say that the purpose of doing something is what the person doing it would say if asked what its purpose was. On the

other hand if we say that the hen clucks in order to call her chicks together we infer this purpose from the *effect* of the clucking. We wouldn't call the gathering of the chicks the purpose of the clucking if the clucking didn't have this result always, or at least commonly or in specifiable circumstances.--One may now say that the purpose, the effect of the word "hey" is the important thing about the word; but explaining the purpose or the effect is not what we call explaining the meaning.

It may be that if it is to achieve its effect a particular word cannot be replaced by any other; just as it may be that a gesture cannot be replaced by any other. (The word has a *soul* and not just a meaning.) No one would believe that a poem remained *essentially unaltered* if its words were replaced by others in accordance with an appropriate convention.

Our proposition "meaning is what an explanation of meaning explains" could also be interpreted in the following way: let's only bother about what's called the explanation of meaning, and let's not bother about meaning in any other sense.

33 But one might say something like this. The sentences that we utter have a particular purpose, they are to produce certain effects. They are parts of a mechanism, perhaps a psychological mechanism, and the words of the sentences are also parts of the mechanism (levers, cogwheels and so on). The example that seems to illustrate what we're thinking of here is an automatic music player, a pianola. It contains a roll, rollers, etc., on which the piece of music is written in some kind of notation (the position of holes, pegs and so on). It's as if these written signs gave orders which are carried out by the keys and hammers. And so shouldn't we say that the sense of the sign is its effect?--But suppose the pianola is in bad condition and the signs on the roll produce hisses and bangs instead of the notes.--Perhaps you will say that the sense of the signs is their effect on a mechanism in good condition, and correspondingly

that the sense of an order is its effect on an obedient man. But what is regarded as a criterion of obedience here?

You might then say that the sense of the signs is not their effect, but their purpose. But consider too, that we're tempted to think that this purpose is only a part of the larger purpose served by the pianola.--This purpose, say, is to entertain people. But it's clear that when we spoke of "the sense of the signs" we didn't mean any part of *that* purpose. We were thinking rather of the purpose of the signs *within* the mechanism of the pianola.--And so you can say that the purpose of an order is its sense, only so far as the purpose can be expressed by a rule of language. "I am saying 'go away' because I want you to leave me alone", "I am saying 'perhaps' because I am not quite sure."

An explanation of the operation of language as a psychophysical mechanism is of no interest to us. Such an explanation itself uses language to describe phenomena (association, memory etc); it is itself a linguistic act and stands outside the calculus; but we need an explanation which is *part of the calculus*.

"How is he to know what colour he is to pick out when he hears the word 'red'?--Very simple: he is to take

the colour whose image occurs to him when he hears the word"--But how will he know what that means, and which colour it is "which occurs to him when he hears the word"?

Page 70

Certainly there is such a procedure as choosing the colour which occurs to you when you hear that word. And the sentence "red is the colour that occurs to you when you hear the word 'red'" is a definition.

Page 70

If I say, "a symbol is something which produces this effect" the question remains: how can I speak of "this effect"? And if it occurs, how do I know that it's *the one I meant*?" "Very simple", we may say "we compare it with our memory image." But this explanation does not get to the root of our dissatisfaction. For

Page Break 71

how are we given the method we're to use in making the comparison--i.e. how do we know what we're to do when we're told to compare?

Page 71

In our language one of the functions of the word "red" is to call that particular colour to mind; and indeed it might be discovered that this word did so better than others, even that it alone served that purpose. But instead of the mechanism of association we might also have used a colour chart or some such apparatus; and then our calculus would have to get along with the associated, or visible, colour sample. The psychological effectiveness of a sign does not concern us. I wouldn't even scruple to invent that kind of mechanism.

Page 71

Investigating whether the meaning of a word is its effect or its purpose, etc. is a grammatical investigation.

Page 71

34 Why can one understand a word and not a penholder? Is it the difference between their shapes? But you will say that we could understand a penholder too, if we had given it a meaning. But then how is giving it a meaning done?--How was meaning given to the word "red"? Well, you point at something, and you say "I call that 'red'". Is that a kind of consecration of mystical formula? How does this pointing and uttering words work? It works only as part of a system containing other bits of linguistic behaviour. And so now one can understand a penholder too; but does this understanding contain the whole system of its application? Impossible. We say that we understand its meaning when we know its use, but we've also said that the word "know" doesn't denote a state of consciousness. That is: the grammar of the word "know" isn't the grammar of a "state of consciousness", but something different. And there is only one way to learn it: to watch how the word is used in practice.

Page 71

A truthful answer to the question "Did you understand the

Page Break 72

sentence (that you have just read)" is sometimes "yes" and sometimes "no". "So something different must take place when I understand it and when I don't understand it."

Page 72

Right. So when I understand a sentence something happens like being able to follow a melody as a melody, unlike the case when it's so long or so developed that I have to say "I can't follow this bit". And the same thing might happen with a picture, and here I mean an ornament. First of all I see only a maze of lines; then they group themselves for me into well-known and accustomed forms and I see a plan, a familiar system. If the ornamentation contains representations of well-known objects the recognition of these will indicate a further stage of understanding. (Think in this connection of the solution of a puzzle picture.) I then say "Yes, now I see the picture rightly".

Page 72

Asked "what happened when you read that sentence with understanding" I would have to say "I read it as a group of English words linked in a familiar way". I might also say that a picture came into my mind when I heard it. But then I am asked: "Is that all? After all, the understanding couldn't consist in that and nothing else!" Well, that or something like it is all that happened while I read the sentence and immediately afterwards; but what we call "understanding" is related to countless things that happen before and after the reading of *this* sentence.

Page 72

What of when I don't understand a sentence? Well, it might be a sentence in a foreign language and all I see is a row of unknown words. Or what I read seemed to be an English sentence, but it contained an unfamiliar phrase and when I tried to grasp it (and that again can mean various things) I didn't succeed. (Think of what goes on when we try to understand the sense of a poem in our native language which makes use of constructions we don't yet understand.)

But I can say that I understand a sentence in a foreign language

say a Latin one that I can only decipher by a painful effort to construe--even if I have only turned it into English bit by bit and have never succeeded in grasping the overall phrasing of the sentence.

But all the same, in order to understand a sentence I have to understand the words in it! And when I read, I understand some words and not others.

I hear a word and someone asks me "did you understand it?" and I reply truly "yes". What happened when I understood? How was the understanding different from what happens when I don't understand a word?--Suppose the word was "tree". If I am to say truly that I understood it, must the image of a tree have come before my mind? No; nor must any other image. All I can say is that when I was asked "do you understand the word tree?" I'd have answered "yes" unthinkingly and without lying.--If the other person had asked me further "and what is a tree?" I would have described one for him, or shown him one, or drawn one; or perhaps I would have answered "I know, but I don't want to explain." And it may be that when I gave my reply the image of a tree came before my mind, or perhaps I looked for something which had some similarity with a tree, or perhaps other words came into my head, etc. etc.

Let's just look how we actually use the word "understand".

The word might also have been one of which I would say "I used to know what it meant, and it will come back to me", and then later on say "now it's come back to me". What happened then?--Perhaps there came into my mind the situation in which the word was first explained to me: I saw myself in a room with others, etc. etc. (But if now I read and understand the word in a sentence that picture wouldn't have to come before my mind; perhaps no picture at all comes to mind.)

Or it was a word in a foreign language; and I had already often heard it, but never understood it. Perhaps I said to myself "what can it mean?" and tried to give it a meaning which fitted the context

(again various possibilities). Perhaps now this situation comes to mind and I say "I don't understand the word". But I might also react immediately to the foreign word with the answer "I don't understand it", just as I reacted to the word "tree" with the opposite answer.

Suppose it is the word "red" and I say automatically that I understood it; then he asks again "do you really understand it?" Then I summon up a red image in my mind as a kind of check. But how do I know that it's the right colour that appears to me? And yet I say now with full conviction that I understand it.--But I might also look at a colour chart with the word "red" written beneath the colour.--I could carry on for ever describing such processes.

35 The problem that concerns us could be summed up roughly thus: "Must one see an image of the colour blue in one's mind whenever one reads the word 'blue' with understanding?" People have often asked this question and have commonly answered no; they have concluded from this answer that the characteristic process of understanding is just a different process which we've not yet grasped.--Suppose then by "understanding" we mean what makes the difference between reading with understanding and reading without understanding; what *does* happen when we understand? Well, "Understanding" is not the name of a single process accompanying reading or hearing, but of more or less interrelated processes against a background, or in a context, of facts of a particular kind, viz. the actual use of a learnt language or languages.--We say that understanding is a "psychological process", and this label is misleading, in this as in countless other cases. It compares understanding to a particular *process* like translation from one language into another, and it suggests the same conception of thinking, knowing, wishing, intending, etc. That is to say, in all these cases we see that what we would perhaps naively suggest as the hallmark of such a process is not present in

every case or even in the majority of cases. And our next step is to conclude that the essence of the process is something difficult to grasp that still awaits discovery. For we say: since I use the word "understand" in all these

cases, there must be some one thing which happens in every case and which is the essence of understanding (expecting, wishing etc.). Otherwise, why should I call them by all the same name?

Page 75

This argument is based on the notion that what is needed to justify characterizing a number of processes or objects by a general concept-word is something common to them all.

Page 75

This notion is, in a way, *too primitive*. What a concept-word indicates is certainly a kinship between objects, but this kinship need not be the sharing of a common property or a constituent. It may connect the objects like the links of a chain, so that one is linked to another *by intermediary links*. Two neighbouring members may have common features and be *similar* to each other, while distant ones belong to the same family without any longer having anything in common. Indeed even if a feature is common to all members of the family it need not be that feature that defines the concept.

Page 75

The relationship between the members of a concept may be set up by the sharing of features which show up in the family of the concept, crossing and overlapping in very complicated ways.

Page 75

Thus there is probably no single characteristic which is common to all the things we call games. But it can't be said either that "game" just has several independent meanings (rather like the word "bank"). What we call "games" are procedures interrelated in various ways with many different transitions between one and another.

Page 75

It might be said that the use of the concept-word or common noun is justified in this case because there are transitional steps

Page Break 76

between the members.--Then it might be objected that a transition can be made from anything to anything, and so the concept isn't bounded. To this I have to say that for the most part it isn't in fact bounded and the way to specify it is perhaps: "by 'knowledge' we mean these processes, and these, *and similar ones*". And instead of "and similar ones" I might have said "and others akin to these in many ways".

Page 76

But if we wish to draw boundaries in the use of a word, in order to clear up philosophical paradoxes, then alongside the actual picture of the use (in which as it were the different colours flow into one another without sharp boundaries) we may put another picture which is in certain ways like the first but is built up of colours with clear boundaries between them.

Page Break 77

III

Page 77

36 If we look at the actual use of a word, what we see is something constantly fluctuating.

Page 77

In our investigations we set over against this fluctuation something more fixed, just as one paints a stationary picture of the constantly altering face of the landscape.

Page 77

When we study language we *envisage* it as a game with fixed rules. We compare it with, and measure it against, a game of that kind.

Page 77

If for our purposes we wish to regulate the use of a word by definite rules, then alongside its fluctuating use we set up a different use by codifying one of its characteristic aspects.

Page 77

Thus it could be said that the use of the word "good" (in an ethical sense) is a combination of a very large number of interrelated games, each of them as it were a facet of the use. What makes a single concept here is precisely the connection, the relationship, between these facets.

Page 77

But this isn't like the way physics gives a simplified description of a natural phenomenon, abstracting from secondary factors. It can't be said that logic depicts an idealised reality, or that it holds strictly only for an ideal language and so on. For where do we get the concept of this ideal? The most that could be said is that we are *constructing* an ideal language which contrasts with ordinary language; but it can't be said that we are *saying* something that would hold only of an ideal language.

37 There is something else I would like to say about the understanding of a picture. Take a genre-picture: we say we understand

it if we recognise what is happening in it, what the people in it are doing. Here the criterion for this recognition is perhaps that if asked what they are doing we explain it in words or represent it in mime etc. It's possible that this recognition doesn't come easily, perhaps because we don't immediately see the figures in the picture as figures (as in puzzle pictures), perhaps because we can't make out what they are doing together, etc. In these cases there may be a period of doubt followed by a familiar process of recognition. On the other hand, it may be the kind of picture we'd say we took in at first glance, and in that case we find it difficult to say what the understanding really consists of. In the first place what happened was not that we took the painted objects for real ones. And again "I understand it" in this case doesn't mean that finally, after an effort, I understand that it is *this* picture. And nothing takes place like recognizing an old acquaintance in the street, no saying "oh, there's... ". If you insist on saying there is a recognition, what does this recognition consist of? Perhaps I recognize a certain part of the picture as a human face. Do I have to look at a real face, or call before my mind's eye the memory of a face I've seen before? Is what happens that I rummage in the cupboard of my memory until I find something which resembles the picture? Is the recognition just this finding? In our case there is no one thing that happens that could be called recognition, and yet if the person who sees the picture is asked "do you recognize what it is?" he may truly answer "yes", or perhaps reply "it is a face". It can indeed be said that when he sees the complex of signs as a face he sees something different from when he doesn't do so. In that case I'd like to say that I see something *familiar*†1 in front of me. But what constitutes the familiarity is not the historical fact that I've often seen objects like that etc; because the history behind the experience is certainly not present in the experience itself. Rather, the familiarity

lies in the fact that I immediately grasp a particular rhythm of the picture and stay with it, feel at home with it, so to speak. For the rest it is a different experience that constitutes the familiarity in each particular case; a picture of a table carries one experience with it and a picture of a bed another.

If I say: "I understand this picture" the question arises: do I mean "I understand it *like that*"? With the "*like that*" standing for a translation of what I understand into a different expression? Or is it a sort of intransitive understanding? When I'm understanding one thing do I as it were think of another thing? Does understanding, that is, consist of thinking of something else? And if that isn't what I mean, then what's understood is as it were autonomous, and the understanding of it is comparable to the understanding of a melody.

(It is interesting to observe that the pictures which come before our minds when we read an isolated word and try to understand it correctly just like that are commonly altogether absent when we read a sentence; the picture that comes before our minds when we read a sentence with understanding is often something like a resultant of the whole sentence).

38 It is possible for a person to forget the meaning of a word (e.g. "blue"). What has he forgotten?--How is that manifested?

He may point, for instance, to a chart of different colours and say "I don't know any longer which of these is called 'blue'". Or again, he may not any longer know at all what the word means (what purpose it serves); he may know only that it is an English word.

We might say: if someone has forgotten the meaning of the word "blue" and is asked to choose a blue object from among others he feels as he looks at the objects that the connection between the word "blue" and the colour no longer holds but has been broken off. The connection will be reestablished, it might be said, if we repeat the definition of the word for him. But we might reestablish the connection in various ways: we might point to a blue object and say "that is blue", or say "remember your blue

patch" or we perhaps utter the German word "blau", etc. etc. And if I now say there are these different ways in which we can establish the connection this suggests there's a single particular phenomenon I call the connection

between word and colour, or the understanding of the word, a phenomenon I've produced in all these different ways, just as I can use objects of different shapes and materials as conductors to connect the ends of two wires. But there is no need for such a phenomenon of connection, no need, say, that when I hear the word a picture of the colour should occur before my inner eye. For if what is reestablished in his understanding of the word, this can manifest itself in very various processes. There isn't a further process hidden behind, which is the real understanding, accompanying and causing these manifestations in the way that toothache causes one to groan, hold one's cheek, pull faces, etc. If I am now asked if I think that there's no such thing as understanding but only manifestations of understanding, I must answer that this question is as senseless as the question whether there is a number three. I can only describe piecemeal the grammar of the word "understand" and point out that it differs from what one is inclined to portray without looking closely. We are like the little painter Klecksel who drew two eyes in a man's profile, since he knew that human beings have two eyes.

Page 80

39 The effect of an explanation of the meaning of a word is like 'knowing how to go on', when you recite the beginning of a poem to someone until he says "now I know how to go on". (Tell yourself the various psychological forms this knowing how to go on may take.)

Page 80

The way in which language was learnt is not *contained* in its use. (Any more than the cause is contained in the effect.)

Page 80

How does an ostensive definition work? Is it put to work again

Page Break 81

every time the word is used, or is it like a vaccination which changes us once and for all?

Page 81

A definition as a part of the calculus cannot act at a distance. It acts only by being applied.

Page 81

40 Once more: in what cases shall we say that the man understands the word "blue"? Well, if he picks out a blue object from others on demand; or if he credibly says that he could now pick out the blue object but doesn't want to (perhaps we notice that while he says this he glances involuntarily at the blue object; perhaps we believe him simply on account of his previous behaviour). And how does *he* know that he understands the word? i.e. in what circumstances will *he* be able to say it? Sometimes after some kind of test, but sometimes also without. But in that case won't he sometimes have to say later "I was wrong, I did not understand it after all" if it turns out that he can't apply it? Can he justify himself in such cases by saying that he did indeed understand the word when he said he did, but that the meaning later slipped his memory? Well, what can he offer as a criterion (proof) that he did understand the word at the previous time?--Perhaps he says "At that time I saw the colour in my mind's eye, but now I can't remember it." Well, if that implies that he understood it, he did understand it then.--Or he says: "I can only say I've used the word a hundred times before", or "I'd used it just before, and while I was saying I understood it I was thinking of that occasion." It is what is regarded as the justification of an assertion that constitutes the sense of the assertion.

Page 81

Suppose we say "he understands the word 'blue', he picked the blue ball out from the others right away" and then he says "I just picked it out by guesswork, I didn't understand the word". What sort of criterion did he have for not having understood the word? Ought we to believe him? If one asks oneself "How do I know that

Page Break 82

I don't understand this word" it produces a very strange thought sensation. One wants to say "I don't connect anything with it", "it says nothing to me", "It's a mere noise", and in order to understand these utterances one has to call to mind what it's like "when one connects something with a word", when a definition has made the sound into a meaningful word, when one can *do something* with the word.

Page 82

You will say: "But he certainly can't be wrong when he says that he didn't understand the word." And that is an observation about the grammar of the statement "I didn't understand the word". It is also an observation about grammar when we say, "Whether he understood, is something he knows which we cannot *know* but only guess". Moreover the statement "I didn't understand the word" doesn't describe a state at the time of hearing the word; there are many different ways in which the processes characteristic of not understanding may have taken place later.

Page 82

41 We speak of understanding (a process of understanding, and also a state of understanding) and also of certain

processes which are criteria for this understanding.

Page 82

We are inclined to call understanding a mental process or a state of mind. This characterizes it as a *hypothetical* process etc., or rather as a process (or state) in the sense of a hypothesis. That is, we banish the word "understanding" to a particular region of grammar.

Page 82

The grammar of a mental state or process is indeed in many respects similar to that of e.g. a brain-process. The principal difference is perhaps that in the case of a brain-process a direct check is admitted to be possible; the process in question may perhaps be seen by opening the skull. But there is no room for a similar "immediate perception" in the grammar of mental process. (There is no such move in this game.)

Page Break 83

Page 83

What is the criterion for our understanding the word "red"? That we pick out a red object from others on demand, or that we can give the ostensive definition of the word "red"?

Page 83

We regard both things as signs of understanding. If we hear someone use the word "red" and are in doubt whether he understands it, we can check by asking: "which colour do you call red?" On the other hand, if we'd given someone the ostensive definition of the word and then wanted to see whether he'd understood it rightly, we wouldn't ask him to repeat it, but we would set him a task like picking out the red objects from a row.

Page 83

Here it can be asked: "are we talking about *my* understanding or other people's understanding?"

Page 83

"Only I can know whether I understand, others can only guess." "He understands' is a hypothesis; 'I understand' is not."

Page 83

If that's what we say, then we're conceiving "understanding" as an experience, analogous e.g. to a pain.

Page 83

People say: "You cannot know whether I understand (whether I am glad), etc.; you can't look inside me." "You can't know what I think." Yes, but that's so only as long as you don't think aloud; and we aren't interested here in the difference between thinking out loud (or in writing) and thinking in the imagination.

Page 83

Here you may object that thinking is after all private even if it is only the *visual* experience of writing, and that though another person can see what my physical hand is writing he cannot have my visual experience. These questions must occupy us in another place.

Page 83

But for our present purpose can't we say "he is writing" and "I am writing" instead of "he understands" and "I understand?"

Page 83

Then we leave the question of experience *completely* out of the

Page Break 84

game. Also, for instance, the question of private understanding. For then it appears unimportant here.

Page 84

What we call "understanding" is not the behaviour--whatever it may be--that shows us the understanding, but a state of which this behaviour is a sign. And that is a statement about the grammar of denoting such a state.

Page 84

42 We might call the recital of the rules on its own a criterion for understanding, or alternatively tests of use on their own. Then in the one case "he understands" would mean: "if you ask him for for [[sic]] the rules, he will tell you them"; in the other case "if you require him to apply the rule, he will carry out your order".

Page 84

Or we may regard the recital of the rules as a symptom of the man's being able to do something other than recite the rules. As when I hold a watch to my ear, hear it ticking and say: it is going. In that case I don't just expect it to go on ticking, but also to show the time.

Page 84

One might say: "The recital of the rules is a criterion of understanding, if the man recites them with understanding and not purely mechanically." But here once again an intelligent intonation during the recitation can

count as understanding; and so why not the recitation itself?

Page 84

To understand is to grasp, to receive a particular impression from an object, to let it work on one. To let a proposition work on one; to consider consequences of the proposition, to imagine them, etc.

Page 84

What we call "understanding" is a psychological phenomenon that has a special connection with the phenomena of learning and using our human language.

Page 84

What happens when I remember the meaning of a word? I see before me an object of a certain colour and I say "this book is

Page Break 85

brown and I have always called this colour 'brown'. What sort of act of remembering must take place for me to be able to say that? This question could be put in a much more general form. For instance, if someone asked me "have you ever before seen the table at which you are now sitting?" I would answer "yes, I have seen it countless times". And if I were pressed I would say "I have sat at it every day for months".--What act or acts of remembering occur in such a case? After all I don't see myself in my mind's eye "sitting at this table every day for months". And yet I say that I remember that I've done so, and I can later corroborate it in various ways. Last summer too, for example, I was living in this room. But how do I know that? Do I see it in my mind's eye? No. In this case what does the remembering consist of? If I as it were hunt for the basis of the memory, isolated pictures of my earlier sojourn surface in my mind; but even so they don't have, say, a date written into them. And even before they've surfaced and before I've called any particular evidence into my mind, I can say truly that I remember that I lived here for months and saw this table. Remembering, then, isn't at all the mental process that one imagines at first sight. If I say, rightly, "I remember it" the most *varied* things may happen; perhaps even just that I say it. And when I here say "rightly" of course I'm not laying down what the right and wrong use of the expression is; on the contrary I'm just describing the actual use.

Page 85

The psychological process of understanding is in the same case as the arithmetical object Three. The word "process" in the one case, and the word "object" in the other produce a false grammatical *attitude* to the word.

Page 85

43 Isn't it like this? First of all, people use an explanation, a chart, by looking it up; later they as it were look it up in the head (by calling it before the inner eye, or the like) and finally they work

Page Break 86

without the chart, as if it had never existed. In this last case they are playing a different game. For it isn't as if the chart is still in the background, to fall back on; it is excluded from our game, and if I "fall back on it" I am like a blinded man falling back on the sense of touch. An explanation provides a chart and when I no longer use the chart it becomes mere history.

Page 86

I must distinguish between the case in which I follow the table, and the case in which I behave in accordance with the table without making use of it.--The rule we learnt which makes us now behave in such and such a way is of no interest to us considered as the cause or history behind our present behaviour.--But as a general description of our manner of behaving it is a hypothesis. It is the hypothesis that the two people who sit at the chess board will behave (move) in such and such a manner. (Here even a breach of the rules falls under the hypothesis, since it says something about the behaviour of the players when they become aware of the breach). But the players might also use the rules by looking up in each particular case what is to be done; here the rule would enter into the conduct of the game itself and would not be related to it as hypothesis to confirmation. But there is a difficulty here. For a player who plays without using the list of rules, and indeed has never seen one, might nevertheless if asked give the rules of his game--not by ascertaining through repeated observation what he does in such and such a position in the game, but by superintending a move and saying "in such a case *this is how one moves*".--But, if that is so, that just shows that in certain circumstances he can enunciate the rules, not that he makes explicit use of them while playing.

Page 86

It is a hypothesis that he will if asked recite a list of rules; if a disposition or capacity for this is postulated in him, it is a psychological disposition analogous to a physiological one. If it is said

Page Break 87

that this disposition characterizes the process of playing, it characterizes it as the psychological or physiological one

it really is. (In our study of symbolism there is no foreground and background; it isn't a matter of a tangible sign with an accompanying intangible power or understanding.)

Page 87

44 What interests *us* in the sign, the meaning which matters for us is what is embodied in the grammar of the sign.

Page 87

We ask "How do you use the word, what do you do with it"--that will tell us how you understand it.

Page 87

Grammar is the account books of language. They must show the actual transactions of language, everything that is not a matter of accompanying sensations.

Page 87

In a certain sense one might say that we are not concerned with nuances.

Page 87

(I could imagine a philosopher who thought that he must have a proposition about the essence of knowing printed in red, otherwise it would not really express what it was meant to express.)

Page Break 88

IV

Page 88

45 The interpretation of written and spoken signs by ostensive definitions is not an *application* of language, but part of the grammar. The interpretation remains at the level of generality preparatory to any application.

Page 88

The ostensive definition may be regarded as a rule for translating from a gesture language into a word language. If I say "the colour of this object is called 'violet'", I must already have denoted the colour, already presented it for christening, with the words "the colour of that object" if the naming is to be able to take place. For I might also say "the name of this colour is for you to decide" and the man who gives the name would in that case already have to know what he is to name (where in the language he is stationing the name).

Page 88

That one empirical proposition is true and another false is no part of grammar. What belongs to grammar are all the conditions (the method) necessary for comparing the proposition with reality. That is, all the conditions necessary for the understanding (of the sense).

Page 88

In so far as the meaning of words becomes clear in the fulfilment of an expectation, in the satisfaction of a wish, in the carrying out of an order etc., it already shows itself when we put the expectation into language. It is therefore completely determined in the grammar, in what could be foreseen and spoken of already before the occurrence of the event.

Page 88

46 Does our language consist of primary signs (ostensive gestures) and secondary signs (words)? One is inclined to ask, whether it isn't the case that our language *has* to have primary signs while it could get by without the secondary ones.

Page 88

The false note in this question is that it expects an explanation of

Page Break 89

existing language instead of a mere description.

Page 89

It sounds like a ridiculous truism to say that a man who thinks that gestures are the primitive signs underlying all others would not be able to replace an ordinary sentence by gestures.

Page 89

One is inclined to make a distinction between rules of grammar that set up "a connection between language and reality" and those that do not. A rule of the first kind is "this colour is called 'red'",--a rule of the second kind is " $\sim\sim p = p$ ". With regard to this distinction there is a common error; language is not something that is first given a structure and then fitted on to reality.

Page 89

One might wish to ask: So is it an accident that in order to define signs and complete the sign-system I have to go outside the written and spoken signs? When I do that don't I go right into the realm where what is to be described occurs?--But in that case isn't it strange that I can do anything at all with the written signs?--We say perhaps that the written signs are mere representatives of the things the ostensive definition points to.--But how then

is this representing possible? I can't after all make just anything stand in for anything else.--It is indeed important that such representing is possible; for the representative must, in certain cases at least, do the job as well as the principal.

Page 89

47 We say that something like a red label is the primary sign for the colour red, and the word is a secondary sign, because the meaning of the word "red" is explained if I point, etc. to a red label, but not if I say "red" means the same as "rouge". But don't I explain the meaning of the word "red" to a Frenchman in just this way? "Yes, but only because he has learnt the meaning of 'rouge' by *ostensive* definition". But if he understands my explanation "red =

Page Break 90

rouge" does he have to have this definition--or a red image--present to his mind? If not, it is mere history. Must he have such a picture present whenever we would say he was using the word "rouge" with understanding? (Think of the order: "Imagine a round red patch.")

Page 90

48 Are the signs one wants to call 'primary' incapable of being misinterpreted?

Page 90

Can one perhaps say, they don't really any longer need to be *understood*?--If that means that they don't have to be further *interpreted*, that goes for words too; if it means, they *cannot* be further interpreted, then it's false. (Think of the explanation of gestures by words and vice versa).

Page 90

Is it correct, and if so in what sense, to say that the ostensive definition is like the verbal definition in replacing one sign by another--the pointing by the word?

Page 90

49 Suppose I lay down a method of designation. Suppose, for example, I want to give names to shades of colours for my private use. I may do so by means of a chart; and of course I won't write a name beside a wrong colour (beside a colour I don't want to give that name to). But why not? Why shouldn't "red" go beside the green label and "green" beside the red, etc.? If the ostensive definition merely replaces one sign by another, that shouldn't make any difference.--Here there are at any rate two different possibilities. It may be that the table with green beside "red" is used in such a way that a man who 'looks it up' goes diagonally from the word "red" to the red label, and from the word "green" to the green one and so on. We would then say that though the table was arranged differently (had a different spatial scheme) it connected the signs in the same way as the usual one.--But it might also be that the person using the table looks from one side horizontally to another, and in some sentences uses a green label instead of the word "red", and yet obeys an order like "give me a

Page Break 91

red book" not by bringing a green book, but perfectly correctly by bringing a red one (i.e. one that we too would call "red"). Such a man would have used the table in a different way from the first, but still in such a way that the word "red" means the same colour for him as it does for us.

Page 91

Now it is the second case which interests us, and the question is can a green label be a *sample* of red?--

Page 91

I can imagine an arrangement according to which a man to whom I show a green label with the words "paint me this colour" is to paint me red and if I show him blue with the same words, is to paint me yellow (always the complementary colour). And someone might interpret my order in that way even without such a convention. The convention might also have been "if I say, 'paint this colour', then always paint one slightly darker", and again we could imagine the order being thus interpreted even without this prearrangement.--But can it be said that when someone is painting a certain shade of green he is *copying* the red of the label--as he may copy a geometrical figure according to various methods of projection, copying it in different but equally exact ways?--Can I compare colours with shapes? Can a green label be used both as the name of a particular shade of red, and also as a sample of it just as a circle can serve as the name of a particular elliptical shape, and also as a sample for it?

Page 91

It is clear that a sample is not used like a word (a name). And an ostensive definition, a table, which leads us from words to samples, is used differently from a table which replaces one name by another.

Page 91

50 However, the word "copy" has different meanings in different cases and what I mean by "pattern" changes correspondingly. What does "to copy a figure exactly" mean? Does it mean copy it exactly with the unaided eye? Or with measuring instruments, and if so which? What shall we be willing to call the same colour as that of the pattern?

Think of various methods of comparison. How far is the rule to copy darker comparable to a rule to copy a figure

Page Break 92

on a larger, or small scale?

Page 92

Imagine a man who claimed to be able to copy shades of red into green, who fixed his eye on a red sample and with every outward sign of exact copying mixed a shade of green. For us he would be on a par with someone who listened carefully and mixed colours in accordance with notes on a violin. In such a case we'd say "I don't know *how* he does it"; not because we didn't understand the processes in his brain or in his muscles, but because we don't understand what is meant by "this shade of colour is a copy of this note on the violin". Unless that means that as a matter of experience a man associates a particular shade of colour with a particular note (sees it in his mind's eye, paints it etc). The difference between the meanings of "associate" and "copy" shows itself in the fact that it doesn't make sense to speak of a projection-method (rule of translation) for association. We say: "you haven't copied correctly", but not "you haven't associated correctly".

Page 92

On the other hand it is certainly conceivable that human beings might agree so exactly with each other in associating colours with violin notes that one might say to another: "No, you haven't represented that violin note correctly, it was yellower than you painted it" and the other would answer something like "you're right, the same thought occurred to me".

Page 92

51 If the table connects the word with a sample, then it isn't indifferent which label the word is linked with when the table is consulted--"So then there are signs that are arbitrary and signs that are not!" Compare the giving of information by maps and drawings, with the giving of information by sentences. The sentences are no more arbitrary than the drawings are; only the words are arbitrary. On the other hand the projection of the maps is arbitrary; and how would you decide which of the two is the more arbitrary?

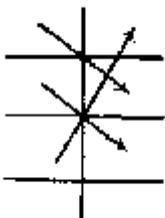

Page Break 93

Page 93

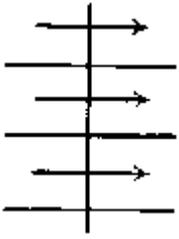

Certainly I can compare deciding on the meanings of words with deciding on a method of projection, such as that for the representation of spatial forms ("the proposition is a picture"). That is a good comparison, but it doesn't exempt us from investigating the way words signify, which has its own rules. We can of course say--that is, it accords with usage--that we communicate by signs whether we use words or patterns, but the game of acting in accordance with words is not the same game as acting in accordance with patterns. (Words are not essential to what we call "language", and neither are samples). Word-language is only one of many possible kinds of language, and there are transitions between one kind and another. (Think of two ways of writing the proposition "I see a red circle": it might be done by writing a circle and giving it the appropriate colour (red), or by writing a circle with a red patch beside it. Consider what corresponds in a map to the form of expression of a word-language.)

Page 93

52 "I won't insist that the red pattern in the explanatory chart must be horizontally opposite the word 'red', but there must be some sort of law for reading the table or it will lose its sense." But is there no law if the chart is read in the way indicated by the arrows of the following schema?

"But in that case *mustn't* this schema of arrows be given in advance?"--Well, must you give this schema before we follow the normal use?

Page Break 94

Page 94

"But in that case mustn't there at least be a regularity through time in the use of the table? Would it work if we were to use the table in accordance with different schemata at different times? *How would one know* in that case how the table was to be used?" Well, how does one know *anyway*? Explanations of signs come to an end somewhere.

Page 94

Of course if I showed someone the way by pointing my finger not in the direction in which he was to go, but in the opposite direction, in the absence of a special arrangement I should cause a misunderstanding. It is part of human nature to understand pointing with the finger in the way we do. (As it is also part of human nature to play board games and to use sign languages that consist of written signs on a flat surface.)

Page 94

The chart doesn't guarantee that I shall pass from one part of it to another in a uniform manner. It doesn't compel me to use it always in the same way. It's there, like a field, with paths leading through it: but I can also cut across.--Each time I apply the chart I make a fresh transition. The transitions aren't made as it were once for all in the chart (the chart merely suggests to me that I make them).

Page 94

(What kind of propositions are these?--They are like the observation that explanations of signs come to an end somewhere. And that is rather like saying "How does it help you to postulate a creator, it only pushes back the problem of the beginning of the world." This observation brings out an aspect of my explanation that I perhaps hadn't noticed. One might also say: "Look at your explanation in *this* way--now are you still satisfied with it?")

Page 94

53 Is the word "red" enough to enable one to look for something red? Does one need a memory image to do so?

Page 94

Can one say that the word "red" needs a supplement in memory in order to be a usable sign?

Page 94

If I use the words "there is a red book in front of me" to describe an experience, is the justification of the choice of these words,

Page Break 95

apart from the experience described, the fact that I remember that I've always used the word "red" for this colour? Does that *have to* be the justification?

Page 95

In order to be able to *[[sic]]* obey a spoken order do we need something like a memory picture of what we did when we last obeyed it?

Page 95

So is the real order "Do now what you remember doing then"? This order too might be given. But does that mean that in order to obey it, I need a memory image of searching my memory?

Page 95

The order "do now what you remember doing then" tells me that I am to look in a particular place for a picture that will tell me what I am to do. So the order is very similar to "Do what is written on the piece of paper in this drawer". If there is nothing on the piece of paper then the order lacks sense.

Page 95

If the use of the word "red" depends on the picture that my memory automatically reproduces at the sound of this word, then I am as much at mercy of this reproduction as if I had decided to settle the meaning by looking up a chart in such a way that I would surrender unconditionally to whatever I found there.

Page 95

If the sample I am to work with appears darker than I remember it being yesterday, I need not agree with the memory and in fact I do not always do so. And I might very well speak of a darkening of my memory.

54 If I tell someone "paint from memory the colour of the door of your room" that doesn't settle what he is to do any more unambiguously than the order "paint the green you see on this chart". Here too it is imaginable that the first of the sentences might be understood in the way one would normally understand a sentence

like "paint a colour somewhat lighter than the one you remember seeing there". On the other hand the man ordered to paint the shade of colour in accordance with the sample will usually be in no doubt about the method of projection.

If I'm told: "look for a red flower in this meadow and bring it to me" and then I find one--do I compare it with my memory picture of the colour red?--And must I consult yet another picture to see whether the first is still correct?--In that case why should I need the first one?--I see the colour of the flower and recognize *it*. (It would naturally be *conceivable* that someone should hallucinate a colour sample and compare it, like a real sample, with the object he was looking for.)

But if I say "no, this colour isn't the right one, it's brighter than the colour I saw there" that doesn't mean that I see the colour in my mind's eye and go through a process of comparing two simultaneously given shades of colour. Again, it isn't as if when the right colour is found a bell rings somewhere in my mind and I carry round a picture of this ringing, so as to be able to judge when it rings.

Searching with a sample which one places beside objects to test whether the colours match is one game; acting in accordance with the words of a word-language without a sample is another. Think of reading aloud from a written text (or writing to dictation). We might of course imagine a kind of table that might guide us in this; but in fact there isn't one, there's no act of memory, or anything else, which acts as an intermediary between the written sign and the sound.

55 Suppose I am now asked "why do you choose *this* colour when given this order; how do you justify the choice?" In the one case I can answer "because *this* colour is opposite the word 'red' in my chart." In the other case there is no answer to the question and the question makes no sense. But in the first game there is no sense in *this* question: "why do you call 'red' the colour in the chart

opposite the word 'red'"? A *reason* can only be given *within* a game. The links of the chain of reasons come to an end, at the boundary of the game. (Reason and cause.)

If one calls to mind "that the chart does not compel us" to use it in a particular way, or even always to use it in the same way, it becomes clear to everyone that our use of the words "rule" and "game" is a fluctuating one (blurred at the edges).

The connection between "language and reality" is made by definitions of words, and these belong to grammar, so that language remains self-contained and autonomous.

56 Imagine a gesture language used to communicate with people who have no word-language in common with us. Do we feel there too the need to go outside the language to explain its signs?

"The connection between words and things is set up by the teaching of language." What kind or sort of connection is this? A mechanical, electrical, psychological connection is something which may or may not function. *Mechanism and Calculus*.

The correlation between objects and names is simply the one set up by a chart, by ostensive gestures and simultaneous uttering of the name etc. It is a part of the symbolism. Giving an object a name is essentially the same kind of thing as hanging a label on it.

It gives the wrong idea if you say that the connection between name and object is a psychological one.

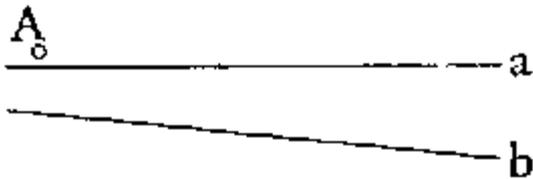

57 Imagine someone copying a figure on the scale of 1 to 10. Is the understanding of the general rule of such mapping contained in the process of copying?--The pencil in my hand was free from

Page Break 98

presuppositions, so to speak, and was guided (influenced) only by the length of the lines in the pattern.--I would say that if the pattern had been longer, I should have drawn my pencil further and if it had been shorter, not so far. But is the mind which thus expresses itself already contained in the copying of the line?

Page 98

Suppose I want to meet someone on the street. I can decide "I will go on until I find N"--and then go along the street and stop when I meet him at a particular point. Did the process of walking, or some other simultaneous process, include acting in accordance with the general rule I intended? Or was what I did only *in agreement* with that rule, but also in agreement with other rules?

Page 98

I give someone the order to draw from A a line parallel to a. He tries (intends) to do it, but with the result that the line is parallel to b. Was what happened when he copied the same as if he had intended to draw a line parallel to b and carried out his intention?

Page 98

If I *succeed* in reproducing a paradigm in accordance with a prescribed rule, is it possible to use a different general rule to describe the process of copying, the way it took place? Or can I reject such a description with the words "No, I was guided by *this* rule, and not by the other, though admittedly in this case the other would have given the same result"?

Page 98

58 One is inclined to say: If I intentionally copy a shape, then the process of copying has the shape in common with the pattern. The form is a facet of the process of copying; a facet which fits the copied object and coincides with it there.

Page Break 99

Page 99

Even if my pencil doesn't do justice to the model, my intention always does.

Page 99

If I intend to play the piano from written music, it is experience that will show which notes I actually play and the description of what is played need not have anything in common with the written notes. But if I want to describe my *intention*, the description must be that I wanted to reproduce *these* written notes in sounds.--That alone can be the expression of the fact that intention reaches up to the paradigm and contains a general rule.

Page 99

An expression of intention describes the model to be copied; describing the copy does not.

Page 99

59 For the purposes of our studies it can never be essential that a symbolic phenomenon occurs in the mind and not on paper so that others can see it. One is constantly tempted to explain a symbolic process by a special psychological process; as if the mind "could do much more in these matters" than signs can.

Page 99

We are misled by the idea of a mechanism that works in special media and so can explain special movements. As when we say: this movement can't be explained by any arrangement of levers.

Page 99

A *description* of what is psychological must be something which can itself be used as a symbol.

Page 99

A connected point is that an explanation of a sign can replace the sign itself. This gives an important insight into the nature of the explanation of signs, and brings out a contrast between the idea of this sort of explanation and that of causal explanation.

Page 99

60 It could be said that it can't be decided by outward observation whether I am *reading* or merely producing sounds while a text runs before my eyes. But what is of interest to us in reading can't be essentially something *internal*. Deriving a translation from the

Page Break 100

original may also be a visible process. For instance, it must be possible to regard as a derivation what takes place on paper when the terms of the series 100, 121, 144, 169 are derived from the terms of the series 10, 11, 12, 13 by the following calculations

$$\begin{array}{r} 10 \times 10 \\ \hline 100 \end{array}, \quad \begin{array}{r} 11 \times 11 \\ \hline 121 \end{array}, \quad \begin{array}{r} 12 \times 12 \\ \hline 144 \end{array}, \quad \begin{array}{r} 13 \times 13 \\ \hline 169 \end{array}$$

Page 100

(The distinction between "inner" and "outer" does not interest us.)

Page 100

Every such more or less behaviourist account leaves one with the feeling that it is crude and heavy handed; but this is misleading we are tempted to look for a "better" account, but there isn't one. One is as good as the other and in each case what represents is the *system* in which a sign is used.--("Representation is dynamic, not static.")

Page 100

(Even a psychological process cannot "leave anything open" in any way essentially different from the way in which an empty bracket in the symbolism leaves open an argument place.)

Page 100

One may not ask "What sort of thing are mental processes, since they can be true and false, and non-mental ones cannot?" For, if the 'mental' ones can, then the others must be able to do as well and vice versa.--For, if the mental processes can, their descriptions must be able to as well. For how this is possible must show itself in their descriptions.

Page 100

If one says that thought is a mental activity, or an activity of the mind, one thinks of the mind as a cloudy gaseous medium in which many things can happen which cannot occur in a different sphere, and from which many things can be expected that are otherwise not possible.

Page 100

(The process of thinking in the human mind, and the process of digestion).

Page Break 101

Page 101

61 Every case of copying (acting *in obedience to*, not just in accordance with, particular rules), every case of *deriving* an action from a command or justifying an action by a command, is the same kind of thing as writing down the steps that lead to the answer of a sum, or pointing to signs standing beside each other in a table.

x	1	2	3	4
x ²				16
x ³				64

Page 101

"I write the number '16' here *because* it says 'x²' there, and '64' here because it says x³ there." That is what every justification looks like. In a certain sense it takes us no further. But indeed it can't take us *further* i.e. into the realm of metalogic.

Page 101

(The difficulty here is: in not trying to justify what admits of no justification.)

Page 101

Suppose, though, I said "I write a '+' here because it says 'x²' there? You would ask "Do you always write a '+'

where it says "x²"?--that is, you would look for a general rule; otherwise the "because" in my sentence makes no sense. Or you might ask "So how do you know that *that* is why you wrote it?"

Page 101

In that case you've taken the "because" as introducing a statement of the cause, instead of the reason.

Page 101

If I write "16" under "4" in accordance with the rule, it might appear that some causality was operating that was not a matter of hypothesis, but something immediately perceived (experienced).

Page 101

(Confusion between 'reason' and 'cause'.)

Page 101

What connection do I mean in the sentence "I am going out, *because* he's telling me to"? And how is this sentence related to "I am going out, *although* he told me to". (Or "I am going out, but not because he told me to" "I am going out, because he told me not to".)

Page Break 102

V

Page 102

62 "That's *him*" (this picture represents *him*)--that contains the whole problem of representation.

Page 102

What is the criterion, how is it to be verified, that this picture is the portrait of that object, i.e. that it is *meant* to represent it? It is not similarity that makes the picture a portrait (it might be a striking resemblance of one person, and yet be a portrait of someone else it resembles less).

Page 102

How can I know that someone means the picture as a portrait of N?--Well, perhaps because he says so, or writes it underneath.

Page 102

What is the connection between the portrait of N and N himself? Perhaps, that the name written underneath is the name used to address him.

Page 102

When I remember my friend and see him "in my mind's eye", what is the connection between the memory image and its subject? The likeness between them?

Page 102

Well, the image, *qua picture*, can't do more than resemble him.

Page 102

The image of him is an unpainted portrait.

Page 102

In the case of the image too, I have to write his name under the picture to make it the image of him.

Page 102

I have the intention of carrying out a particular task and I make a plan. The plan in my mind is supposed to consist in my seeing myself acting thus and so. But how do I know, that it is myself that I'm seeing? Well, it isn't myself, but a kind of a picture. But why do I call it the picture of *me*?

Page 102

"How do I know that it's myself?": the question makes sense if it means, for example, "how do I know that I'm the one I see there". And the answer mentions characteristics by which I can be recognized.

Page 102

But it is my own decision that makes my image represent myself. And I might as well ask "how do I know that the word 'I' stands for myself?" For my shape in the picture was only another word "I".

Page Break 103

Page 103

"I can imagine your being about to go out of the door." We suffer from a strange delusion that in the proposition, the thought, the objects do what the proposition states about them. It's as though the command contained a shadow of the execution. But a shadow of just *this* execution. It is *you* in the command who go to such and such a place.--Otherwise it would be just a *different* command.

Page 103

This identity is indeed the identity contrasted with the diversity of two different commands.

Page 103

"I thought Napoleon was crowned in the year 1805."--What has your thought got to do with Napoleon?--What connection is there between your thought and Napoleon?--It may be, for example, that the word "Napoleon" occurs in the expression of my thought, plus the connection that word had with its bearer; e.g. that was the way he signed his name, that was how he was spoken to and so on.

Page 103

"But when you utter the word 'Napoleon' you designate that man and no other"--"How then does this act of designating work, in your view? Is it instantaneous? Or does it take time?"--"But after all if someone asks you 'did you mean the very man who won the battle of Austerlitz' you will say 'yes'. So you meant that man *when you uttered the sentence*."--Yes, but only in the kind of way that I then knew also that $6 \times 6 = 36$.

Page 103

The answer "I meant the victor of Austerlitz" is a new step in our calculus. The past tense is deceptive, because it looks as if it was giving a description of what went on "inside me" while I was uttering the sentence.

Page 103

("But I meant *him*". A strange process, this meaning! Can you mean in Europe someone who's in America? Even if he no longer exists?)

Page 103

63 Misled by our grammar, we are tempted to ask "*How* does one think a proposition, *how* does one expect such and such to happen? (how does one do that?)"

Page Break 104

Page 104

"How does thought work, how does it use its expression?"--This question looks like "How does a Jacquard loom work, how does it use the cards".

Page 104

In the proposition "I believe that p is the case" we feel that the essential thing, the real process of belief, isn't expressed but only hinted at; we feel it must be possible to replace this hint by a description of the mechanism of belief, a description in which the series of words "p" would occur as the cards occur in the description of the loom. This description, we feel, would be at last the full expression of the thought.

Page 104

Let's compare belief with the utterance of a sentence; there too very complicated processes take place in the larynx, the speech muscles, the nerves, etc. These are *accompaniments* of the spoken sentence. And the sentence itself remains the only thing that interests us--not as part of a mechanism, but as part of a calculus.

Page 104

"How does thought manage to represent?"--the answer might be "Don't you really know? You certainly see it when you think." For nothing is concealed.

Page 104

How does a sentence do it? Nothing is hidden.

Page 104

But given this answer "But you know how sentences do it, for nothing is concealed" one would like to say "yes, but it all goes by so quick, and I should like to see it as it were laid open to view".

Page 104

We feel that thoughts are like a landscape that we have seen and are supposed to describe, but don't remember exactly enough to describe how all the parts fitted together. Similarly, we think, we can't describe thought after the event because then the many delicate processes have been lost sight of. We would like as it were to see these intricacies under the magnifying glass. (Think of the proposition "Everything is in flux".)

Page Break 105

Page 105

We ask: "What is a thought? What kind of thing must something be to perform the function of thought?" This question is like: "What is a sewing machine, how does it work?"--And the answer which would be like ours would be "Look at the stitch it is meant to sew; you can see from that what is essential in the machine, everything else is optional."

Page 105

So what is the function, that makes thought what it is?--

Page 105

If it is its *effect*, then we are not interested in it.

Page 105

We are not in the realm of causal explanations, and every such explanation sounds trivial for our purposes.

Page 105

64 If one thinks of thought as something specifically human and organic, one is inclined to ask "could there be a prosthetic apparatus for thinking, an inorganic substitute for thought?" But if thinking consists only in writing or speaking, why shouldn't a machine do it? "Yes, but the machine doesn't know anything." Certainly it is senseless to talk of a prosthetic substitute for seeing and hearing. We do talk of artificial feet, but not of artificial pains in the foot.

Page 105

"But could a machine think?"--Could it be in pain?--Here the important thing is what one means by something *being in pain*. I can look on another person--another person's *body*--as a machine which is in pain. And so, of course, I can in the case of my own body. On the other hand, the phenomenon of pain which I describe when I say something like "I have toothache" doesn't presuppose a physical body. (I can have toothache without teeth.) And in this case there is no room for the machine.--It is clear that the machine can only replace a physical body. And in the sense in which we can say of such a body that it is in pain, we can say it of a machine as well. Or again, what we can compare with machines and call machines is the *bodies* we say are in pain.

Page Break 106

Page 106

In the consideration of our problems one of the most dangerous ideas is the idea that we think *with*, or *in*, *our heads*.

Page 106

The idea of a process in the head, in a completely enclosed space, makes thinking something occult.†1

Page 106

"Thinking takes place in the head" really means only "the head is connected with thinking".--Of course one says also "I think with my pen" and this localisation is at least as good.

Page 106

It is a travesty of the truth to say "Thinking is an activity of our mind, as writing is an activity of the hand". (Love in the heart. The head and the heart as loci of the soul).

Page 106

65 We may say "Thinking is operating with symbols". But 'thinking' is a fluid concept, and what 'operating with symbols' is must be looked at separately in each individual case.

Page 106

I might also say "Thinking is operating with language" but 'language' is a fluid concept.

Page 106

It is correct to say "Thinking is a mental process" only if we also call seeing a written sentence or hearing a spoken one a mental process. In the sense, that is, in which pain is called a mental state. In that case the expression "mental process" is intended to distinguish 'experience' from 'physical processes'.--On the other hand, of course, the expression "mental process" suggests that we are concerned with imperfectly understood processes in an inaccessible sphere.

Page 106

Psychology too talks of 'unconscious thought' and here "thought" means a process in a mind-model. ('Model' in the sense in which one speaks of a mechanical model of electrical processes).

Page 106

By contrast, when Frege speaks of the thought a sentence expresses the word "thought" is more or less equivalent to the expression "sense of the sentence".

Page Break 107

Page 107

It might be said: in every case what is meant by "thought" is the *living* element in the sentence, without which it is dead, a mere succession of sounds or series of written shapes.

Page 107

But if I talked in the same way about a something that gives meaning to an arrangement of chessmen, something that makes it different from an arbitrary collection of bits of wood, I might mean almost anything! I might mean the rules that make the arrangement of chessmen a position in a game, or the special experiences we connect with positions in the game or the use of the game.

Page 107

It is the same if we speak of a something that makes the difference between paper money and mere printed

bits of paper, something that gives it its meaning, its life.

Page 107

Though we speak of a thought and its expression, the thought is not a kind of condition that the sentence produces as a potion might. And communication by language is not a process by which I use a drug to produce in others the same pains as I have myself.

Page 107

(What sort of process might be called "thought-transference" or "thought-reading"?)

Page 107

66 A French politician once said it was a special characteristic of the French language that in French sentences words occurred in the sequence in which one thinks them.

Page 107

The idea that one language in contrast to others has a word order which corresponds to the order of thinking arises from the notion that thought is an essentially different process going on independently of the expression of the thoughts.

Page 107

(No one would ask whether the written multiplication of two numbers in the decimal system runs parallel with the thought of the multiplication.)

Page 107

"I meant something definite by it, when I said..."

Page 107

--"Did you mean something different when you said each word, or did you mean the same thing throughout the whole sentence?"

Page Break 108

Page 108

It is strange, though: you can mean something by each word and the combination of them can still be nonsense!

Page 108

"At the time when you said the sentence, did you think of the fact that..."

Page 108

"I thought only what I said."

Page 108

(It perplexes us that there is no moment at which the thought of a sentence is completely present. Here we see that we are comparing the thought with a thing that we manufacture and possess as a whole; but in fact as soon as one part comes into being another disappears. This leaves us in some way unsatisfied, since we are misled by a plausible simile into expecting something different.)

Page 108

Does the child learn only to talk, or also to think? Does it learn the sense of multiplication *before* or *after* it learns multiplication?

Page 108

Is it, as it were, a contamination of the sense that we express it in a particular language which has accidental features, and not as it were bodiless and pure?

Page 108

Do I really not play chess itself because the chessmen might have had a different shape?

Page 108

(Is a mathematical proof in the general theory of irrational numbers less general or rigorous because we go through it using the decimal notation for those numbers? Does it impair the rigour and purity of the proposition $25 \times 25 = 625$ that it is written down in a particular number system?)

Page 108

Thought can only be something common-or-garden and *ordinary*. (We are accustomed to thinking of it as something ethereal and unexplored, as if we were dealing with something whose exterior alone is known to us, and whose interior is yet unknown like our brain.) One is inclined to say: "Thought, what a strange thing!" But when I say that thought is something quite common-or-garden, I mean that we are affected by this concept as we are by a concept like that of the number one. There seems to be something mysterious about it, because we misunderstand its grammar and feel the lack of a tangible substance

Page Break 109

to correspond to the substantive. (It is almost like hearing a human voice coming from in front of us, and seeing nobody there.)

Page 109

67 What does man think for? What use is it? Why does he *calculate* the thickness of the walls of a boiler and not leave it to chance or whim to decide? After all it is a mere fact of experience that boilers do not explode so often if made according to calculations. But just as having once been burnt he would do anything rather than put his hand into the fire, so he would do anything rather than not calculate for a boiler.--Since we are not interested in causes, we might say: human beings do in fact think: this, for instance, is how they proceed when they make a boiler.--Now, can't a boiler produced in this way explode? Certainly it can.

Page 109

We think over our actions before we do them. We make pictures of them--but why? After all, there is no such thing as a "thought-experiment".

Page 109

We expect something, and act in accordance with the expectation; must the expectation come true? No. Then why do we act in accordance with the expectation? Because we are impelled to, as we are impelled to get out of the way of a car, to sit down when we are tired, to jump up if we have sat on a thorn.

Page 109

What the thought of the uniformity of nature amounts to can perhaps be seen most clearly when we fear the event we expect. Nothing could induce me to put my hand into a flame--although after all it is *only in the past* that I have burnt myself.

Page 109

The belief that fire will burn me is of the same nature as the fear that it will burn me.

Page 109

Here I see also what "it is certain" means.

Page 109

If someone pushed me into the fire, I would struggle and go on

Page Break 110

resisting; and similarly I would cry out "it will burn me!" and not "perhaps it will be quite agreeable".

Page 110

"But after all you do believe that more boilers would explode if people did not calculate when making boilers!" Yes, I believe it;--but what does that mean? Does it follow that there will in fact be fewer explosions?--Then what is the foundation of this belief?

Page 110

68 I assume that his house in which I am writing won't collapse during the next half hour.--When do I assume this? The whole time? And what sort of an activity is this assuming?

Page 110

Perhaps what is meant is a psychological disposition; or perhaps the thinking and expressing of particular thoughts. In the second case perhaps I utter a sentence which is part of a train of thought (a calculation). Now someone says: you must surely have a reason to assume that, otherwise the assumption is unsupported and worthless.--(Remember that we stand on the earth, but the earth doesn't stand on anything else; children think it'll have to fall if it's not supported). Well, I do have reasons for my assumption. Perhaps that the house has already stood for years, but not so long that it may already be rickety, etc. etc.--*What* counts as a reason for an assumption can be given *a priori* and determines a calculus, a system of transitions. But if we are asked now for a reason for the calculus itself, we see that there is none.

Page 110

So is the calculus something we adopt arbitrarily? No more so than the fear of fire, or the fear of a raging man coming at us.

Page 110

"Surely the rules of grammar by which we act and operate are not arbitrary!" Very well; why then does a man think in the way he does, why does he go through these activities of thought? (This question of course asks for reasons, not for causes.) Well, reasons can be given within the calculus, and at the very end one is tempted to say "it just is very probable, that things will behave in this case as they always have"--or something similar. A turn of

Page Break 111

phrase which masks the beginning of the chain of reasons. (The creator as the explanation at the beginning of the world).†1

The thing that's so difficult to understand can be expressed like this. *As long as* we remain in the province of the true-false games a change in the grammar can only lead us from *one* such game to another, and never from something true to something false. On the other hand if we go outside the province of these games, we don't any longer call it 'language' and 'grammar', and once again we don't come into contradiction with reality.

VI

69 What is a proposition?--What am I distinguishing a proposition from? What do I want to distinguish it from? From things which are only parts of propositions in the same grammatical system (like the parts of an equation)? Or from everything we don't call propositions, including this chair and my watch, etc. etc?

The question "how is the general concept of proposition bounded?" must be countered with another: "Well, do we have a *single* concept of proposition?"

"But surely I have a definite concept of what I mean by 'proposition'." Well, and how would I explain it to another or to myself? This explanation will make clear what my concept is (I am not concerned with a feeling accompanying the word 'proposition'). I would explain the concept by means of examples.--So my concept goes as far as the examples.--But after all they're only examples, and their range is capable of extension.--All right, but in that case you must tell me what "capable of extension" means here. The grammar of this word must have definite boundaries.

"But I know a proposition when I see one, so I must also be able to draw the boundaries of the concept precisely." But is it really the case that no doubt is possible?--Imagine a language in which all sentences are commands to go in a particular direction. (This language might be used by a primitive kind of human beings exclusively in war. Remember how restricted the use of written language once was.) Well, we would still call the commands "come here", "go there", "sentences". †1 But suppose now the language consisted only in pointing the finger in one direction or the other.--Would this sign still be a proposition?--And what about a language like the early speech of children whose signs expressed only desire for particular objects, a language which consisted simply of signs for these objects (of nouns, as it were)? Or consider

a system consisting of two signs, one expressing acceptance and the other rejection of proffered objects. Is this a language, does it consist of propositions?

And on the other hand: does everything that sounds like a sentence in English fall under our concept of *proposition*? "I am tired", " $2 \times 2 = 4$ ", "time passes", "there is only one zero"?

The word "proposition" does not signify a sharply bounded concept. If we want to put a concept with sharp boundaries beside our use of this word, we are free to define it, just as we are free to narrow down the meaning of the primitive measure of length "a pace" to 75 cm.

70 "What happens when a new proposition is taken into the language: what is the criterion for its being a proposition?" Let us imagine such a case. We become acquainted with a new experience, say the tingling of an electric shock, and we say it's unpleasant. What right have I to call this newly formed statement a "proposition"? Well, what right did I have to speak of a new "experience", or a new "muscular sensation"? Surely I did so by analogy with my earlier use of these words. But, on the other hand, did I *have* to use the word "experience" and the word "proposition" in the new case? Do I already assert something about the sensation of the electric shock when I call it an experience? And what difference would it make if I excluded the statement "the tingling is unpleasant" from the concept of proposition, because I had already drawn its boundaries once and for all?

Compare the concept of proposition with the concept 'number' and then with the concept of cardinal number. We count as numbers cardinal numbers, rational numbers, irrational numbers, complex numbers; whether we call other constructions numbers because of their similarities with these, or draw a definitive boundary here or

elsewhere, depends on us. In this respect the concept of number is like the concept of proposition. On the

Page Break 114

other hand the concept of cardinal number $[1, \xi, \xi + 1]$ can be called a rigorously circumscribed concept, that's to say it's a concept in a different sense of the word.

Page 114

71 How did I come by the concept 'proposition' or the concept 'language'? Only through the languages I've learnt.--But in a certain sense they seem to have led me beyond themselves, since I'm now able to construct a new language, for instance to invent words.--So this construction too belongs to the concept of language. But only if I so stipulate. The sense of my "etc." is constantly given limits by its grammar.

Page 114

That's also what I meant when I said "there are surprises in reality but not in grammar."

Page 114

"But language can expand"--Certainly; but if this word "expand" has a sense here, then I know *already* what I mean by it. I must be able to specify how I imagine such an expansion. And what I can't think, I can't now express or even hint at. And in *this* case the word "now" means: "in this calculus" or "if the words are used according to *these* grammatical rules".

Page 114

But here we also have this nagging problem: how is it possible even to *think* of the existence of things when we always see only images, copies of them?--We ask: "Then how did I come by this concept at all?" It would be quite correct to add in thought the rider: "It is not as if I was able to transcend my own thought", "It is not as if I could sensibly transcend what has sense for me." We feel that there is no way of smuggling in by the back door a thought I am barred from thinking directly.

Page 114

No sign leads us beyond itself, and no argument either.

Page Break 115

Page 115

What does a man do when he constructs (invents) a new language; on what principle does he operate? For this principle is the concept of 'language'. Does every newly constructed language broaden (alter) the concept of language?--Consider its relationship to the earlier concept: that depends on how the earlier concept was established.--Think of the relation of complex numbers to the earlier concept of number; and again of the relation of a *new* multiplication to the general concept of the multiplication of cardinal numbers, when two particular (perhaps very large) cardinal numbers are written down for the first time and multiplied together.

Page 115

72 In logic one cannot employ generality in a void. If I determine the grammar of my generality, then there are no more surprises in logic. And if I do not determine it, then I am no longer in the realm of an exact grammar.

Page 115

That's to say, the indeterminacy of generality is not a logical indeterminacy. Generality is a freedom of movement, not an indeterminacy of geometry.

Page 115

But if the general concept of language dissolves in this way, doesn't philosophy dissolve as well? No, for the task of philosophy is not to create a new, ideal language, but to clarify the use of our language, the existing language. Its aim is to remove particular misunderstandings; not to produce a real understanding for the first time.

Page 115

If a man points out that a word is used with several different meanings, or that a certain misleading picture comes to mind when we use a certain expression, if he sets out (tabulates) rules according to which certain words are used, he hasn't committed himself to giving an explanation (definition) of the words "rule", "proposition", "word", etc.

Page 115

I'm allowed to use the word "rule" without first tabulating the rules for the use of the word. And those rules are not super-rules.

Page Break 116

Page 116

Philosophy is concerned with calculi in the same sense as it is concerned with thoughts, sentences and languages. But if it was really concerned with the concept of calculus, and thus with the concept of the calculus of all

calculi, there would be such a thing as metaphilosophy. (But there is not. We might so present all that we have to say that this would appear as a leading principle.)

Page 116

73 How do we use the word "rule", say when we are talking of games? In contrast to what?--We say for instance "that follows from this rule", but in that case we could cite the rule in question and thus avoid the word "rule". Or we speak of "all the rules of a game" and in that case either we've listed them (in which case we have a repetition of the first case) or we're speaking of the rules as a group of expressions produced in a certain way from given basic rules, and then the word "rule" stands for the expression of *those* basic rules and operations. Or we say "*this* is a rule and *that* isn't"--if the second, say, is only an individual word or a sentence which is incomplete by the standards of English grammar, or the illustration of a position of pieces in a game. (Or "No, according to the new convention that too is a rule"). If we had to write down the list of rules of the game, something like that might be said and then it would mean "*this* belongs in it and *that* doesn't". But this isn't on the strength of a particular property, the property of being a rule, like the case when one wants to pack only apples in a box and says, "no, that shouldn't go in there, that's a pear".

Page 116

Yes, but there are many things we call games and many we don't, many things we call rules and many we don't!--But it's never a question of drawing a boundary between everything we call games and everything else. For us games are *the* games of which we have heard, the games we can list, and perhaps some others newly devised by analogy; and if someone wrote a book on games, he wouldn't really need to use the word "game" in the title of the book, he could use as a title a list of the names of the individual games.

Page Break 117

Page 117

If he's asked "but what's *common* to all these things that makes you collect them together?" he might say: I can't give it straight off--but surely you may see many analogies. Anyway the question seems to me idle, because proceeding by analogy, I can also come by imperceptible steps to things that no one in ordinary life would any longer call "games". Hence I call games things on this list, and whatever is similar to these games up to a certain point that I don't further specify. Moreover, I reserve the right to decide in every new case whether I will count something as a game or not.

Page 117

The case is the same with the concepts 'rule', 'proposition', 'language', etc. It is only in special cases (i.e. not every time we use the word "rule") that it is a question of drawing a boundary between rules and what are not rules, and in all cases it is easy to give the distinguishing mark. We use the word "rule" in contrast to "word", "projection" and some other words and these demarcations can be clearly drawn. On the other hand we commonly do not draw boundaries where we do not need them. (Just as in certain games a single line is drawn in the middle of the field to separate the sides, but the field is not otherwise bounded since it is unnecessary.)

Page 117

We are able to use the word "plant" in a way that gives rise to no misunderstanding, yet countless borderline cases can be constructed in which no one has yet decided whether something still falls under the concept 'plant'. Does this mean that the meaning of the word "plant" in all other cases is infected by uncertainty, so that it might be said we use the word without understanding it? Would a definition which bounded this concept on several sides make the meaning of the word clearer to us in *all* sentences? Would we understand better all the sentences in which it occurs?

Page 117

74 How did we learn to understand the word "plant", then? Perhaps we learnt a definition of the concept, say in botany, but I leave out that of account since it only has a role in botany. Apart

Page Break 118

from that, it is clear that we learnt the meaning of the word by example; and if we disregard hypothetical dispositions, these examples stand only for themselves. Hypotheses about learning and using language and causal connections don't interest us. So we don't assume that the examples produce something in the learner, that they set before his mind an essence, the meaning of the concept-word, the concept 'plant'. If the examples should have an effect, say they produce a particular visual picture in the learner, the causal connection between the examples and this picture does not concern us, and for us they are merely *coincidental*. So we can perhaps disregard the examples altogether and look on the picture alone as a symbol of the concept; or the picture and the examples together.

Page 118

If someone says "we understand the word 'chair', since we know what is common to all chairs"--what does it

mean to say we *know* that? That we are ready to say it (like "we know that 6×6 is 36")? What is it that is common, then? Isn't it only because we can apply the word "chair" that we say here we know what is common? Suppose I explained the word "red" by pointing to a red wall, a red book, and a red cloth and in accordance with this explanation someone produced a sample of the colour red by exhibiting a red label. One might say in this case that he had shown that he had grasped the common element in all the examples I gave him. Isn't it an analogy like this that misleads us in the case of "chair"?

Page 118

The grammatical place of the words "game", "rule", etc. is given by examples in rather the way in which the place of a meeting is specified by saying that it will take place *beside* such and such a tree.

Page 118

75 One imagines the meaning as something which *comes before* our minds when we hear a word.

Page 118

What comes before our minds when we hear a word is certainly something characteristic of the meaning. But what comes before

Page Break 119

my mind is an example, an application of the word. And this coming to mind doesn't really consist in a particular image's being present whenever I utter or hear the word, but in fact that when I'm asked the meaning of the word, applications of the word *occur* to me.

Page 119

Someone says to me: "Shew the children a game" I teach them gaming with a dice, and the other says "I didn't mean that sort of game". Must the exclusion of the game with dice have come before his mind when he gave me the order?

Page 119

Suppose someone said: "No. I didn't mean that sort of game; I used 'game' in the narrower sense." How does it come out, that he used the word in the narrower sense?

Page 119

But can't one also use the word "game" in its broadest sense? But which is that? No boundaries have been drawn unless we fix some on purpose.

Page 119

If we found a sentence like "The Assyrians knew various games" in a history book without further qualifications, it would strike us as very curious; for we wouldn't be certain that we could give an example that even roughly corresponded to the meaning of the word "game" in this case.

Page 119

Someone wants to include in the list of rules of a game the proposition that the game was invented in such and such a year. I say "No, that doesn't belong to the list of rules, that's not a rule." So I'm excluding historical propositions from the rules. And similarly I would exclude from the rules, as an empirical proposition, a proposition like "this game can only be learnt by long practice". But it could easily be misleading to say boundaries had thereby been drawn around the area of rules.

Page 119

76 If I try to make clear to someone by characteristic examples

Page Break 120

the use of a word like "wish", it is quite likely that the other will adduce as an objection to the examples I offered another one that suggests a different type of use. My answer then is that the new example may be useful in discussion, but isn't an objection to my examples. For I didn't want to say that those examples gave the essence of what one calls "wishing". At most they present different essences which are all signified by this word because of certain inter-relationships. The error is to suppose that we wanted the examples to illustrate the essence of wishing, and that the counter examples showed that this essence hadn't yet been correctly grasped. That is, as if our aim were to give a theory of wishing, which would have to explain every single case of wishing.

Page 120

But for this reason, the examples given are only useful if they are clearly worked out and not just vaguely hinted at.

Page 120

The use of the words "proposition", "language", etc. has the haziness of the normal use of concept-words in our language. To think this makes them unusable, or ill-adapted to their purpose, would be like wanting to say "the warmth this stove gives is no use, because you can't feel where it begins and where it ends".

If I wish to draw sharp boundaries to clear up or avoid misunderstandings in the area of a particular use of language, these will be related to the fluctuating boundaries of the natural use of language in the same way as sharp contours in a pen-and-ink sketch are related to the gradual transitions between patches of colour in the reality depicted.

Socrates pulls up the pupil who when asked what knowledge is enumerates cases of knowledge. And Socrates doesn't regard that as even a preliminary step to answering the question.

But our answer consists in giving such an emuneration and a

few analogies. (In a certain sense we are always making things easier and easier for ourselves in philosophy.)

77 The philosophy of logic speaks of sentences and words in exactly the sense in which we speak of them in ordinary life when we say "Here is a Chinese sentence", or "No, that only looks like writing; it is actually just an ornament" and so on.

We are talking about the spatial and temporal phenomenon of language, not about some non-spatial, non-temporal phantasm. But we talk about it as we do about the pieces in chess when we are stating the rules of the game, not describing their physical properties.

The question "what is a word?" is analogous to "What is a piece in chess (say the king)?"

In reflecting on language and meaning we can easily get into a position where we think that in philosophy we are not talking of words and sentences in a quite common-or-garden sense, but in a sublimated and abstract sense.--As if a particular proposition wasn't really the thing that some person utters, but an ideal entity (the "class of all synonymous sentences" or the like). But is the chess king that the rules of chess deal with such an ideal and abstract entity too?

(We are not justified in having any more scruples about our language than the chess player has about chess, namely none.)

Again, we cannot achieve any greater generality in philosophy than in what we say in life and in science. Here too (as in mathematics) we leave everything as it is.

When I talk about language (words, sentences, etc.) I must speak the language of every day. Is this language somehow too coarse and material for what we want to say? Then how is another one to be constructed?--And how strange that we should be able to do anything at all with the one we have!

In giving philosophical explanations about language I already have to use language full-blown (not some sort of preparatory, provisional one); this by itself shows that I can adduce only exterior facts about language.

"Yes, but then how can these explanations satisfy us?"--Well, your very questions were framed in this language!--And your scruples are misunderstandings. Your questions refer to words, so I have to talk about words.

You say: the point isn't the word, but its meaning, and you think of the meaning as a thing of the same kind as the word, though also different from the word. Here the word, there the meaning. The money, and the cow that you can buy with it. (But contrast: money, and its use).

78 If we ask about the general form of proposition--bear in mind that in normal language sentences have a particular rhythm and sound but we don't call everything 'that sounds like a sentence' a sentence.--Hence we speak also of significant and non-significant "sentences".

On the other hand, sounding like a sentence in this way isn't essential to what we call a proposition in logic.

The expression "sugar good" doesn't sound like an English sentence, but it may very well replace the proposition "sugar tastes good". And not e.g. in such a way that we should have to add in thought something that is missing. (Rather, all that matters is the system of expressions to which the expression "sugar good" belongs.)

Page 122

So the question arises whether if we disregard this misleading business of sounding like a sentence we still have a general concept of proposition.

Page 122

Imagine the English language altered in such a way that the order of the words in a sentence is the reverse of the present one. The result would be the series of words which we get if we read sentences of an English book from right to left. It's clear that the multiplicity of possible ways of expression in this language must be exactly the same as in English; but if a longish sentence were read thus we could understand it only with great difficulty and we'd

Page Break 123

perhaps never learn "to think in this language". (The example of such a language can make clear a lot about the nature of what we call "thought".)

Page 123

79 The definition "A proposition is whatever can be true or false" fixes the concept of proposition in a particular language system as what in that system can be an argument of a truth-function.

Page 123

And if we speak of what makes a proposition a proposition, we are inclined to mean the truth-functions.

Page 123

"A proposition is whatever can be true or false" means the same as "a proposition is whatever can be denied".

"p" is true = p

"p" is false = $\sim p$

What he says is true = Things are as he says.

Page 123

One might say: the words "true" and "false" are only items in a particular notation for truth-functions.

Page 123

So is it correct to write "'p' is true", "'p' is false"; mustn't it be "p is true" (or false)? The ink mark is after all not *true*; in the way in which it's black and curved.

Page 123

Does "'p' is true" state anything about the sign "p" then? "Yes, it says that 'p' agrees with reality." Instead of a sentence of our word language consider a drawing that can be compared with reality according to exact projection-rules. This surely must show as clearly as possible what "'p' is true" states about the picture "p". The proposition "'p' is true" can thus be compared with the proposition "this object is as long as this metre rule" and "p" to the proposition "this object is one metre long". But the comparison is incorrect, because "this metre rule" is a description, whereas "metre rule" is the determination of a concept. On the other hand in "'p' is true" the ruler enters immediately into the proposition. "p" represents here simply the length and not the metre rule. For the representing drawing is also not 'true' except in accordance

Page Break 124

with a particular method of projection which makes the ruler a purely geometrical appendage of the measured line.

Page 124

It can also be put thus: The proposition "'p' is true" can only be understood if one understands the grammar of the sign "p" as a propositional sign; not if "p" is simply the name of the shape of a particular ink mark. In the end one can say that the quotation marks in the sentence "'p' is true" are simply superfluous.

Page 124

If one explains: "(x).fx" is true, if "f()" gives true sentences for all substitutions--we must reflect that the sentence "(x).fx" follows from the proposition 'f()' gives true sentences for all substitutions", and *vice versa*. So the two propositions say the same.

Page 124

So that explanation does not assemble the mechanism of generality from its parts.

Page 124

One can't of course say that a proposition is whatever one can predicate "true" or "false" of, as if one could put symbols together with the words "true" and "false" by way of experiment to see whether the result makes sense. For something could only be decided by this experiment if "true" and "false" already have definite meanings, and

they can only have that if the contexts in which they can occur are already settled.--(Think also of identifying parts of speech by questions. "Who or what...?")

Page 124

80 In the schema "This is how things stand" the "how things stand" is really a handle for the truth-functions.

Page 124

"Things stand", then, is an expression from a notation for truth-functions. An expression which shows us what part of grammar comes into play here.

Page 124

If I let "that is how things stand" count as the general form of proposition, then I must count " $2 + 2 = 4$ " as a proposition. Further rules are needed if we are to exclude the propositions of arithmetic.

Page Break 125

Page 125

Can one give the *general form of a proposition*?--Why not? In the same way as one might give the general form of a number, for example by the sign " $|0, \xi, \xi + 1|$ ". I am free to restrict the name "number" to *that*, and in the same way I can give an analogous formula for the construction of propositions or laws and use the word "proposition" or "law" as equivalent to that formula.--If someone objects and says that this will only demarcate certain laws from others, I reply: of course you can't draw a boundary if you've decided in advance not to recognize one. But of course the question remains: how do you use the word "proposition"? In contrast to what?

Page 125

("Can a proposition treat of all propositions, or all propositional functions?" What is meant by that? Are you thinking of a proposition of logic?--What does the proof of such a proposition look like?)

Page 125

A general propositional form determines a proposition as part of a calculus.

Page 125

81 Are the rules that say that such and such a combination of words yields no sense comparable to the stipulations in chess that the game does not allow two pieces to stand on the same square, for instance, or a piece to stand on a line between two squares? Those propositions in their turn are like certain actions; like e.g. cutting a chess board out of a larger sheet of squared paper. They draw a boundary.

Page 125

So what does it mean to say "this combination of words has no sense"? One can say of a name (of a succession of sounds): "I haven't given anyone this name"; and name-giving is a definite action (attaching a label). Think of the representation of an explorer's route by a line drawn in each of the two hemispheres projected on the page: we may say that a bit of line going outside the circles on the page makes no sense in this projection. We might also express it thus: no stipulation has been made about it.

Page Break 126

Page 126

"How do I manage always to use a word significantly? Do I always look up the grammar? No, the fact that I mean something,--what I mean prevents me from talking nonsense."--But what do I mean?--I would like to say: I speak of bits of an apple, but not bits of the colour red, because in connection with the words "bits of an apple", unlike the expression "bits of the colour red", I can imagine something, picture something, want something. It would be more correct to say that I *do* imagine, picture, or want something in connection with the words "bits of an apple" but not in connection [[sic]] with the expression "bits of the colour red".

Page 126

But the expression "I'm cutting red into bits" can have a sense (e.g. the sense of the proposition "I'm cutting something red into bits").--Suppose I asked: which word is it, which mistake, that makes the expression senseless? This shows that this expression, in spite of its senselessness, makes us think of a quite definite grammatical system. That's why we also say "red can't be cut into bits" and so give an answer; whereas one wouldn't make any answer to a combination of words like "is has good". But if one is thinking of a particular system, a language game plus its application, then what is meant by "'I'm cutting red into bits' is senseless" is first and foremost that this expression doesn't belong to the particular game its appearance makes it seem to belong to.

Page 126

If we do give a sense to the set of words "I'm cutting red into bits" how do we do it?--We can indeed turn it into quite different things; an empirical proposition, a proposition of arithmetic (like $2 + 2 = 4$), an unproved theorem of mathematics (like Goldbach's conjecture), an exclamation, and other things. So I've a free choice: how is it bounded? That's hard to say--by various types of utility, and by the expression's formal similarity to certain primitive

forms of proposition; and all these boundaries are blurred.

Page 126

"How do I know that the colour red can't be cut into bits?" That isn't a question either.

Page 126

I would like to say: "I must *begin* with the distinction between

Page Break 127

sense and nonsense. Nothing is possible prior to that. I can't give it a foundation."

Page 127

82 Can one ask: "How must we make the grammatical rules for words if they are to give a sentence sense"?

Page 127

I say, for instance: There isn't a book here, but there could be one; on the other hand it's nonsensical to say that the colours green and red could be in a single place at the same time. But if what gives a proposition sense is its agreement with grammatical rules then let's make just this rule, to permit the sentence "red and green are both at this point at the same time". Very well; but that doesn't fix the grammar of the expression. Further stipulations have yet to be made about how such a sentence is to be used; e.g. how it is to be verified.

Page 127

If a proposition is conceived as a picture of the state of affairs it describes and a proposition is said to show just how things stand if it's true, and thus to show the possibility of the asserted state of affairs, still the most that the proposition can do is what a painting or relief does: and so it can at any rate not set forth what is just not the case. So it depends wholly on our grammar what will be called possible and what not, i.e. what that grammar permits. But surely that is arbitrary! Certainly; but the grammatical constructions we call empirical propositions (e.g. ones which describe a visible distribution of objects in space and could be replaced by a representational drawing) have a particular application, a particular use. And a construction may have a superficial resemblance to such an empirical proposition and play a somewhat similar role in a calculus without having an analogous application; and if it hasn't we won't be inclined to call it a proposition.

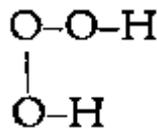

Page 127

"Possible" here means the same as "conceivable"; but "conceivable" may mean "capable of being painted", "capable of being modelled", "capable of being imagined"; i.e. representable

Page Break 128

in a particular system of propositions. What matters is the system.--For example someone asks: "is it conceivable that a row of trees might go on forever in the same direction without coming to an end?" Why shouldn't it be 'conceivable'? After all it's expressible in a grammatical system. But if so what's the application of the proposition? How is it verified? What is the relation between its verification and the verification of a proposition like "this row of trees ends at the hundredth tree"? That will tell us how much this conceivability is worth, so to speak.

Page 128

Chemically possible

†1

Page 128

"I haven't ever in fact seen a black line gradually getting lighter until it was white, and then more reddish until it was red: but I know that it is possible, because I can imagine it." The form of expression "I know that it is possible, because..." is taken from cases like "I know that it is possible to unlock the door with this key, because I once did so". So am I making *that* sort of conjecture: that the colour transition will be possible since I can imagine it?--Isn't this rather the way it is: here "the colour transition is possible" has the same meaning as "I can imagine it?" What about *this*: "The alphabet *can* be said aloud, *because* I can recite it in my mind"?

Page 128

"I can imagine the colour transition" isn't an assertion here about a particular power of my own imagination, in the way that "I can lift this stone" is about the power of my own muscles. The sentence "I can imagine the transition", like "this state of affairs can be drawn", connects the linguistic representation with another form of representation; it is to be understood as a proposition of grammar.

Page 128

83 It looks as if we could say: Word-language allows of senseless combination of words, but the language of imagining does not

allow us to imagine anything senseless. Hence too the language of drawing doesn't allow of senseless drawings.--But that isn't how it is: for a drawing can be senseless in the same way as a proposition. Think of a blueprint from which a turner is to work; here it is very easy to represent an exact analogy with a senseless pseudo-proposition. Remember too the example of drawing a route on a projection of the globe.

When one wants to show the senselessness of metaphysical turns of phrase, one often says "I couldn't imagine the opposite of that", or "What would it be like if it were otherwise?" (When, for instance, someone has said that my images are private, that only I alone can know if I am feeling pain, etc.) Well, if I can't imagine how it might be otherwise, I equally can't imagine that it is *so*. For here "I can't imagine" doesn't indicate a lack of imaginative power. I can't even *try* to imagine it; it makes no sense to say "I imagine it". And that means, no connection has been made between this sentence and the method of representation by imagination (or by drawing).

But why does one say "I can't imagine how it could be *otherwise*" and not "I can't imagine the thing itself"? One regards the senseless sentence (e.g. "this rod has a length") as a tautology as opposed to a contradiction. One says as it were: "Yes, it has a length; but how could it be otherwise; and why say so?" To the proposition "This rod has a length" we respond not "Nonsense!" but "Of course!" We might also put it thus: when we hear the two propositions, "This rod has a length" and its negation "This rod has no length", we take sides and favour the first sentence, instead of declaring them both nonsense. But this partiality is based on a confusion: we regard the first proposition as verified (and the second as falsified) by the fact "that the rod has a length of 4 metres". "After all, 4 metres is a length"--but one forgets that this is a grammatical proposition.

It is often possible to show that a proposition is meant metaphysically by asking "Is what you affirm meant to be an empirical proposition? Can you conceive (imagine) its being otherwise?"--Do you mean that substance has never yet been destroyed, or that it is *inconceivable* that it should be destroyed? Do you mean that experience shows that human beings always prefer the pleasant to the unpleasant?

How strange that one should be able to say that such and such a state of affairs is inconceivable! If we regard thought as essentially an accompaniment going with an expression, the words in the statement that specify the inconceivable state of affairs must be unaccompanied. So what sort of sense is it to have? Unless it says these words are senseless. But it isn't as it were their sense that is senseless; they are excluded from our language like some arbitrary noise, and the reason for their *explicit* exclusion can only be that *we are tempted* to confuse them with a sentence of our language.

84 The role of a sentence in the calculus is its sense.

A *method* of measurement--of length, for example--has exactly the same relation to the correctness of a statement of length as the sense of a sentence has to its truth or falsehood.

What does "discovering that an assertion doesn't make sense" mean?--and what does it mean to say: "If I mean something by it, surely it must make sense to say it"? "If I mean something by it"--if I mean *what* by it?--

One wants to say: a significant sentence is one which one can not merely say, but also think. But that would be like saying: a significant picture is one that can not merely be drawn but also represented plastically [[sic]]. And saying this would make sense. But the thinking of a sentence is not an activity which one does from the words (like singing from a score). The following example shews this.

Does it make sense to say "The number of my friends is equal to a root of the equation $x^2 + 2x - 3 = 0$?" Here, one might think,

we have a notation whose grammar doesn't settle by itself whether a sentence makes sense or not, so that it wasn't determined in advance. That is a fine example of what is meant by understanding a proposition.

If the expression "the root of the equation..." were a Russellian description, then the proposition "I have n apples and $2 + n = 6$ " would have a different sense from the proposition "I have 4 apples".

Page 131

The sense of a proposition (or atthought) isn't anything spiritual; it's what is given as an answer to a request for an explanation of the sense. Or: one sense differs from another in the same way as the explanation of the one differs from the explanation of the other. So also: the sense of one proposition differs from the sense of another in the same way as the one proposition differs from the other.

Page 131

The sense of a proposition is not a soul.

Page 131

It is only in a language that something is a proposition. To understand a proposition is to understand a language.

Page 131

A proposition is a sign in a system of signs. It is *one* combination of signs among a number of possible ones, and as opposed to other possible ones. As it were *one* position of an indicator as opposed to other possible ones.

Page 131

"Go in the direction the arrow points."

"Go a hundred times as far as the arrow is long."

"Go as many paces as I draw arrows."

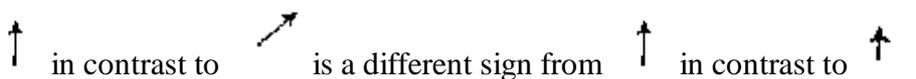

"Draw a copy of this arrow."

"Come at the time shown by this arrow considered as the hour hand of a clock."

Page 131

For all of these commands the same arrow might do.

Page 131

 in contrast to  is a different sign from  in contrast to  .

Page Break 132

VII

Page 132

85 Symbols appear to be of their nature unsatisfied.

Page 132

Wishes, conjectures, beliefs, commands appear to be something unsatisfied, something in need of completion. Thus I would like to characterize my feeling of grasping a command as a feeling of an innervation. But the innervation in itself isn't anything unsatisfied, it doesn't leave anything open, or stand in need of completion.

Page 132

And I want to say: "A wish is unsatisfied because it's a wish *for something*; opinion is unsatisfied, because it's the opinion that something is the case, something real, something outside the process of opining."

Page 132

I would like to say: "my expectation is so made that whatever happens has to accord with it or not".

Page 132

The proposition seems set over us as a judge and we feel answerable to it.--It seems to demand that reality be compared with it.

Page 132

I said that a proposition was laid against reality like a ruler. And a ruler--like all logical comparisons for a proposition--is itself in a particular case a propositional sign. Now one would like to say: "Put the ruler against a body: it does not say that the body is of such-and-such a length. Rather it is in itself dead and achieves nothing of what thought achieves." It is as if we had imagined that the essential thing about a living being was the outward form. Then we made a lump of wood in that form, and were abashed to see the stupid block, which hasn't even any similarity to life.

Page 132

86 I want to say: "if someone could see the process of expectation, he would necessarily be seeing what was expected."--But that is the case: if you see the expression of an expectation you see what is being expected. And in what other way, in what other sense would it be possible to see it?

Page Break 133

Page 133

When we give an order, it can look as if the ultimate thing sought by the order had to remain unexpressed, as there is always a gulf between an order and its execution. Say I want someone to make a particular movement, say to raise his arm. To make it quite clear, I do the movement. This picture seems unambiguous till we ask: how does he know that *he is to make that movement?*--How does he know at all what use he is to make of the signs I give him, whatever they are? Perhaps I shall now try to supplement the order by means of further signs, by pointing from myself to him, making encouraging gestures etc. Here it looks as if the order were beginning to stammer.

Page 133

Suppose I wanted to tell someone to square the number 4, and did so by means of the schema:

x	4
x ²	?

Page 133

Now I'm tempted to say that the question mark only hints at something it doesn't express.

Page 133

As if the sign were precariously trying to produce understanding in us. But if we now understand it, by what token do we understand?

Page 133

The appearance of the awkwardness of the sign in getting its meaning across, like a dumb person who uses all sorts of suggestive gestures--this disappears when we remember that the sign does its job only in a grammatical system.

Page 133

(In logic what is unnecessary is also *useless*.)

Page 133

87 In what sense can one call wishes as such, beliefs, expectations etc. 'unsatisfied'? What is the prototype of nonsatisfaction from which we take our concept? Is it a hollow space? And would one call that unsatisfied? Wouldn't this be a metaphor too? Isn't what we call nonsatisfaction a feeling--say hunger?

Page Break 134

Page 134

In a particular system of expressions we can describe an object by means of the words "satisfied" and "unsatisfied". For example, if we lay it down that we call a hollow cylinder an "unsatisfied cylinder" and the solid cylinder that fills it its "satisfaction".

Page 134

It seems as if the expectation and the fact satisfying the expectation fitted together somehow. Now one would like to describe an expectation and a fact which fit together, so as to see what this agreement consists in. Here one thinks at once of the fitting of a solid into a corresponding hollow. But when one wants to describe these two one sees that, to the extent that they fit, a *single* description holds for both. (On the other hand compare the meaning of: "These trousers don't go with this jacket"!)

Page 134

Expectation is not related to its satisfaction in the same way as hunger is related to its satisfaction. I can describe the hunger, and describe what takes it away, and say that it takes it away. And it isn't like this either: I have a wish for an apple, and so I will call 'an apple' whatever takes away the wish.

Page 134

88 The strange thing is expressed in the fact that if this is the event I expected, it isn't distinct from the one I expected.

Page 134

I say: "that's just how I imagined it"; and someone says something like "That's impossible, because the one was an image and the other isn't. Did you take your image for reality?"

Page 134

I see someone pointing a gun and say "I expect a report". The shot is fired.--Well, that was what you expected, so did that bang somehow already exist in your expectation? Or is it just that there is some other kind of agreement between your expectation and what occurred; that that noise was not contained in your expectation and merely accidentally supervened when the expectation was being fulfilled? But no, if the noise had not occurred, my expectation

would not have been fulfilled; the noise fulfilled it; it was not an accompaniment of the fulfilment like a second guest accompanying the one I expected.--Was the thing about the event that was not in the expectation too an accident, an extra provided by fate?--But then what was *not* an extra? Did something of the shot already occur in my expectation?--Then what was extra? for wasn't I expecting the whole shot?

"The report was not so loud as I had expected." "Then was there a louder bang in your expectation?"

"The red which you imagine is surely not the same (the same thing) as the red which you see in front of you; so how can you say that it is what you imagined?"--But haven't we an analogous case with the propositions "Here is a red patch" and "Here there isn't a red patch"? The word "red" occurs in both; so this word cannot indicate the presence of something red. The word "red" does its job only in the propositional context. Doesn't the misunderstanding consist in taking the meaning of the word "red" as being the sense of a sentence saying that something is red?

The possibility of this misunderstanding is also contained in the ambiguity of expressions like "the colour red as the common element of two states of affairs"--This may mean that in each something *is* red, has the colour red; or else that both propositions are about the colour red.

What is common in the latter case is the harmony between reality and thought to which indeed a form of our language corresponds.

89 If we say to someone "imagine the colour red" he is to imagine a patch or something that is red, not one that is green, since that is *not red*.

(Could one define the word "red" by pointing to something that was *not red*? That would be as if one were supposed to explain

the word "modest" to someone whose English was weak, and one pointed to an arrogant man and said "That man is *not* modest". That it is ambiguous is no argument against such a method of definition. Any definition can be misunderstood. But it might well be asked: are we still to call this "definition"?--For, of course, even if it has the same practical consequences, the same *effect* on the learner, it plays a different part in the calculus from what we ordinarily call "ostensive definition" of the word "red".)

It would be odd to say: "A process looks different when it happens from when it doesn't happen." Or "a red patch looks different when it is there from when it isn't there; but language abstracts from this *difference*, for it speaks of a red patch whether it is there or not."

Reality is not a property still missing in what is expected and which accedes to it when one's expectation is fulfilled.--Nor is reality like the daylight that things need to acquire colour, when they are already there, as it were colourless, in the dark.

"How do you know that you are expecting *a* red patch; that is, how do you know that a red patch is the fulfilment of your expectation?" But I might just as well ask: "how do you know that that *is* a red patch?"

How do you know that what you did really was to recite the alphabet in your head?--But how do you know that what you are reciting aloud really *is* the alphabet?

Of course that is the same question as "How do you know that what you call 'red' is really the same as what another calls 'red'?" And in its metaphysical use the one question makes no more sense than the other.

In these examples, I would like to say, you see how the words are really used.

90 One might think: What a remarkable process willing must be,

if I can now will the very thing I won't be doing until five minutes hence!

Page 137

How can I expect the event, when it isn't yet there at all?

Page 137

"Socrates: so if someone has an idea of what is not, he has an idea of nothing?--Theaetetus: It seems so. Socrates: But surely if he has an idea of nothing, then he hasn't any idea at all?--Theaetetus: That seems plain."†1

Page 137

If we put the word "kill", say, in place of "have an idea of" in this argument, then there is a rule for the use of this word: it makes no sense to say "I am killing something that does not exist". I can imagine a stag that is not there, in this meadow, but not kill one that is not there. And "to imagine a stag in this meadow" means to imagine *that* a stag is there. But to kill a stag does not mean to kill *that*... But if someone says "in order for me to be able to imagine a stag it must after all exist in some sense", the answer is: no, it does not have to *exist* in any sense. And if it should be replied: "But the colour brown at any rate must exist, for me to be able to have an idea of it"--then we can say 'the colour brown exists' means nothing at all; except that it exists here or there as the colouring of an object, and that is not necessary in order for me to be able to imagine a brown stag.

Page 137

We say that the expression of expectation 'describes' the expected fact and think of an object or complex which makes its appearance as fulfilment of the expectation.--But it is not the expected thing that is the fulfilment, but rather: its coming about.

Page 137

The mistake is deeply rooted in our language: we say "I expect him" and "I expect his arrival".

Page 137

It is difficult for us to shake off this comparison: a man makes his appearance--an event makes its appearance. As if an event even now stood in readiness before the door of reality and were then to make its appearance in reality--like coming into a room.

Page Break 138

Page 138

91 I can look for him when he is not there, but not hang him when he is not there.

Page 138

One might want to say: "But he must be somewhere there if I am looking for him."--Then he must be somewhere there too if I don't find him and even if he doesn't exist at all.

Page 138

A search for a particular thing (e.g. my stick) is a particular kind of search, and differs from a search for something else because of what one does (says, thinks) while searching, not because of what one finds.

Page 138

Suppose while I am searching I carry with me a picture or an image--very well. If I say that the picture is a picture of what I am looking for, that merely tells the place of the picture in the process of searching. And if I find it and say "There it is! *That's* what I was looking for" those words aren't a kind of definition of the name of the object of the search (e.g. of the words "my stick"), a definition that couldn't have been given until the object had been found.

Page 138

"You were looking for *him*? You can't even have known if he was there!" (Contrast looking for the trisection of the angle.)

Page 138

One may say of the bearer of a name that he does not exist; and of course that is not an activity, although one may compare it with one and say: he must be there all the same, if he does not exist. (And this has certainly already been written some time by a philosopher.)

Page 138

The idea that it takes finding to show what we were looking for, and fulfilment of a wish to show what we wanted, means one is judging the process like the symptoms of expectation or search in someone else. I see him uneasily pacing up and down his room; then someone comes in at the door and he relaxes and gives signs of satisfaction. And I say "obviously he was expecting this person."

Page 138

The symptoms of expectation are not the expression of expectation.

One may have the feeling that in the sentence "I expect he is coming" one is using the words "he is coming" in a different sense from the one they have in the assertion "he is coming". But if it were so, how could I say that my expectation had been fulfilled? And the words "he is coming" mean the same in the expression of expectation as in the description of its fulfilment, because if I wanted to explain the words "he" and "is coming", say by means of ostensive definitions, the same definitions of these words would go for both sentences.

But it might now be asked: what's it like for him to come?--The door opens, someone walks in, and so on.--What's it like for me to expect him to come?--I walk up and down the room, look at the clock now and then, and so on. But the one set of events has not the smallest similarity to the other! So how can one use the same words in describing them? What has become now of the hollow space and the corresponding solid?

But perhaps I say as I walk up and down: "I expect he'll come in." Now there is a similarity somewhere. But of what kind?!

But of course I might walk up and down in my room and look at the clock and so on without expecting him to come. I wouldn't describe doing that by saying "I expect he is coming". So what made it e.g. the expectation precisely of *him*?

I may indeed say: to walk restlessly up and down in my room, to look at the door, to listen for a noise is: to expect N.--That is simply a definition of the expression "to expect N". Of course it isn't a definition of the word "expect", because it doesn't explain what e.g. "to expect M" means. Well, we can take care of that; we say something like: to expect X means to act as described and to utter the name "X" while doing so. On this definition the person expected is the person whose name is uttered. Or I may give as a definition: to expect a person X is to do what I described in the second example, and to make a drawing of a person. In that case, the person expected is the bearer of the name X, the person who corresponds to the drawing.--That of course wouldn't explain

what "to expect N to go" means, and I would have to give either an independent definition of that, or a general definition including going and coming. And even that wouldn't explain say what "to expect a storm" means; etc. etc.

What characterizes all these cases is, that the definition can be used to read off the object of the expectation from the expectant behaviour. It isn't a later experience that decides *what* we are expecting.

And I may say: it is in language that expectation and its fulfilment make contact.

So *in this case* the behaviour of the expectant person is behaviour which can be translated in accordance with given rules into the proposition "He is expecting it to happen that p". And so the simplest typical example to illustrate this use of the word "expect" is that the expectation of its happening that p should consist in the expectant person *saying* "I expect it to happen that p". Hence in so many cases it clarifies the grammatical situation to say: let us put the expression of expectation in place of the expectation, the expression of the thought in place of the thought.

93 One can conceive expectation as expectant, preparatory behaviour. Expectation is like a player in a ball game holding his hands in the right position to catch the ball. The expectation of the player might consist in his holding out his hands in a particular way and looking at the ball.

Some will perhaps want to say: "An expectation is a thought". Obviously, that corresponds to one use of the word "expect". And we need to remember that the process of thinking may be *very various*.†1

And if expectation is the thought "I am expecting it to happen that p" it is senseless to say that I won't perhaps know until later what I expected.

Something analogous might be said of wishing, fear and hope. (Plato called hope "a speech"†1).

Page 141

But it is different if *hunger* is called "a wish", say the body's wish for food to satisfy it. For it is a hypothesis that just that will satisfy the wish; there's room for conjecture and doubt on the topic.

Page 141

Similarly if what I call "expectation" is a feeling, say a feeling of disquiet or dissatisfaction. But of course these feelings are not thoughts in an amorphous form.

Page 141

The idea of thought as an unexplained process in the human mind makes it possible to imagine it turned into a persistent amorphous condition.

Page 141

If I say "I have been expecting him all day", "expect" here doesn't mean a persistent condition including as ingredients the person expected and his arrival, in the way that a dough may contain flour, sugar and eggs mixed into a paste. What constitutes expectation is a series of actions, thoughts and feelings.

Page 141

94 When I expect someone,--what happens? I perhaps look at my calendar and see his name against today's date and the note "5 p.m." I say to someone else "I can't come to see you today, because I'm expecting N". I make preparations to receive a guest. I wonder "Does N smoke?", I remember having seen him smoke and put out cigarettes. Towards 5 p.m. I say to myself "Now he'll come soon", and as I do so I imagine a man looking like N; then I imagine him coming into the room and my greeting him and calling him by his name. This and many other more or less *similar* trains of events are called "expecting N to come".

Page Break 142

Page 142

But perhaps I'm also prepared to say "I have been expecting N" in a case where the only thing that connects him with my expectant activity is for instance that on a particular day I prepare a meal for myself and one other person, and that N. has announced his intention of taking that meal with me.

Page 142

What does the process or state of wanting an apple consist in? Perhaps I experience hunger or thirst or both, and meanwhile imagine an apple, or remember that I enjoyed one yesterday; perhaps I say "I would like to eat an apple"; perhaps I go and look in a cupboard where apples are normally kept. Perhaps all these states and activities are combined among themselves and with others.

Page 142

95 The same sort of thing must be said of intention. If a mechanism is *meant* to act as a brake, but for some reason does not slow down the motion of the machine, then the purpose of the mechanism cannot be found out *immediately* from it and from its effect. If you were to say "that is a brake, but it doesn't work" you would be talking about intention. But now suppose that whenever the mechanism didn't work as a brake a particular person became angry. Wouldn't the intention of the mechanism now be expressed in its effect? No, for now it could be said that the lever sometimes triggers the brake and sometimes triggers the anger. For how does it come out that the man is angry *because* the lever doesn't operate the brake? "Being annoyed that the apparatus does not function" is itself something like "wishing that it did function in that way".--Here we have the old problem, which we would like to express in the following way: "the thought that p is the case doesn't presuppose that it is the case; yet on the other hand there must be something in the fact that is a presupposition even of having the thought (I can't think that something is red, if the colour red does not exist)". It is the problem of the harmony between world and thought.--To this it may be replied that thoughts are in the same

Page Break 143

space as the things that admit of doubt; they are laid against them in the same way as a ruler is laid against what is to be measured.

Page 143

What I really want to say is this: the wish that he should come is the wish that really *he* should really *come*. If a further explanation of this assurance is wanted, I would go on to say "and by 'he' I mean that man there, and by 'come' I mean doing this..." But these are just grammatical explanations, explanations which *create* language.

Page 143

It is *in language* that it's all done.

Page 143

"I couldn't think that something is red if red didn't exist." What that proposition really means is the image of something red, or the existence of a red sample *as part of our language*. But of course one can't say that our language *has to* contain such a sample; if it didn't contain it, it would just be another, a different language. But one can say, and emphasize, that it does contain it.

Page 143

96 It's beginning to look somehow as if intention could never be recognized as *intention* from outside; as if one must be doing the meaning of it oneself in order to understand it as meaning. That would amount to considering it not as a phenomenon or fact but as something intentional which has a direction given to it. What this direction is, we do not know; it is something which is absent from the phenomenon as such.

Page 143

Here, of course, our earlier problem returns, because the point is that one has to read off from a thought that it is the thought that such and such is the case. If one can't read it off (as one can't read off the cause of a stomach-ache) then it is of no logical interest.

Page 143

My idea seems nonsensical if it is expressed like *this*. It's supposed to be possible to see what someone is thinking of by opening up his head. But how is that possible? The objects he's thinking about are certainly not in his head--any more than in his thoughts!

Page Break 144

Page 144

If we consider them 'from outside' we have to understand thoughts as thoughts, intentions as intentions and so on, *without* getting any information about something's meaning. For it is with the phenomenon of thinking that meaning belongs.

Page 144

If a thought is observed there can be no further question of an understanding; for if the thought is seen it must be recognized as a thought with a certain content; it doesn't need to be interpreted!--That really is how it is; when we are thinking, there isn't any interpretation going on.

Page 144

97 If I said "but that would mean considering intention as something other than a phenomenon" that would make intention reminiscent of the will as conceived by Schopenhauer. Every phenomenon seems dead in comparison with the living thought.

Page 144

"Intention seen from outside" is connected with the question whether a machine could think. "Whatever phenomenon we saw, it couldn't ever be intention; for that has to contain the very thing that is intended, and any phenomenon would be something complete in itself and unconcerned with anything outside itself, something merely dead if considered by itself."

Page 144

This is like when we say: "The will can't be a phenomenon, for whatever phenomenon you take is something that *simply happens*, something we undergo, not something we *do*. The will isn't *something* I see happen, it's more like my being involved in my actions, my *being* my actions." Look at your arm and move it and you will experience this very vividly: "You aren't observing it moving itself, you aren't having an experience--not just an experience, anyway--you're *doing* something." You may tell yourself that you could also imagine exactly the same thing happening to your hand, but merely observed and not willed by you. But shut your eyes, and move your arm so that you have, among other things, a certain experience: now ask yourself whether you still can imagine that you were having the same experience but without willing it.

Page Break 145

Page 145

If someone wants to express the distinction between voluntary and involuntary movements by saying that voluntary movements of the arm, for example, are differentiated from involuntary ones by a feeling of innervation, you feel an urge to say "But I don't *undergo* this experience, I *do* it --" But *can* one speak of a distinction between undergoing and doing in the case of an experience of innervation? I would like to say: "If I will, then there isn't anything that happens to me, neither the movement nor a feeling; I am the agent." Very well; but there's no doubt that you *also* have experiences when you voluntarily move your arm; because you *see* (and feel) it moving whether or not you take up the attitude of an *observer*. So just for once try to distinguish between *all the experiences* of acting plus the doing (which is not an experience) and *all* those experiences without the element of doing. Think over whether you still need this element, or whether it is beginning to appear redundant.--Of course you can say

correctly that when you do something, there isn't anything happening to you, because the phenomena of doing *are* different from the phenomena of observing something like a reflex movement. But this doesn't become clear until one considers the very different sorts of things that people call voluntary activities and that people call unintentional or involuntary processes in our life. (More about this in another place.)

Page 145

98 By "intention" I mean here what uses a sign in a thought. The intention seems to interpret, to give the final interpretation; which is not a further sign or picture, but something else, the thing that cannot be further interpreted. But what we have reached is a psychological, not a logical terminus.

Page 145

Think of a sign language, an 'abstract' one, I mean one that is strange to us, in which we do not feel at home, in which, as we should say, we do not *think* (we used a similar example once before), and let us imagine this language interpreted by a translation into--as we should like to say--an unambiguous picture-language, a language consisting of pictures painted in perspective. It is quite

Page Break 146

clear that it is much easier to imagine different *interpretations* of the written language than of a picture painted in the usual way depicting say a room with normal furniture. Here we shall also be inclined to think that there is no further possibility of interpretation.

Page 146

Here we might also say we didn't enter into the sign-language, but did enter into the painted picture.

Page 146

(This is connected with the fact that what we call a 'picture by similarity' is not a picture in accordance with some established method of projection. In this case the "likeness" between two objects means something like the possibility of mistaking one for the other.)

Page 146

"Only the intended picture reaches up to reality like a yardstick. Looked at from outside, there it is, lifeless and isolated."--It is as if at first we looked at a picture so as to enter into it and the objects in it surrounded us like real ones; and then we stepped back, and were now outside it; we saw the frame, and the picture was a painted surface. In this way, when we intend, we are surrounded by our intention's pictures and we are inside them. But when we step outside intention, they are mere patches on a canvas, without life and of no interest to us. When we intend, we exist among the pictures (shadows) of intention, as well as with real things. Let us imagine we are sitting in a darkened cinema and entering into the happenings in the film. Now the lights are turned on, though the film continues on the screen. But suddenly we see it "from outside" as movements of light and dark patches on a screen.

Page 146

(In dreams it sometimes happens that we first read a story and then are ourselves participants in it. And after waking up after a dream it is sometimes as if we had stepped back out of the dream and now see it before us as an alien picture.) And it also means something to speak of "living in the pages of a book". That is

Page Break 147

connected with the fact that our body is not at all essential for the occurrence of our experience. (Cf. eye and visual field.)

Page 147

(Compare also the remark: if we understand a sentence, it has a certain depth for us.)

Page 147

99 What happens is not that this symbol cannot be further interpreted, but: I do no interpreting. I do not interpret because I feel natural in the present picture. When I interpret, I step from one level of my thought to another.

Page 147

If I see the thought symbol "from outside", I become conscious that it *could* be interpreted thus or thus; if it is a step in the course of my thoughts, then it is a stopping-place that is natural to me, and its further interpretability does not occupy (or trouble) me. As I have a railway time-table and use it without being concerned with the fact that a table can be interpreted in various ways.

Page 147

When I said that my image wouldn't be a portrait unless it bore the name of its subject, I didn't mean that I have to imagine it and his name at the same time. Suppose I say something like: "What I see in my mind isn't just a picture which is like N (and perhaps like others too). No, I know that it is him, that he is the person it portrays." I might then ask: *when* do I know that and what does knowing it amount to? There's no need for anything to take place during the imagining that could be called "knowing" in this way. Something of that sort may happen after the

imagining; I may go on from the picture to the name, or perhaps say that I imagined N, even though at the time of the imagining there wasn't anything, except a kind of similarity, to characterize the image as N's. Or again there might be something preceding the image that made the connection with N. And so the interpretation isn't something that accompanies the image; what gives the image its interpretation is the *path* on which it lies.

Page 147

That all becomes clearer if one imagines images replaced by

Page Break 148

drawings, if one imagines people who go in for drawing instead of imagining.

Page 148

100 If I try to describe the process of intention, I feel first and foremost that it can do what it is supposed to only by containing an extremely faithful picture of what it intends. But further, that that too does not go far enough, because a picture, whatever it may be, can be variously interpreted; hence this picture too in its turn stands isolated. When one has the picture in view by itself it is suddenly dead, and it is as if something had been taken away from it, which had given it life before. It is not a thought, not an intention; whatever accompaniments we imagine for it, articulate or inarticulate processes, or any feeling whatsoever, it remains isolated, it does not point outside itself to a reality beyond.

Page 148

Now one says: "Of course it is not the picture that intends, but we who use it to intend." But if this intending, this meaning, is something that is done with the picture, then I cannot see why that has to involve a human being. The process of digestion can also be studied as a chemical process, independently of whether it takes place in a living being. We want to say "Meaning is surely essentially a mental process, a process of consciousness and life, not of dead matter." But what will give such a thing the specific character of what goes on?--so long as we speak of it as a process. And now it seems to us as if intending could not be any process at all, of any kind whatever.--For what we are dissatisfied with here is the grammar of *process*, not the specific kind of process.--It could be said: we should call any process 'dead' in this sense.

Page 148

Let's say the wish for this table to be a little higher is the act of my holding my hand above the table at the height I wish it to be. Now comes the objection: "The hand above the table can't be the wish: it doesn't express that the table is to be higher; it is

Page Break 149

where it is and the table is where it is. And *whatever other* gesture I made it wouldn't make any difference."

Page 149

(It might almost be said: "Meaning *moves*, whereas a process stands still.")

Page 149

101 However, if I imagine the expression of a wish as the act of wishing, the problem appears solved, because the system of language seems to provide me with a medium in which the proposition is no longer dead.

Page 149

If we imagine the expression of a wish as the wish, it is rather as if we were led by a train of thought to imagine something like a network of lines spread over the earth, and living beings who moved only along the lines.

Page 149

But now someone will say: even if the *expression* of the wish is the wish, still the whole language isn't present during this expression, yet surely the wish is!

Page 149

So how does language help? Well, it just isn't necessary that anything should be *present* except the expression.

Page 149

102 You might as it were locate (look up) all of the connections in the grammar of the language. There you can see the whole network to which the sentence belongs.

Page 149

Suppose we're asked "When we're thinking, meaning and so on why don't we come upon the bare picture?" We must tell ourselves that when we're thinking we don't wonder whether the picture is the thought or the meaning, we simply *use* pictures, sentences and so on and discard them one after the other.

Page 149

But of course if you call the picture the wish (e.g. that this table were higher) then what you're doing is comparing the picture with an expression of our language, and certainly it doesn't correspond to such an expression

unless it's part of a system translatable into our language.

Page 149

One says: how can this way of holding the hand, this picture

Page Break 150

be the wish that such and such were the case? It is nothing more than a hand over a table, and there it is, alone and without a *sense*. Like a single bit of scenery from the production of a play which has been left by itself. It had life only in the play.

Page 150

In the gesture we don't see the real shadow of the fulfilment, the unambiguous shadow that admits of no further interpretation.

Page 150

We ask: "does the hand above a table wish?" Does anything, spiritual or material, that we might add, wish? Is there any such situation or process that really contains what is wished?--And what is our paradigm of such containing? Isn't it our language? Where are we to find what makes the wish *this* wish, even though it's only a wish? Nowhere but in the expressed wish.

Page 150

"After all, the wish must show *what* is wished, it must prefigure in the realm of wishes that which is wished." But what actual process do you have in mind here as the prefiguring? (What is the mirror in which you think you saw what was wished?)

Page 150

"The gesture *tries* to prefigure" one wants to say "but it can't".

Page 150

103 Can one say that *while I'm wishing* my wish seems to prefigure the fulfilment? While I'm wishing it doesn't *seem* to do anything; I notice nothing odd about it. It's only considering the linguistic manifestation of the wish that produces this appearance.

Page 150

We are considering an event that we might call an instance of the wish that this table were higher. But this event *doesn't even seem* to contain the fulfilment. Now someone says: "But this event does have to be a shadow of the very state of affairs that is wished, and

Page Break 151

these actions aren't that." But why do you say that's what a wish has to be? "Well, because it's the wish that just that were the case". Precisely: that's the only answer you can give to the question. So after all that event is the shadow, insofar as it corresponds within a system to the expression of the wish in the word-language. (It is in language that wish and fulfilment meet.) Remember that the expression of a wish can be the wish, and that the expression doesn't derive its sense from the presence of some extraordinary spirit.

Page 151

Think also of a case very similar to the present one: "This table isn't 80 cm high". Must the fact that it is 90 cm, and so *not* 80 cm, high contain the shadow of the fact of its being 80 cm high? What gives this impression? When I see a table which is 90 cm high does it give a shadowy impression of having a height it doesn't have?

Page 151

This is rather as if we misunderstood the assertion " $\vdash \sim p$ " in such a way as to think that it contained the assertion " $\vdash p$ ", rather as " $\vdash p.q$ " contains in its sense " $\vdash p$ ".

Page 151

Someone describes to me what went on when he, as he says, had the wish that the table were 10 cm higher. He says that he held his hand 10 cm above the table. I reply "But how do you know that you weren't just wishing that the table were higher, since in that case too you would have held your hand at some height above the table." He says "After all, I must know what I wished" I reply "Very well, but I want to know *by what token* you remember when you remember your wish. What *happened* when you wished, and what makes you say you wished just that?" He says "I know that I *intentionally* held my hand just 10 cm above." I say "But what constituted just *that* intention?"--I might also ask "Is it certain that when you were wishing you were using the scale 1:1? How do you know that?"

Page 151

If he had described the process of wishing by saying "I said 'I would like to have the table 10 cm higher'", then the question

how he could know what he wished wouldn't have arisen. (Unless someone had gone on to ask: "And did you *mean* those words in the way they are usually meant?")

What it always comes to in the end is that without any further *meaning* he *calls* what happened the wish that that should happen. [Manifestation, not description.]

"How do I know it's *him* I'm remembering, if the remembering is a picture?" To what extent *do* I know it? ("When two men look perfectly alike, how can I remember one of them in particular?")

104 We say "A proposition isn't just a series of sounds, it is something more". We think of the way a Chinese sentence is a mere series of sounds for us, which just means that we don't understand it, and we say this is because we don't have any thoughts in connection with the Chinese sentence (e.g. the Chinese word for "red" doesn't call up any image in us). "So what distinguishes a significant sentence from mere sounds is the thoughts it evokes." The sentence is like a key-bit whose indentations are constructed to move levers in the soul in a particular way. The sentence, as it were, plays a melody (the thought) on the instrument of the soul. But why should I now hypothesize, in addition to the orderly series of words, another series of mental elements running parallel? That simply duplicates language with something else of the same kind.

Suppose the sentence is: "This afternoon N went into the Senate House." The sentence isn't a mere noise for me, it evokes an image of a man in the vicinity of the Senate House, or something similar. But the sentence and the image aren't just a noise plus a faint image; calling up the image, and having certain other consequences, is something as it were internal to the sentence; *that* is what its sense is. The image seems only a faint copy of the sense, or shall we say, only a single view of the sense.--But what do I mean by this? Don't I just see the sentence as part of a system of consequences?

Let us suppose that proposition evoked in me a very clear picture of N on the way to the Senate House and that in the picture there could also be seen the setting sun ("evening") and a calendar with today's date. Suppose that instead of letting the sentence call up this picture, I actually painted it and showed it to someone else as a means of communication in place of the sentence. He might say of this too that it expressed a thought but needed to be understood; what he would think of as an act of understanding would probably be a translation into word languages.

"I arrive in Vienna on the 24th of December." They aren't mere words! Of course not: when I read them various things happen inside me in addition to the perception of the words: maybe I feel joy, I have images, and so on.--But I don't just mean that various more or less inessential concomitant phenomena occur in conjunction with the sentence; I mean that the sentence has a definite sense and I perceive it. But then what is this definite sense? Well, that this particular person, whom I know, arrives at such and such a place etc. Precisely: when you are giving the sense, you are moving around in the grammatical background of the sentence. You're looking at the various transformations and consequences of the sentence as laid out in advance; and so they are, in so far as they are embodied in a grammar. (You are simply looking at the sentence as a move in a given game.)

I said that it is the *system* of language that makes the sentence a thought and makes it a thought *for us*.

That doesn't mean that it is while we are using a sentence that the system of language makes it into a thought for us, because the system isn't present then and there isn't any need for anything to make the sentence alive for us, since the question of being alive doesn't arise. But if we ask: "why doesn't a sentence strike us as isolated and dead when we are reflecting on its essence, its sense, the thought etc." it can be said that we are continuing to move in the system of language.

To match the words "I grasp the sense" or "I am thinking the thought of this sentence" you hypothesize a process which unlike the bare propositional sign contains these consequences.

105 "This queer thing, thought": but it does not strike us as queer while we are thinking *it*. It strikes us as queer

when we tell ourselves that it connects objects in the mind, because it is the very thought that *this person is doing that*; or that it isn't a sign or a picture, because I would still have to know how they were meant in their turn; or that thought isn't something dead, because *for me* what I think *really* happens.

Page 154

What is the source of this odd way of looking at things?

Page 154

What makes us think that a thought, or a proposition we think, contains the reality? It's that we're all ready to pass from it to the reality, and we feel this transition as something already potentially contained in it (when, that is, we reflect on it), because we say "that word *meant him*". We feel this transition as something just as legitimate as a permitted move in a game.

Page 154

Thought does not strike us as mysterious while we are thinking, but only when we say, as it were retrospectively: "How was that possible?" How was it possible for thought to deal with the very person *himself*? But here I am merely being astonished by my own linguistic expression and momentarily misunderstanding it.

Page 154

Thought strikes us as mysterious. But not while we think. And we don't mean that it's psychologically remarkable. It isn't only that we see it as an extraordinary way of producing pictures and signs, we actually feel as if by means of it we had caught reality in our net.

Page 154

It isn't while we're *looking at* it that it seems a strange process; but when we let ourselves be guided by language, when we look at what we say about it.

Page 154

We mistakenly locate this mystery in the nature of the process.

Page Break 155

(We interpret the enigma created by our misunderstanding as the enigma of an incomprehensible process.)

Page 155

106 "Thought is a remarkable process, because when I think of what will happen tomorrow, I am mentally already in the future." If one doesn't understand the grammar of the proposition "I am mentally in the future" one will believe that here the future is in some strange way caught in the sense of a sentence, in the meaning of words. Similarly people think that the endless series of cardinal numbers is somehow before our mind's eye, whenever we can use that expression significantly.

Page 155

"For me this portrait is *him*"? What does that mean? I have the same attitude to the portrait, as to the man himself. For I do of course distinguish between him and his picture.

Page 155

A thought experiment comes to much the same as an experiment which is sketched or painted or described instead of being carried out. And so the result of a thought experiment is the fictitious result of a fictitious experiment.

Page 155

"The sense of this proposition was present to me." What was it that happened?

Page 155

"Only someone who is *convinced* can say that".--How does the conviction help him when he says it?--Is it somewhere at hand by the side of the spoken expression? (Or is it masked by it, as a soft sound by a loud one, so that it can, as it were, no longer be heard when one expresses it out loud?) What if someone were to say "In order to be able to sing a tune from memory one has to hear it in one's mind and sing from that"?

Page 155

Try the following experiment: Say a sentence, perhaps "The weather is very fine today"; right, and now think the thought of the sentence, but unadulterated, without the sentence.

Page Break 156

Page 156

107 "It looks as if intention could never be recognized as intention "from outside", as if one must be doing the meaning of it oneself in order to understand it as meaning."†1

Page 156

Can one recognize stomach-ache as such "from outside"? What are stomach-aches "from outside"? Here there is no outside or inside! Of course, in so far as meaning is a specific experience, one wouldn't call any other

experience "meaning". Only it isn't any remarkable feature of the sensation which explains the directionality of meaning. And if we say "from outside intention cannot be recognised as intention etc." we don't want to say that meaning is a special experience, but that it isn't anything which happens, or happens to us, but something that we do, otherwise it would be just dead. (The subject--we want to say--does not here drop out of the experience but is so much involved in it that the experience cannot be described.)

Page 156

It is almost as if one said: we can't see ourselves going hither and thither, because it is we who are doing the going (and so we can't stand still and watch). But here, as so very often, we are suffering from an inadequate form of expression, which we are using at the very time we want to shake it off. We clothe the protest against our form of expression in an apparently factual proposition expressed in that very form. For if we say "we see ourselves going thither" we mean simply that we see what someone sees when he is going himself and not what he sees if someone else is going. And one does indeed have a particular visual experience if one is doing the going oneself.

Page 156

That is to say, what we are speaking of is a case in which contrary to experience the subject is linked like an element in a chemical compound. But where do we get this idea from? The concept of living activity in contrast with dead phenomena.

Page Break 157

Page 157

Imagine someone now saying: "going somewhere oneself isn't an experience".

Page 157

We want to say: "When we mean something, there isn't a dead picture (of any kind); it's as if we went up to someone. We go up to what we mean."

Page 157

But here we're constructing a false contrast between experience and something else, as if experience consisted of sitting still and letting pictures pass in front of one.

Page 157

"When one means, it is oneself doing the meaning"; similarly, it is oneself that does the moving. One rushes forward oneself, and one can't simultaneously observe the rushing. Of course not.

Page 157

Yes, meaning something is like going up to someone.

Page 157

108 Fulfilment of expectation doesn't consist in this: a third thing happens which can be described otherwise than as "the fulfilment of this expectation", i.e. as a feeling of satisfaction or joy or whatever it may be. The expectation that something will be the case is the same as the expectation of the fulfilment of that expectation.

Page 157

Could the justification of an action as fulfilment of an order run like this: "You said 'bring me a yellow flower', upon which this one gave me a feeling of satisfaction; that is why I have brought it"? Wouldn't one have to reply: "But I didn't set you to bring me the flower which should give you that sort of feeling after what I said!"

Page 157

(I go to look for the yellow flower. Suppose that while I am looking a picture comes before my mind,--even so, do I need it when I see the yellow flower--or another flower? If I say: "as soon as I see a yellow flower, something as it were clicks into place in my memory"--rather like a lever into a cog in the striking mechanism of a clock--can I foresee, or expect, this clicking into place any better than the yellow flower? Even if in a particular case

Page Break 158

it really is true that what I'm expecting isn't what I am looking for, but some other (indirect) criterion, that certainly isn't an explanation of expectation.)

Page 158

But isn't the occurrence of what is expected always accompanied by a phenomenon of agreement (or satisfaction?). Is this phenomenon something different from the occurrence of what is expected? If so, then I don't know whether fulfilment is always accompanied by such a phenomenon.

Page 158

If I say: the person whose expectation is fulfilled doesn't have to shout out "yes, that is it" or the like--I may be told: "Certainly, but he must *know* that the expectation is fulfilled." Yes, if the knowledge is part of its *being* fulfilled. "Yes, but when someone has his expectation fulfilled, there's always a relaxation of tension!"--How do you

know that?

Page Break 159

VIII

Page 159

109 A description of language must achieve the same result as language itself. "For in that case I really can learn from the proposition, from the description of reality, how things are in reality."--Of course it's only *this* that is called description, or "learning how things are". And that is all that is ever said when we say that we learn from the description how things are in reality.

Page 159

"From the order you get the knowledge of what you have to do. And yet the order only gives you itself, and its effect is neither here nor there." But here we are simply misled by the form of expression of our language, when it says "the knowledge of *what* you have to do" or "the knowledge of the action". For then it looks as if this something, the action, is a thing which is to come into existence when the order is carried out, and as if the order made us acquainted with this very thing by showing it us in such a way that it already in a certain sense brought it into existence. (How can a command--an expectation--show us a man before he has come into the room?)

Page 159

Suppose someone says that one can infer from an order the action that obeys it, and from a proposition the fact which verifies it. What on earth can one infer from a proposition apart from *itself*? How can one pull the action out of the order before it takes place? Unless what is meant is a different form of description of the action, such as say making a drawing, in accordance with the order, of what I'm to do. But even this further description isn't there until I have drawn it; it doesn't have a shadowy existence in the order itself.

Page 159

Being able to do something seems like a shadow of the actual doing, just as the sense of a sentence seems like the shadow of a fact, and the understanding of an order the shadow of its execution.

Page Break 160

In the order the fact as it were "casts its shadow before it"! But this shadow, whatever it may be, is not the event.

Page 160

The shadowy anticipation of the fact consists in our being able already to think that *that very thing* will happen, which *hasn't yet* happened. Or, as it is misleadingly put, in our being now able to think of (or about) *what hasn't yet* happened.

Page 160

110 Thinking plus its application proceeds step by step like a calculus.--However many intermediate steps I insert between the thought and its application, each intermediate step always follows the previous one without any intermediate link, and so too the application follows the last intermediate step. It is the same as when we want to insert intermediate links between decision and action.

Page 160

The ambiguity of our ways of expressing ourselves: If an order were given us in code with the key for translating in into English, we might call the procedure of constructing the English form of the order "derivation of what we have to do from the code" or "derivation of what executing the order is". If on the other hand we act according to the order, obey it, here too in certain cases one may speak of a derivation of the execution.

Page 160

We can't cross the bridge to the execution until we are there.

Page 160

111 It is as a calculus that thinking has an interest for us; not as an activity of the human imagination.

Page 160

It is the *calculus* of thought that connects with extra-mental reality.

Page 160

From expectation to fulfilment is a step in a calculation. Indeed, the relation between the calculation

$$\begin{array}{r} 25 \times 25 \\ \hline 50 \\ 125 \\ \hline \end{array}$$

and its result 625 is exactly the same as that between expectation

and its fulfilment. Expectation is a picture of its fulfilment to exactly the same degree as this calculation is a picture of its result, and the fulfilment is determined by the expectation to exactly the same degree as the result is determined by the calculation.

112 When I think in language, there aren't meanings going through my mind in addition to the verbal expressions; the language is itself the vehicle of thought.

In what sense does an order anticipate its execution? By ordering *just that* which later on is carried out? But one would have to say "which later on is carried out, or again is not carried out". And that is to say nothing.

"But even if my wish does not determine what is going to be the case, still it does so to speak determine the theme of a fact, whether the fact fulfils the wish or not." We are--as it were--surprised, not at anyone's knowing the future, but at his being able to prophesy at all (right or wrong).

As if the mere prophecy, no matter whether true or false, foreshadowed the future; whereas it knows nothing of the future and cannot know less than nothing.

Suppose you now ask: then are facts defined one way or another by an expectation--that is, is it defined for whatever event may occur whether it fulfils the expectation or not? The answer has to be: Yes, unless the expression of the expectation is indefinite, e.g. by containing a disjunction of different possibilities.

"The proposition determines in advance what will make it true." Certainly, the proposition "p" determines that p must be the case in order to make it true; and that means:

(the proposition p) = (the proposition that the fact p makes true). And the statement that the wish for it to be the case that p is satisfied by the event p, merely enunciates a rule for signs:

(the wish for it to be the case that p) = (the wish that is satisfied by the event p).

Like everything metaphysical the harmony between thought and reality is to be found in the grammar of the language.

IX

113 Here instead of harmony or agreement of thought and reality one might say: the pictorial character of thought. But is this pictorial character an agreement? In the *Tractatus* I had said something like: it is an agreement of form. But that is misleading.

Anything can be a picture of anything, if we extend the concept of picture sufficiently. If not, we have to explain what we call a picture of something, and what we want to call the agreement of the pictorial character, the agreement of the forms.

For what I said really boils down to this: that every projection must have something in common with what is projected no matter what is the method of projection. But that only means that I am here extending the concept of 'having in common' and am making it equivalent to the general concept of projection. So I am only drawing attention to a possibility of generalization (which of course can be very important).

The agreement of thought and reality consists in this: if I say falsely that something is *red*, then, for all that, it isn't *red*. And when I want to explain the word "red" to someone, in the sentence "That is not red", I do it by pointing to something red.

In what sense can I say that a proposition is a picture? When I think about it, I want to say: it must be a picture if it is to show me what I am to do, if I am to be able to act in accordance with it. But in that case all you want to say is that you act in accordance with a proposition in the same sense as you act in accordance with a picture.

To say that a proposition is a picture gives prominence to certain features of the grammar of the word "proposition".

Thinking is quite comparable to the drawing of pictures.

But one can also say that what looks like an analogue of a proposition is actually a particular case of our general concept. When I compared the proposition with a ruler, strictly speaking what I did was to take the use of a ruler in making a statement of length as an example for all propositions.

114 The sense of a proposition and the sense of a picture. If we compare a proposition with a picture, we must think whether we are comparing it to a portrait (a historical representation) or to a genre-picture. And both comparisons have point.

Sentences in fiction correspond to genre-pictures.

"When I look at a genre-picture, it 'tells' me something even though I don't believe (imagine) for a moment that the people I see in it really exist, or that there have really been people in that situation."

Think of the quite different grammar of the expressions:

"This picture shows people in a village inn."

"This picture shows the coronation of Napoleon."

(Socrates: "And if you have an idea must it not be an idea of *something*?"--Theaetetus:

"Necessarily."--Socrates: "And if you have an idea of something, mustn't it be of something real?"--Theaetetus: "It seems so").†1

Does the picture tell me, for instance, "two people are sitting in an inn drinking wine?" Only if this proposition somehow enters into the process of understanding *outside the picture*, say if I say which I look at the picture "here two people are sitting etc." If the picture tells me something in this sense, it tells me *words*. But how far does it declare itself in these words? After all, if reality is declaring itself via language, it is taking a long way round.

So for the picture to tell me something it isn't essential that words should occur to me while I look at it; because the picture was supposed to be the more direct language.

Here it is important to realise that instead of a picture one might have considered a slice of material reality. For although our

attitude to a painted table derives historically from our attitude to real tables, the latter is not a part of the former.

115 So what the picture tells me is itself.

Its telling me something will consist in my recognizing in it objects in some sort of characteristic arrangement. (If I say: "I see a table in this picture" then what I say characterizes the picture--as I said--in a manner which has nothing to do with the existence of a 'real' table. "The picture shows me a cube" can e.g. mean: It contains

the form  .)

Asked "Did you recognize your desk when you entered your room this morning?"--I should no doubt say "Certainly!" and yet it would be misleading to call what took place "a recognition". Certainly the desk was not strange to me; I was not surprised to see it, as I should have been if another one had been standing there, or some

unfamiliar kind of object.

Page 165

"Something is familiar if I know what it is."

Page 165

"What does it mean: 'this object is familiar to me?'--"Well, I know that it's a table." But that can mean any number of things, such as "I know how it's used", "I know it looks like a table when it's opened out", "I know that it's what people call 'a table'."

Page 165

What kind of thing is "familiarity"? What constitutes a view's being familiar to me? (The question itself is peculiar; it does not sound like a grammatical question.)

Page 165

I would like to say: "I see what I see". And the familiarity can only consist in my being at home in what I see.

Page 165

116 "I see what I see": I say that because I don't want to give a name to what I see. I don't want to say "I see a flower" because that

Page Break 166

presupposes a linguistic convention, and I want a form of expression that makes no reference to the history of the impression.

Page 166

The familiarity consists in my recognizing that what I see is a flower. I may say: the utterance of the words "that is a flower" is a recognition reaction; but the criterion for recognition isn't that I name the object correctly, but that when I look at it I utter a series of sounds and have a certain experience. For that the sounds are the correct English word, or that they are a word at all in any existent language, isn't part of my experience during the utterance.

Page 166

I want to exclude from my consideration of familiarity everything that is 'historical'. When that's been done what remains is impressions (experiences, reactions). Even where language does enter into our experience, we don't consider it as an existing institution.

Page 166

So the multiplicity of familiarity, as I understand it, is that of feeling at home in what I see. It might consist in such facts as these: my glance doesn't move restlessly (inquiringly) around the object. I don't keep changing the way I look at it, but immediately fix on one and hold it steady.

Page 166

I see the picture of a heavy coat and have a feeling of warmth and cosiness; I see the picture of a winter landscape and shiver. These reactions, it might be said, are justified by earlier experience. But we aren't concerned *now* about the history of our experiences or about any such justification.

Page 166

No one will say that every time I enter a room, my long familiar surroundings, there is enacted a recognition of all that I see and have seen hundreds of times before.

Page 166

117 If we think of our understanding of a picture, of a genre

Page Break 167

picture say, we are perhaps inclined to assume that there is a particular phenomenon of recognition and that we recognize the painted people as people, the painted trees as trees and so on.

Page 167

But when I look at a genre picture do I compare the painted people with real people etc.?

Page 167

So should I say that I recognize the painted people as painted people? And similarly real people as real people?

Page 167

Of course there is a phenomenon of recognition in a case where it takes some sort of investigation to recognize a drawing as a representation of a human being; but when I see a drawing immediately as the representation of a human being, nothing of that kind happens.

Page 167

A picture of a human face is a no less familiar object than the human face itself. But there is no question of recognition here.

118 It is easy to have a false concept of the processes called "recognizing"; as if recognizing always consisted in comparing two impressions with one another. It is as if I carried a picture of an object with me and used it to perform an identification of an object as the one represented by the picture. Our memory seems to us to be the agent of such a comparison, by preserving a picture of what has been seen before, or by allowing us to look into the past (as if down a spy-glass).

In most cases of recognition no such process takes place.

Someone meets me in the street and my eyes are drawn to his face; perhaps I ask myself "who is that?"; suddenly the face begins to look different in a particular way, "it becomes familiar to me"; I smile, go up to him and greet him by name; then we talk of the past and while we do so perhaps a memory image of him comes before my mind, and I see him in a particular situation.

Perhaps someone will say: if I hadn't kept his image in my memory, I couldn't have recognized him. But here he is either using a metaphor, or expressing a hypothesis.

One might say: "What I saw was memory-laden."

We say: "we couldn't use words at all, if we didn't recognize them and the objects they denote." If (because of a faulty memory) we didn't recognize the colour green for what it is then we couldn't use the word "green". But have we any sort of check on this recognition, so that we know that it is really a recognition? If we speak of recognition, we mean that we recognize something as what, in accordance with other criteria, it is. "To recognize" means "to recognize what *is*".

119 Familiarity gives confirmation to what we see, but not by comparing it with anything else. It gives it a stamp, as it were.

On the other hand I would like to say: "what I see here in front of me is not *any old* shape seen in a particular manner: what I see is my shoes, which I know, and not anything else". But here it is just that two forms of expression fight against each other.

This shape that I see--I want to say--is not simply *a* shape; it is one of the shapes I know; it is a shape marked out in advance. It is one of those shapes of which I already had a pattern in me; and only because it corresponds to such a pattern is it this familiar shape. (I as it were carry a catalogue of such shapes around with me, and the objects portrayed in it *are* the familiar ones.)

But my already carrying the pattern round with me would be only a causal explanation of the present impression. It is like saying: this movement is made as easily as if it had been practised.

And it is not so much as if I were comparing the object with a picture set beside it, but as if the object *coincided* with the picture. So I see only one thing, not two.

120 We say: "This face has a quite *particular* expression", and look perhaps for words to characterise it.

Here it is easy to get into that dead-end in philosophy, where one believes that the difficulty of the task consists in this: our having to describe phenomena that are hard to get hold of, the present experience that slips quickly by, or something of the kind. Where we find ordinary language too crude, and it looks as if we were having to do, not with the phenomena of every-day, but with ones that "easily elude us, and in their coming to be and passing away, produce those others as an average effect".

And here one must remember that all the phenomena that now strike us as so remarkable are the very familiar phenomena that don't surprise us in the least when they happen. They don't strike us as remarkable until we

put them in a strange light by philosophizing.

Page 169

121 "What the picture tells me is itself" is what I want to say. That is, its telling me something consists in *its own* structure, in its own forms and colours.

Page 169

It is as if, e.g. "it tells me something" or "it is a picture" meant: it shows a certain combination of cubes and cylinders.

Page 169

"It tells me something" can mean: it narrates something to me, it is a story.

Page 169

It tells me itself, just as a proposition, a story tells me itself.

Page 169

The concept of a narrative picture is surely like that of a genre picture (or a battle scene). If I wanted to explain what a battle

Page Break 170

scene is, I wouldn't need to refer to any reality outside the picture, I would only have to talk about painted men, painted horses, painted cannon and so on.

Page 170

"The picture tells me something": it uses *words*, so to speak: here are eyes, mouth, nose, hands etc. I am comparing the picture to a combination of linguistic forms.

Page 170

The system of language, however, is not in the category of experience. The experiences characteristic of using the system are not the system. (Compare: the meaning of the word "or" and the or-feeling).

Page 170

"Now, that series of signs tells me something; earlier, before I learnt the language, it said nothing to me". Let us suppose what we mean by that is that the sentence is now read with a particular experience. Certainly, before I learnt the language, that series of signs used not to make the same impression on me. Of course, if we disregard the causal element, the impression is quite independent of the system of language.--And there is something in me that is reluctant to say: the sentence's telling me something is constituted by its making this impression on me.

Page 170

"It's only in a language that something is a proposition" is what I want to say.

Page 170

122 'Language' is only languages, plus things I invent by analogy with existing languages. Languages *are* systems.

Page 170

"A proposition belongs to a language." But that just means: it is units of languages that I call "propositions".

Page 170

But we must pay attention to the *use* of the expression "English language", otherwise we shall ask questions like "What is the language? Is it all the sentences which have so far been spoken? Or the set of rules and words? etc. etc." What is the system? Where is it? What is chess? All the games that have been played? The list of rules?

Page 170

"A *proposition* is a unit of language." "After all, what constitutes

Page Break 171

propositions is the combination of words which might be otherwise combined." But that means: what constitutes propositions *for me*. That is the way I regard language.

Page 171

What *we* want to attend to is the system of language.

Page 171

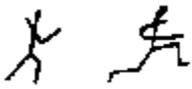

123 Certainly I read a story and don't give a hang about any system of language. I simply read, have impressions, see pictures in my mind's eye, etc. I make the story pass before me like pictures, like a cartoon story. (Of course I do not mean by this that every sentence summons up one or more visual images, and that that is, say, the purpose of a sentence.)

Page 171

Let us imagine a picture story in schematic pictures, and thus more like the narrative in a language than a series of realistic pictures. Using such a picture-language we might in particular e.g. keep our hold on the course of battles. (Language-game.) And a sentence of our word-language approximates to a picture in this picture language

much more closely than we think.

Page 171

Let us remember too that we don't have to translate  such pictures into realistic ones in order to 'understand' them, any more than we ever translate photographs or film pictures into coloured pictures, although black-and-white men or plants in reality would strike us as unspeakably strange and frightful.

Page 171

Suppose we were to say at this point: "Something is a picture only in a picture-language"?

Page 171

A sentence in a story gives us the same satisfaction as a picture.

Page 171

124 We can on the other hand imagine a language in whose use the impression made on us by the signs played no part; in which there was no question of an understanding, in the sense of such an impression. The signs are e.g. written and transmitted to us and we are able to *take notice of them*. (That is to say, the only impression that comes in here is the pattern of the sign.) If the sign is an order,

Page Break 172

we translate it into action by means of rules, tables. It does not get as far as an impression like that of a picture; nor are stories written in this language. But there is perhaps a kind of reading for entertainment which consists in certain series of signs being translated into bodily movements to make a kind of dance. (Compare the remark about translation and code.)

Page 172

In this case one really might say "the series of signs is *dead* without the system".

Page 172

We could of course also imagine that we had to use rules and translate a verbal sentence into a drawing in order to get an *impression* from it. (That only the picture had a soul.)

Page 172

(I might say to my pupils: When you have been through these exercises you will think differently.)

Page 172

But even in our normal speech we may often quite disregard the impression made by a sentence so that all that is important is how we operate with the sentence (Frege's conception of logic).

Page 172

"There is no such thing as an isolated proposition." For what I call a "proposition" is a position in the game of language.

Page 172

Isn't what misleads us the fact that I can look ever so closely at a position in a game without discovering that it is *a position in a game*? What misleads us here is something in the grammar of the expression "position in a game".

Page 172

Thinking is an activity, like calculating. No one would call calculating, or playing chess, a state.

Page 172

125 Let us imagine a kind of puzzle picture: there is not *one* particular object to find; at first glance it appears to us as a jumble

Page Break 173

of meaningless lines, and only after some effort do we see it as, say, a picture of a landscape.--What makes the difference between the look of the picture before and after the solution? It is clear that we see it differently the two times. But what does it amount to to say that after the solution the picture means something to us, whereas it meant nothing before?

Page 173

We can also put this question like this: What is the general mark of the solution's having been found?

Page 173

I will assume that as soon as it is solved I make the solution obvious by strongly tracing certain lines in the puzzle picture and perhaps putting in some shadows. Why do you call the picture you have sketched in a solution?

Page 173

a) Because it is the clear representation of a group of spatial objects.

Page 173

b) Because it is the representation of a regular solid.

Page 173

c) Because it is a symmetrical figure.

Page 173

d) Because it is a shape that makes an ornamental impression on me.

Page 173

e) Because it is the representation of a body I am familiar with.

Page 173

f) Because there is a list of solutions and this shape (this body) is on the list.

Page 173

g) Because it represents a kind of object that I am very familiar with; for it gives me an instantaneous impression of familiarity, I instantly have all sorts of associations in connexion with it; I know what it is called; I know I have often seen it; I know what it is used for etc.

Page 173

h) Because it represents a face which strikes me as familiar.

Page 173

i) Because it represents a face which I recognize: α) it is the face of my friend so and so; β) it is a face which I have often seen pictures of.

Page 173

k) Because it represents an object which I remember having seen at some time.

Page 173

l) Because it is an ornament that I know well (though I don't remember where I have seen it).

Page Break 174

Page 174

m) Because it is an ornament that I know well; I know its name, I know where I have seen it.

Page 174

n) Because it represents part of the furniture of my room.

Page 174

o) Because I instinctively traced out those lines and now feel easy.

Page 174

p) Because I remember that this object has been described.

Page 174

q) Because I seem to be familiar with the object, a word occurs to me at once as its name (although the word does not belong to any existent language); I tell myself "of course, that is an α such as I have often seen in β ; one γ δ 's with it until they ϵ ." Something of the kind occurs e.g. in dreams.

Page 174

And so on.

Page 174

(Anyone who does not understand why we talk about these things must feel what we say to be mere trifling.)

Page 174

126 The impression is one thing, and the impression's being determinate is another thing. What I call the impression of familiarity is as multifarious as being determinate is.

Page 174

When we look into a human face that we know very well, we need not have any impression, our wits may be completely dull, so to speak; and between that case and a strong impression there are any number of stages.

Page 174

Suppose the sight of a face has a strong effect on us, inspiring us say with fear. Am I to say: first of all there must occur an impression of familiarity, the form of the human face as such must make an impression of familiarity on me, and only then is the impression of fear added to that impression?--Isn't it like this, that what I call the impression of specific familiarity is a characteristic of every strong impression that a face makes on me?--The characteristic, say of determinacy. I did indeed say that the impression of familiarity consists in things like our feeling at home in what we see, in our not changing our way of looking and the like.

Page Break 175

Page 175

127 Can I think away the impression of individual familiarity where it exists; and think it into a situation where it

does not? And what does that mean? I see e.g. the face of a friend and ask myself: what does this face look like if I see it as an unfamiliar face (as if I were seeing it now for the first time)? What remains, as it were, of the look of this face, if I think away, subtract, the impression of familiarity from it? Here I am inclined to say: "It is *very difficult* to separate the familiarity from the impression of the face." But I also feel that this is a misleading way of putting things. For I have no notion how I should so much as try to separate these two things. The expression "to separate them" does not have any clear sense for me.

Page 175

I know what *this means*: "Imagine this table black instead of brown"; it means something like: "paint a picture of this table, but black instead of brown"; or similarly: "draw this man but with longer legs than he has".

Page 175

Suppose someone were to say "Imagine this butterfly exactly as it is, but ugly instead of beautiful"?!

Page 175

"It is very difficult to think away ... ": here it looks as if it was a matter of a psychological difficulty, a difficulty of introspection or the like. (That is true of a large range of philosophical problems: think of the problem of the exact reproduction or description of what is seen in the visual field; of the description of the perpetual flux of phenomena; also of "how many raindrops do you see, if you look at the rain?")

Page 175

Compare: "It is difficult *to will* that table to move from a distance."

Page 175

In this case *we* have not *determined* what thinking the familiarity away is to mean.

Page 175

It might mean, say, to recall the impression which I had when I saw the face for the first time. And here again one must know what it means to "*try*" to remember the impression. For that has several meanings. Let us ask ourselves what activities we call

Page Break 176

"trying to remember something". What do we do if we want to remember what we had for lunch yesterday? Is that method available for the early memories of an adult? Can one *try* to remember one's own birth?

Page 176

I tell myself: I want to try to look at a printed English word and see it as if I hadn't learnt to read, as if the black shapes on the paper were strange drawings whose purpose I couldn't imagine or guess. And then what happens is that I can't look at the printed word without the sound of the word or of the letter I'm actually looking at coming before my mind.

Page 176

For someone who has no knowledge of such things a diagram representing the inside of a radio receiver will be a jumble of meaningless lines. But if he is acquainted with the apparatus and its function, that drawing will be a significant picture for him.

Page 176

Given some solid figure (say in a picture) that means nothing to me at present--can I at will imagine it as meaningful? That's as if I were asked: Can I imagine a body of any old shape as an appliance? But for what sort of use?

Page 176

Well, at any rate one class of corporeal shapes can readily be imagined as dwellings for beasts or men. Another class as weapons. Another as models of landscapes. Etc. etc. So here I know how I can ascribe meaning to a meaningless shape.

Page 176

128 If I say that this face has an expression of gentleness, or kindness, or cowardice, I don't seem just to mean that we associate such and such feelings with the look of the face, I'm tempted to say that the face is itself one aspect of the cowardice, kindness, etc. (Compare e.g. Weininger). It is possible to say: I see cowardice in this face (and might see it in another too) but at all events it doesn't seem to be merely associated, outwardly connected, with the face;

Page Break 177

the fear has the multiplicity of the facial features. And if, for example, the features change slightly, we can speak of a corresponding change in the fear. If we were asked "Can you think of this face as an expression of courage too?"--we should, as it were, not know how to lodge courage in these features. Then perhaps I say "I don't know what it would mean if this is a courageous face." [This sentence cannot be corrected by saying "for this to be a courageous face" instead of "if this is a courageous face"].†1 But what would an answer to such a question be like?

Perhaps one says: "Yes, now I understand: the face as it were shews indifference to the outer world." So we have somehow read courage into the face. Now once more, one might say, courage *fits* this face. But *what* fits *what* here?

Page 177

There is a related case (though perhaps it will not seem so) when for example we (Germans) are surprised that the French do not simply say "the man is good" but put an attributive adjective where there should be a predicative one; and when we solve the problem for ourselves by saying: they mean: "the man is *a good one*".

Page 177

Couldn't different interpretations of a facial expression consist in my imagining each time a different kind of sequel? Certainly that's often how it is. I see a picture which represents a smiling face. What do I do if I take the smile now as a kind one, now as malicious? Don't I imagine it with a spatial and temporal context which I call kind or malicious? Thus I might supply the picture with the fancy that the smiler was smiling down at a child at play, or again on the suffering of an enemy.

Page 177

This is in no way altered by the fact that I can also take the at first sight gracious situation and interpret it differently by putting it into a wider context.--If no special circumstances reverse my interpretation I shall conceive a particular smile as kind, call it a "kind" one, react correspondingly.

Page Break 178

Page 178

That is connected with the contrast between *saying* and *meaning*.

Page 178

"Any expression can lie": but you must think what you mean by "lie". How do you imagine a lie? Aren't you contrasting one expression with another? At any rate, you are contrasting with the expression some other process which might very well be an expression.

Page 178

129 What does it mean: "to *read* kindness *into* the smile"? Perhaps it means: I make a face which is coordinated with the smiling face in a particular way. I coordinate my face to the other one in some such way as to exaggerate one or other of its features.

Page 178

A friendly mouth, friendly eyes. How would one think of a friendly hand? Probably open and not as a fist.--And could one think of the colour of a man's hair as an expression of friendliness or the opposite? Put like that the question seems to ask whether we can *manage* to. The question ought to run: Do we want to call anything a friendly or unfriendly hair-colour? If we wanted to give such words a sense, we should perhaps imagine a man whose hair darkened when he got angry. The reading of an angry expression into dark hair, however, would work *via* a previously existent conception.

Page 178

It may be said: the friendly eyes, the friendly mouth, the wagging of a dog's tail, are among the primary and mutually independent symbols of friendliness; I mean: They are parts of the phenomena that are called friendliness. If one wants to imagine further appearances as expressions of friendliness, one reads these symbols into them. We say: "He has a black look", perhaps because the eyes are more strongly shadowed by the eyebrows; and now we transfer the idea of darkness to the colour of the hair. He has glowering hair. If I were asked whether I could imagine a chair with a friendly expression, it would be above all a friendly *facial expression* I would want to imagine it with; I would want to read a friendly *face* into it.

Page Break 179

Page 179

I say "I can think of this face (which *at first* gives an impression of timidity) as courageous too." We *do not mean* by this that I can imagine someone with this face perhaps saving someone's life (that, of course, is imaginable in connexion with any face). I am speaking rather of an aspect of the face itself. Nor do I mean that I can imagine that this man's face might change so that, in the ordinary sense, it looked courageous; though I may very well mean that there is quite a definite way in which it can change into a courageous face. The reinterpretation of a facial expression can be compared with the reinterpretation of a chord in music, when we hear it as a modulation first into this, then into that key. (Compare also the distinction between mixed colours and intermediary colours).

Page 179

Suppose we ask ourselves "what proper name would suit the character of this man"--and portray it in sound? The method of projection we use for the portrayal is something which as it were stands firm. (A writer might ask

himself what name he wants to give to a person.) But sometimes we project the character into the name that has been given. Thus it appears to us that the great masters have names which uniquely fit the character of their works.

Page 179

Experience of the real size. Suppose we saw a picture showing a chair-shape; we are told it represents a construction the size of a house. Now we see it differently.

Page 179

What happens when we learn to feel the ending of a church mode as an ending?

Page 179

Think of the multifariousness of what we call "language". Word-language, picture-language, gesture-language, sound-language.

Page 179

130 "'This object is familiar to me' is like saying 'this object is portrayed in my catalogue'." In that case it would consist in the fact that it was a picture filed with others in a particular folder, in *this* drawer. But if that really is what I imagine--if I think I simply

Page Break 180

compare the seen object with pictures in my catalogue and find it to agree with one of them--it is something quite unlike the phenomenon of familiarity. That is, we are making the assumption that the picture in our catalogue is itself familiar. If it were something strange, then the fact that it was in this folder, in this drawer, would mean nothing to us.

Page 180

When I speak of a pattern in my mental catalogue, or of a sheath into which an object fits if it is familiar, what I would like to say is that the sheath in my mind is, as it were, the "form of imagining", so that it isn't possible for me to say of a pattern that it is in my mind unless it really is there.--The pattern as it were retires into my mind, so that it is no longer presented to it as an object. But that only means: it didn't make sense to talk of a pattern at all. (The spatial spectacles we can't take off.)

Page 180

If we represent familiarity as an object's fitting into a sheath, that's not quite the same as our *comparing* what is seen with a copy. What we really have in mind is the feeling when the object slips smoothly into the contour of the sheath. But that is a feeling we might have even if there were no such perfectly fitting sheath there at all.

Page 180

We might also imagine that every object had an invisible sheath; that alters nothing in our experience, it is an empty form of representation.

Page 180

It shouldn't really be "Yes, I recognize it, it's a face" but "I recognize it, I see a face". (Here the word face

might mean for me the mere ornament and have no reference to the human face; it might be on a level with any other familiar figure, e.g. a swastika.) For the question is: "What do I recognize *as what*?" For "to recognize a thing as itself" is meaningless.

Page Break 181

Page 181

131 The comparison between memory and a notebook. On the one hand this comparison serves as a picture of the conscious phenomena, and on the other hand it provides a psychological model. (And the word "conscious" is a reference to a chapter of the grammar and is not one side of the psychological contrast between "conscious" and "unconscious".)

Page 181

Many very different things happen when we remember.

Page 181

"Have you been in your room?" "Yes". "Are you sure?" "I would know if I hadn't been here yesterday!" For this I don't need to see myself, even for a moment, in memory in my room. But let's assume that when I said that I saw myself standing at the window in my room; how does the picture show me that it was yesterday? Of course, the picture could show that as well, if for instance I saw in it a wall-calendar with yesterday's date. But if that wasn't the case, how did I read off from the memory image, or from the memory, that I stood thus at the window *yesterday*? How do I translate the experience of remembering into words?--But did I translate an experience into words? Didn't I just utter the words in a particular tone of voice with other experiences of certainty? But wasn't that the experience

of remembering? (The experience of translating is the same kind of thing as the experience of the tone of voice.) But what made you so certain when you spoke those words? Nothing *made* me certain; I *was* certain.

Page 181

Of course, I have other ways of checking--as one might say--what I then uttered. That is: I can now try to remember particular things that happened yesterday and to call up pictures before my mind's eye etc. But certainly that didn't *have* to have happened before I answered.

Page 181

When we narrate a set of events from memory we do sometimes see memory pictures in our mind; but commonly they are only scattered through the memory like illustrations in a story book.

Page 181

Someone says to me "Imagine a patch of the colour called 'red' on this white wall". I do so--shall I now say that I *remembered*

Page Break 182

which colour is called 'red'? When I talk about this table, do I remember that this object is called a 'table'?

Page 182

Mightn't someone object: "So if a man has not learned a language is he unable to have certain memories?" Of course--he cannot have verbal memories, verbal wishes and so on. And memories etc. in language are not mere threadbare representations of the real experiences; for is what is linguistic not an experience? (Words are deeds.)

Page 182

Some men recall a musical theme by having an image of the score rise before them, and reading it off.

Page 182

It could be imagined that what we call "memory" in some man consisted in his seeing himself looking things up in a notebook in spirit, and that what he read in that book was what he remembered. (How do I *react* to a memory?)

Page 182

Incidentally, when I treat the objects around me as familiar, do I think of that comparison? Of course not. I only do so when I look at the act of recognition (individual recognition) after the event; and not so much when I look at it to see what actually happened, as when I look at it through a preconceived schema. (The flux of time.)†1

Page 182

132 If one takes it as obvious that a man takes pleasure in his own fantasies, let it be remembered that fantasy does not correspond to a painted picture, to a sculpture or a film, but to a complicated formation out of heterogeneous components--words, pictures, etc. Then one will not contrast operating with written and spoken

Page Break 183

signs with operating with "imagination-pictures" of events.

Page 183

(The ugliness of a human being can repel in a picture, in a painting, as in reality, but so it can too in a description, in words.)

Page 183

Attitude to a picture (to a thought). The way we experience a picture makes it real for us, that is, connects it with reality; it establishes a continuity with reality.

Page 183

(Fear connects a picture with the terrors of reality.)

Page Break 184

X

Page 184

133 Can an ostensive definition come into collision with the other rules for the use of a word?--It might appear so; but rules can't collide, unless they contradict each other. That aside, it is they that determine a meaning; there isn't a meaning that they are answerable to and could contradict.

Page 184

Grammar is not accountable to any reality. It is grammatical rules that determine meaning (constitute it) and so they themselves are not answerable to any meaning and to that extent are arbitrary.

Page 184

There cannot be a question whether these or other rules are the correct ones for the use of "not" (that is,

whether they accord with its meaning). For without these rules the word has as yet no meaning; and if we change the rules, it now has another meaning (or none), and in that case we may just as well change the word too.

Page 184

"The only correlate in language to an intrinsic necessity is an arbitrary rule. It is the only thing which one can milk out of this intrinsic necessity into a proposition."†1

Page 184

Why don't I call cookery rules arbitrary, and why am I tempted to call the rules of grammar arbitrary? Because I think of the concept "cookery" as defined by the end of cookery, and I don't think of the concept "language" as defined by the end of language. You cook badly if you are guided in your cooking by rules other than the right ones; but if you follow other rules than those of chess you are playing another game; and if you follow grammatical

Page Break 185

rules other than such and such ones, that does not mean you say something wrong, no, you are speaking of something else.

Page 185

If I want to carve a block of wood into a particular shape any cut that gives it the right shape is a good one. But I don't call an argument a good argument just because it has the consequences I want (Pragmatism). I may call a calculation wrong even if the actions based on its result have led to the desired end. (Compare the joke "I've hit the jackpot and he wants to give me lessons!"†1) That shows that the justifications in the two cases are different, and also that "justification" means something different in each case. In the one case one can say "Just wait, you will soon see that it will come out right (i.e. as desired)". In the other case that is no justification.

Page 185

The connection between the rules of cookery and the grammar of the word "cook" is not the same as that between the rules of chess and the expression "play chess" or that between the rules of multiplication and the grammar of the word "multiply".

Page 185

The rules of grammar are arbitrary in the same sense as the choice of a unit of measurement. But that means no more than that the choice is independent of the length of the objects to be measured and that the choice of one unit is not 'true' and of another 'false' in the way that a statement of length is true or false. Of course that is only a remark on the grammar of the word "unit of length".

Page 185

134 One is tempted to justify rules of grammar by sentences like "But there are really four primary colours". And if we say that the

Page Break 186

rules of grammar are arbitrary, that is directed against the possibility of this justification. Yet can't it after all be said that the grammar of colour words characterizes the world as it actually is? One would like to say: May I not really look in vain for a fifth primary colour? (And if looking is possible, then finding is conceivable.) Doesn't grammar put the primary colours together because there is a kind of similarity between them? Or colours, anyway, in contrast to shapes or notes? Or, when I set this up as the right way of dividing up the world, have I a preconceived idea in my head as a paradigm? Of which in that case I can say: "Yes, that is the way we look at things" or "We just do want to form this sort of picture." For if I say "there is a particular similarity among the primary colours"--whence do I derive the idea of this similarity? Just as the idea 'primary colour' is nothing else but 'blue or red or green or yellow' is not the idea of that similarity too given simply by the four colours? Indeed, aren't these concepts the same? (For here it can be said: "what would it be like if these colours did not have this similarity?") (Think of a group containing the four primary colours plus black and white, or the visible colours plus ultraviolet and infrared.)

Page 186

I do not call rules of representation conventions if they can be justified by the fact that a representation made in accordance with them will agree with reality. For instance the rule "paint the sky brighter than anything that receives its light from it" is not a convention.

Page 186

The rules of grammar cannot be justified by shewing that their application makes a representation agree with reality. For this justification would itself have to describe what is represented. And if something can be said in the justification and is permitted by its grammar--why shouldn't it also be permitted by the grammar that I am trying to

justify? Why shouldn't both forms of expression

Page Break 187

have the same freedom? And how could what the one says restrict what the other can say?

Page 187

But can't the justification simply *point* to reality?

Page 187

How far is such pointing a justification? Does it have the multiplicity of a justification? Of course it may be the cause of our saying one sentence rather than another. But does it give a reason for it? Is *that* what we call a justification?

Page 187

No one will deny that studying the nature of the rules of games must be useful for the study of grammatical rules, since it is beyond doubt there is some sort of similarity between them.--The right thing is to let the certain instinct that there is a kinship lead one to look at the rules of games without any preconceived judgement or prejudice about the analogy between games and grammar. And here again one should simply report what one sees and not be afraid that one is undermining a significant and correct intuition, or, on the other hand, wasting one's time with something superfluous.

Page 187

135 One can of course consider language as part of a psychological mechanism. The simplest case is if one uses a restricted concept of language in which language consists only of commands.

Page 187

One can then consider how a foreman directs the work of a group of people by shouting.

Page 187

One can imagine a man inventing language, imagine him discovering how to train other human beings to work in his place, training them through reward and punishment to perform certain tasks when he shouts. This discovery would be like the invention of a machine.

Page 187

Can one say that grammar describes language? If we consider language as part of the psycho-physical mechanism which we use

Page Break 188

when we utter words--like pressing keys on a keyboard--to make a human machine work for us, then we can say that grammar describes that part of the machine. In that case a correct language would be one which would stimulate the desired activities.

Page 188

Clearly I can establish by experience that a human being (or animal) reacts to one sign as I want him to, and to another not. That e.g. a human being goes to the right at the sign "→" and goes to the left at the sign "←"; but that

he does not react to the sign "" as to "←".

Page 188

I do not even need to fabricate a case, I have only to consider what is in fact the case; namely, that I can direct a man who has learned only German, only by using the German language. (For here I am looking at learning German as adjusting (conditioning) a mechanism to respond to a certain kind of influence; and it may be all one to us whether someone else has learned the language, or was perhaps from birth constituted to react to sentences in German like a normal person who has learned it.)

Page 188

Suppose I now made the discovery that someone would bring me sugar at a sign plus the cry "Su", and would bring me milk at a sign and the cry "Mi", and would not do so in response to other words. Should I say that this shows that "Su" is the correct (the only correct) sign for sugar, "Mi" the correct sign for milk?

Page 188

Well, if I say that, I am not using the expression "sign for sugar" in the way it is ordinarily used or in the way I intended to use it.

Page 188

I do not use "that is the sign for sugar" in the same way as the sentence "if I press this button, I get a piece of sugar".

Page 188

136 All the same, let us compare grammar with a system of buttons, a keyboard which I can use to direct a man or a

machine by pressing

Page Break 189

different combinations of keys. What corresponds in this case to the grammar of language?

Page 189

It is easy to construct such a keyboard, for giving different "commands" to the machine. Let's look at a very simple one: it consists of two keys, the one marked "go" and the other "come". Now one might think it must obviously be a rule of the grammar that the two keys shouldn't be depressed simultaneously (that would give rise to a contradiction). But what does happen if we press them both at the same time? Am I assuming that this has an effect? Or that it has no effect? In each case I can designate the effect, or the absence of an effect, as the point and sense of the simultaneous depression of both keys.

Page 189

Or: When I say that the orders "Bring me sugar" and "Bring me milk" make sense, but not the combination "Milk me sugar", that does not mean that the utterance of this combination of words has no effect. And if its effect is that the other person stares at me and gapes, I don't on that account call it the order to stare and gape, even if *that* was precisely the effect that I wanted to produce.

Page 189

"This combination of words makes no sense" does not mean it has no effect.

Page 189

Not even "it does not have the desired effect".

Page 189

137 To say "This combination of words makes no sense" excludes it from the sphere of language and thereby bounds the domain of language. But when one draws a boundary it may be for various kinds of reasons. If I surround an area with a fence or a line or otherwise, the purpose may be to prevent someone from getting in or out; but it may also be part of a game, and the players be supposed, say, to jump over the boundary; or it may show where A's property ends and B's begins; and so on. So if I draw a boundary line that is not yet to say what I am drawing it for.

Page Break 190

Page 190

Language is not defined for us as an arrangement fulfilling a definite purpose. Rather "language" is for me a name for a collection and I understand it as including German, English, and so on, and further various systems of signs which have more or less affinity with these languages.

Page 190

Language is of interest to me as a phenomenon and not as a means to a particular end.

Page 190

138 Grammar consists of conventions. An example of such conventions be one saying "the word 'red' means this colour". Such a convention may be included say in a chart.--Well, now, how could a convention find a place in a mechanism (like the works of a pianola?) Well, it is quite possible that there is a part of the mechanism which resembles a chart, and is inserted between the language-like part of the mechanism and the rest of it.

Page 190

Of course an ostensive definition of a word sets up a connection between a word and 'a thing', and the purpose of this connection may be that the mechanism of which our language is a part should function in a certain way. So the definition can make it work properly, like the connection between the keys and the hammers in a piano; but the connection doesn't consist in the hearing of the words now having *this* effect, since the effect may actually be caused by the making of the convention. And it is the connection and not the effect which determines the meaning.

Page 190

When someone is taught language, does he learn at the same time what is sense and nonsense? When he uses language to what extent does he employ grammar, and in particular the distinction between sense and nonsense?

Page Break 191

Page 191

When someone learns musical notation, he is supplied with a kind of grammar. This is to say: this note corresponds to this key on the piano, the sign \sharp sharpens a note, the sign \natural cancels the \sharp etc. etc. If the

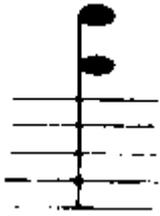

pupil asked whether there was a distinction between

and

or what the sign

meant, we would tell him that the distance between the top of the note and the staff didn't mean anything, and so on. One can view this instruction as part of the preparation that makes the pupil into a playing-machine.

Page 191

So he can speak of a grammar in the case where a language is taught to a person by a mere drill? It is clear that if I want to use the word "grammar" here I can do so only in a "degenerate" sense, because it is only in a degenerate sense that I can speak of "explanation", or of "convention".

Page 191

And a trained child or animal is not acquainted with any problems of philosophy.

Page 191

139 When I said that for us a language was not something that achieved a particular end, but a concept defined by certain systems we call "languages" and such systems as are constructed by analogy with them--I could also have expressed the same thing in the following way: causal connections in the mechanism of language are things that I don't scruple to *invent*.

Page 191

Imagine that someone were to explain "Language is whatever one can use to communicate". What constitutes communication? To complete the explanation we should have to describe what happens when one communicates; and in the process certain causal connections and empirical regularities would come out. But these are just the things that wouldn't interest me; they are the kinds of

Page Break 192

connection I wouldn't hesitate to make up. I wouldn't call just anything that opened the door a "key-bit", but only something with a particular form and structure.

Page 192

"Language" is a word like "keyboard". There are machines which have keyboards. For some reason or other I might be interested in forms of keyboard (both ones in actual use and others merely devised by myself). And to invent a keyboard might mean to invent something that had the desired effect; or else to devise new forms which were similar to the old ones in various ways.

Page 192

"It is always for living beings that signs exist, so that must be something essential to a sign." Yes, but how is a "living" being defined? It appears that here I am prepared to use its capacity to use a sign-language as a defining mark of a living being.

Page 192

And the concept of a living being really has an indeterminacy very similar to that of the concept "language".

Page 192

140 To invent a language could mean to invent an instrument for a particular purpose on the basis of the laws of nature (or consistently with them); but it also has the other sense, analogous to that in which we speak of the invention of a game.

Page 192

Here I am stating something about the grammar of the word "language" by connecting it with the grammar

of the word "invent".

Page 192

Are the rules of chess arbitrary? Imagine that it turned out that only chess entertained and satisfied people. Then the rules aren't arbitrary if the purpose of the game is to be achieved.

Page 192

"The rules of a game are arbitrary" means: the concept 'game' is not defined by the effect the game is supposed to have on us.

Page Break 193

Page 193

There is an analogous sense in which it is arbitrary which unit of measurement we use to express a length, and another sense in which the choice of units is limited or determined.

Page 193

For us language is a calculus; it is characterized by *linguistic activities*.

Page 193

Where does language get its significance? Can we say "Without language we couldn't communicate with one another"? No. It's not like "without the telephone we couldn't speak from Europe to America". We can indeed say "without a mouth human beings couldn't communicate with each other". But the concept of language *is contained in* the concept of communication.

Page 193

141 Is philosophy a creation of word-language? Is word-language a necessary condition for the existence of philosophy? It would be more proper to ask: is there anything like philosophy outside the region of our word-languages? For philosophy isn't anything except philosophical problems, the particular individual worries that we call "philosophical problems". Their common element extends as far as the common element in different regions of our language.

Page 193

Let us consider a particular philosophical problem, such as "How is it possible to measure a period of time, since the past and the future aren't present and the present is only a point?" The characteristic feature of this is that a confusion is expressed in the form of a question that doesn't acknowledge the confusion, and that what *releases* the questioner from his problem is a particular alteration of his method of expression.

Page 193

I could imagine an organ whose stops were to be operated by keys distributed among the keys of the manual which looked exactly like them. There might then arise a philosophical problem: "How are silent notes possible?" And the problem would be

Page Break 194

solved by someone having the idea of replacing the stop-keys by stops which had no similarity with the note-keys.

Page 194

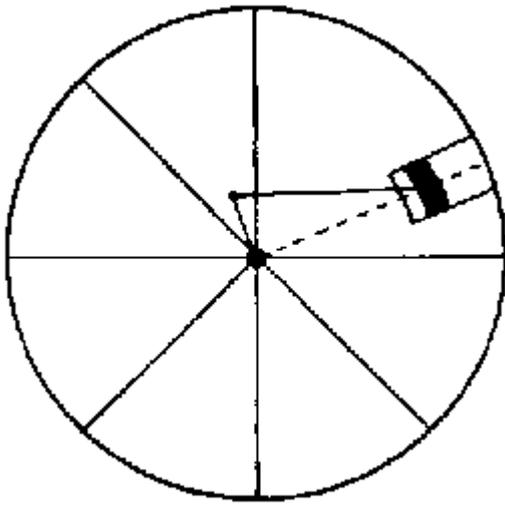

A problem or worry like a philosophical one might arise because someone *played* on all the keys of the manual, and the result didn't sound like music, and yet he was tempted to think that it must be music etc.

Page 194

(Something that at first sight looks like a sentence and is not one.)

Page 194

The following design for the construction of a steam roller was shown to me and seems to be of philosophical interest. The inventor's mistake is akin to a philosophical mistake. The invention consists of a motor inside a hollow roller. The crank-shaft runs through the middle of the roller and is connected at both ends by spokes with the wall of the roller. The cylinder of the petrol-engine is fixed onto the inside of the roller. At first glance this construction looks like a machine. But it is a rigid system and the piston cannot move to and fro in the cylinder. Unwittingly we have deprived it of all possibility of movement.

Page 194
 142 "Could a language consist simply of independent signals?" Instead of this we might ask: Are we willing to call a series of independent signals "a language"? To the question "can such a language achieve the same as one which consists of sentences, or combinations of signs?" one would have to answer: it is *experience*

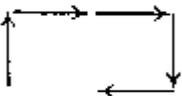

Page Break 195
 that will show us whether e.g. these signals have the same effect on human beings as sentences. But the effect is of no interest to us; we are looking at the phenomenon, the calculus of language.

Page 195
 Imagine something like a diary kept with signals. One side is divided into sections for the hours of the day, like a timetable. The sign "A" means: I am sleeping; "B" means "I am working"; "C" I am eating, etc. etc. But now the question is: are explanations like this given, so that the signals are connected to another language? Is the signal-language supplemented with ostensive definitions of the signals? Or is the language really only to consist of the signs A, B, C etc.?

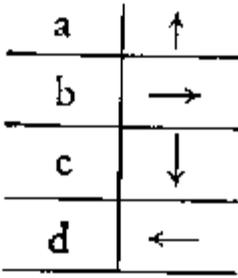

Page 195
 Suppose someone asked: "how do you know, that you are now doing the same as you were an hour ago?", and I answered: "I wrote it down, yes, here there's a 'C'"--Can one ask whether the sign "A" always means the same? In what circumstances can this question be answered one way or the other? (One can imagine a language in which the words, the names of the colours, say, changed their meanings with the day of the week; this colour is called "red" on Monday, "blue" on Tuesday. "A = A" might say that in the language to which this rule applies there is no change in the meaning of the sign "A".)

Page 195
 Imagine again a language consisting of commands. It is to be used to direct the movements of a human being; a command specifies the distance, and adds one of the words "forwards", "backwards", "right" and "left" and one of the words "fast" and "slowly". Now of course all the commands which will actually be used to direct the movements of a human being; a command such signals in the first place as abbreviations of the sentences of the first language, perhaps translating them back into it before obeying them, and then later on act immediately in response to the signals.--In that case we might speak of two languages and say the first was more pictorial than the second. That is, we wouldn't

Page Break 196
 say that a series of such signals by itself would enable me to *derive* a picture of the movement of a man obeying them unless in addition to the signal there is something that might be called a general rule for translating into drawing. We wouldn't say: from the sign a b b c d you can *derive* the figure

but we would say that you can derive it from a b b c d plus the table

Page 196

We can say: the grammar *explains* the meaning of the signs and thus makes the language pictorial.

Page 196

I can justify the choice of a word by a grammar. But that doesn't mean that I do, or have to, use definitions to justify the words I use in a description or something similar.

Page 196

A comparable case is when ordinary grammar completes an elliptical sentence, and so takes a particular construction as an abbreviated *sentence*.

Page Break 197

Appendix

Page 197

Page Break 198

Page Break 199

1:

Complex and Fact

Page 199

The use of the words 'fact' and 'act'--'That was a noble act.'--'But, that never happened.'--

Page 199

It is natural to want to use the word 'act' so that it only corresponds to a *true* proposition. So that we then don't talk of an act which was never performed. But the proposition 'That was a noble act' must still have a sense even if I am mistaken in thinking that what I call an act occurred. And that of itself contains all that matters, and I can only make the stipulation that I will only use the words 'fact', 'act' (perhaps also 'event') in a proposition which, when complete, asserts that this fact obtains.

Page 199

It would be better to drop the restriction on the use of these words, since it only leads to confusion, and say quite happily: 'This act was never performed', 'This fact does not obtain', 'This event did not occur'.

Page 199

Complex is not like fact. For I can, e.g., say of a complex that it moves from one place to another, but not of a fact.

Page 199

But that this complex is now situated here is a fact.

Page 199

'This complex of buildings is coming down' is tantamount to: 'The buildings thus grouped together are coming down'.

Page 199

I call a flower, a house, a constellation, complexes: moreover, complexes of petals, bricks, stars etc.

Page 199

That this constellation is located here, can of course be described by a proposition in which only its stars are mentioned and neither the word 'constellation' nor its name occurs.

Page 199

But that is all there is to say about the relation between complex

Page Break 200

and fact. And a complex is a spatial object, composed of spatial objects. (The concept 'spatial' admitting of a certain extension.)

Page 200

A complex is composed of its parts, the things of a kind which go to make it up. (This is of course a grammatical proposition concerning the words 'complex', 'part' and 'compose'.)

Page 200

To say that a red circle is *composed* of redness and circularity, or is a complex with these component parts, is a misuse of these words and is misleading. (Frege was aware of this and told me.)

Page 200

It is just as misleading to say the fact that this circle is red (that I am tired) is a complex whose component parts are a circle and redness (myself and tiredness).

Page 200

Neither is a house a complex of bricks and their spatial relations. i.e. that too goes against the correct use of the word.

Page 200

Now, you can of course point at a constellation and say: this constellation is composed entirely of objects with which I am already acquainted; but you can't 'point at a fact' and say this.

Page 200

'To describe a fact', or 'the description of a fact', is also a misleading expression for the assertion stating that the fact obtains, since it sounds like: 'describing the animal that I saw'.

Page 200

Of course we also say: 'to point out a fact', but that always means; 'to point out the fact that...'. Whereas 'to point at (or point out) a flower' doesn't mean to point out that this blossom is on this stalk; for we needn't be talking about this blossom and this stalk at all.

Page 200

It's just as impossible for it to mean: to point out the fact that this flower is situated there.

Page 200

To point out a fact means to assert something, to state something. 'To point out a flower' doesn't mean this.

Page Break 201

Page 201

A chain, too, is composed of its links, not of these and their spatial relations.

Page 201

The fact that these links are so concatenated, isn't '*composed*' of anything at all.

Page 201

The root of this muddle is the confusing use of the word 'object'.

Page 201

The part is smaller than the whole: applied to fact and component part (constituent), that would yield an absurdity.

Page 201

The schema: thing-property. We say that actions have properties, like swiftness, or goodness.

Page Break 202

2:

Concept and Object, Property and Substrate

Page 202

When Frege and Russell talk of concept and object they really mean property and thing; and here I'm thinking in particular of a spatial body and its colour. Or one can say: concept and object are the same as predicate and subject. The subject-predicate form is one of the forms of expression that occur in human languages. It is the form "x is y" (" $x \in y$ "): "My brother is tall", "The storm is nearby", "This circle is red", "Augustus is strong", "2 is a number", "This thing is a piece of coal".

Page 202

The concept of a material point in physics is an abstraction from the material objects of experience; in the same way the subject-predicate form of logic is an abstraction from the subject-predicate form of our languages. The pure subject-predicate form is supposed to be $a \in f(x)$, where "a" is the name of an object. Now let's look for an application of this schema. The first things that come to mind as "names of objects" are the names of persons and of other spatial objects (the Koh-i-Noor). Such names are given by ostensive definitions ("that  is called 'N'"). Such a definition might be conceived as a rule substituting the word "N" for a gesture pointing to the object, with the proviso that the gesture can always be used in place of the name. Thus, I may have explained "this man is called 'N'", and I go on to say "'N' is a mathematician", "N is lazy", and in each of these sentences I might have said "this man"

(with the ostensive gesture) instead of "N". (In that case, incidentally it would have been better to phrase the ostensive definition "this man is called 'N'"†1 or "I want to call this man 'N'", because the version above is also the proposition that this man bears this name).

Page 202

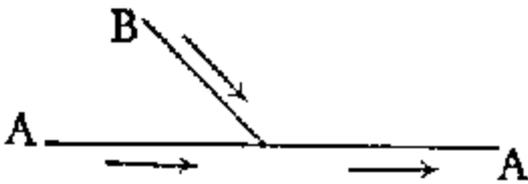

However, this isn't the normal way of using a name; it is an essential feature of the normal use that I can't fall back on to a sign of the gesture language in place of the name. That's to say, in the way in which we use the name "N", if N goes out of the room and later a man comes into the room it makes sense to ask whether

Page Break 203

this man is N, whether he is the same man as the one who left the room earlier. And the sentence "N has come back into the room" only makes sense if I can decide the question. And its sense will vary with the criterion for this being the object that I earlier called 'N'. Different kinds of criteria will make different rules hold for the sign 'N', will make it a 'name' in a different sense of the word. Thus the word 'name' and the corresponding word 'object' are each headings to countless different lists of rules.

Page 203

If we give names to spatial objects, our use of such names depends on a criterion of identity which presupposes the impenetrability of bodies and the continuity of their movement. So if I could treat two bodies A and B as I can treat their shadows on the wall, making two into one and one into two again, it would be senseless to ask which of the two after the division is A and which is B, unless I go on to introduce a totally new criterion of identity e.g. the direction of their movements. (There is a rule for the name of a river arising from the confluence of two rivers, thus:

The resulting river takes the name of that source in whose approximate direction it flows onward.)

Page 203

Think of the possible criteria of identity for things like colour patches in my visual field (or figures on a cinema screen) and of the different kinds of use of names given to such patches or figures.

Page 203

If we turn to the form of expression " $(\exists x).fx$ " it's clear that this is a sublimation of the form of expression in our language: "There are human beings on this island" "There are stars that we do not see". To every proposition of the form " $(\exists x).fx$ " there is supposed to correspond a proposition "fa", and "a" is supposed to be a name. So one must be able to say " $(\exists x).fx$, namely a and b",

Page Break 204

("There are some values of x, which satisfy fx, namely a and b"), or " $(\exists x).fx$, e.g. a", etc. And this is indeed possible in a case like "There are human beings on this island, namely Messrs A, B, C, D." But then is it essential to the sense of the sentence "There are men on this island" that we should be able to name them, and fix a particular criterion for their identification? That is only so in the case where the proposition " $(\exists x).fx$ " is defined as a disjunction of propositions of the form "f(x)", if e.g. it is laid down that "There are men on this island" means "Either Mr. A or Mr. B or Mr. C or Mr. D. or Mr. E is on this island"--if, that is, one determines the concept "man" extensionally (which of course is quite contrary to the normal use of this word.) (On the other hand the concept "primary colour" really is determined extensionally.)

Page 204

So it doesn't always make sense when presented with a proposition " $(\exists x).fx$ " to ask "Which xs satisfy f?" "Which red circle a centimetre across is in the middle of this square?"--One mustn't confuse the question "which object satisfies f?" with the question "what sort of object... etc.?" The first question would have to be answered by a name, and so the answer would have to be able to take the form "f(a)"; the question "what sort of...?" is answered by " $(\exists x).fx.\phi x$ ". So it may be senseless to ask "which red spot do you see?" and yet make sense to ask "what kind of a red spot do you see (a round one, a square one, etc.)?"

Page 204

I would like to say: the old logic contains more convention and physics than has been realised. If a noun is

the name of a *body*, a verb is to denote a movement, and an adjective to denote a property of a body, it is easy to see how much that logic presupposes; and it is reasonable to conjecture that those original presuppositions go still deeper into the application of the words, and the logic of propositions.

Page 204

(Suppose we were set the task of projecting figures of various shapes on a given plane I into a plane II. We could then fix a

Page Break 205

method of projection (say orthogonal projection) and carry out the mapping in accordance with it. We could also easily make inferences from the representations on plane II about the figures on plane I. But we could also adopt another procedure: we might decide that the representations in the second plane should all be circles, no matter what the copied figures in the first plane might be. (Perhaps this is the most convenient form of representation for us.) That is, different figures on I are mapped onto II by different methods of projection. In order in this case to construe the circles in II as representations of the figures in I, I shall have to give the method of projection for each circle; the mere fact that a figure in I is represented as a circle in II†1 by itself tells us nothing about the shape of the figure copied. That an image in II is a circle is just the established norm of our mapping.--Well, the same thing happens when we depict reality in our language in accordance with the subject-predicate form. The subject-predicate form serves as a projection of countless different logical forms.

Page 205

Frege's "Concept and Object" is the same as subject and predicate.

Page 205

If a table is painted brown, then it's easy to think of the wood as bearer of the property brown and you can imagine what remains the same when the colour changes. Even in the case of *one* particular circle which appears now red, now blue. It is thus easy to imagine *what* is red, but difficult to imagine what is circular. What *remains* in this case if form and colour alter? For position is part of the form and it is arbitrary for me to lay down that the centre should stay fixed and the only changes in form be changes in the radius.

Page 205

We must once more adhere to ordinary language and say that a *patch* is circular.

Page 205

It is clear that here the phrase "bearer of a property" in this context conveys a completely wrong--an impossible--picture. If I have a lump of clay, I can consider it as the bearer of a form, and that, roughly, is where this picture comes from.

Page Break 206

Page 206

"The patch changes its form" and "the lump of clay changes its form" are different forms of propositions.

Page 206

You can say "Measure whether *that* is a circle" or "See whether *that* over there is a hat". You can also say "Measure whether that is a circle or an ellipse", but not "... whether that is a circle or a hat"; nor "See whether that is a hat or red".

Page 206

If I point to a curve and say "That is a circle" then someone can object that if it were not a circle it would no longer be *that*. That is to say, what I mean by the word "that" must be independent of what I assert about it.

Page 206

("Was *that* thunder, or gunfire?" Here you could not ask "Was that a noise?")

Page 206

How are two circles of the same size distinguished? This question makes it sound as if they were pretty nearly one circle and only distinguished by a nicety.

Page 206

In the technique of representation by equations what is common is expressed by the form of the equation, and the difference by the difference in the coordinates of the centres.

Page 206

So it is as if what corresponds with the objects falling under the concept were here the coordinates of the centres.

Page 206

Couldn't you then say, instead of "This is a circle", "This point is the centre of a circle"? For to be the centre

of a circle is an external property of the point.

Page 206

What is necessary to a description that--say--a book is in a certain position? The internal description of the book, i.e. of the concept, and a description of its place which it would be possible to give by giving the co-ordinates of three points. The proposition "Such a book is *here*" would mean that it had *these* three co-ordinates. For the specification of the "here" must not prejudge *what* is here.

Page 206

But doesn't it come to the same thing whether I say "*This* is a book" or "Here is a book"? The proposition would then amount

Page Break 207

to saying, "These are three corners of such a book".

Page 207

Similarly you can also say "This circle is the projection of a sphere" or "This is a man's appearance".

Page 207

All that I am saying comes to this, that $\Phi(x)$ must be an *external* description of x .

Page 207

If in this sense I now say in three-dimensional space "Here is a circle" and on another occasion "Here is a sphere" are the two "here's" of the same type? I want to ask: can one significantly say of the same 'object': it is a circle, and: it is a sphere? Is the subject of each of these predicates of the same type? Both could be the three coordinates of the relevant centre-point. But the position of the circle in three-dimensional space is not fixed by the coordinates of its centre.

Page 207

On the other hand you can of course say "It's not the noise, but the colour that makes me nervous" and here it might look as if a variable assumed a colour and a noise as values. ("Sounds and colours can be used as vehicles of communication".) It is clear that this proposition is of the same kind as "if you hear a shot, or see me wave, run". For this is the kind of co-ordination on the basis of which a heard or seen language functions.

Page 207

"Is it conceivable that two things have all their properties in common?"--If it isn't conceivable, then neither is its opposite.

Page 207

We do indeed talk about a circle, its diameter, etc. etc., as if we were describing a concept in complete abstraction from the objects falling under it.--But in that case 'circle' is not a predicate in the original sense. And in general geometry is the place where concepts from the most different regions get mixed up together.

Page Break 208

3: *Objects*

Page 208

"In a certain sense, an object cannot be described." (So too Plato: "You can't give an account of one but only name it.") Here "object" means "reference of a not further definable word", and "description" or "explanation" really means: "definition". For of course it isn't denied that the object can be "described from outside", that properties can be ascribed to it and so on.

Page 208

So when we use the proposition above we are thinking of a calculus with signs or names that are indefinable--or, more accurately, undefined--and we are saying that no account can be given of them.

Page 208

"What a word means a proposition cannot tell."

Page 208

What is the distinction, then, between blue and red?

Page 208

We aren't of the opinion that one colour has one property and the other another. In any case, the properties of blue and red are that this body (or place) is blue, and that other is red.

Page 208

When asked "what is the distinction between blue and red?" we feel like answering: one is blue and the other red. But of course that means nothing and in reality what we're thinking of is the distinction between the surfaces or places that have these colours. For otherwise the question makes no sense at all.

Compare the different question: "What is the distinction between orange and pink?" One is a mixture of yellow and red, the other a mixture of white and red. And we may say accordingly: blue comes from purple when it gets more bluish, and red comes from purple when that gets more and more reddish.

So what I am saying means: red can't be described. But can't we represent it in painting by painting something red?

No, that isn't a representation in painting of the meaning of the word 'red' (there's no such thing).

The portrait of red.

Still, it's no accident that in order to define the meaning of the word "red" the natural thing is to point to a red object.

(What is natural about it is portrayed in that sentence by the double occurrence of the word 'red').

To say that blue is on the bluish side of blue-red and red on the reddish side is a grammatical sentence and therefore akin to a definition. And indeed one can also say: more bluish = more like blue.

"If you call the colour green an object, you must be saying that it is an object that occurs in the symbolism. Otherwise the sense of the symbolism, and thus its very existence as a symbolism, would not be guaranteed."

But what does that assert about green, or the word "green"? ((That sentence is connected with a particular conception of the meaning-relation and a particular formulation of the problem the relation raises)).

4:
Elementary Propositions
A†1

Can a logical product be hidden in a proposition? And if so, how does one tell, and what methods do we have of bringing the hidden element of a proposition to light? If we haven't yet got a method, then we can't speak of something being hidden or possibly hidden. And if we do have a method of discovery then the only way in which something like a logical product can be hidden in a proposition is the way in which a quotient like $753/3$ is hidden until the division has been carried out.

The question whether a logical product is hidden in a sentence is a mathematical problem.

So an elementary proposition is a proposition which, in the calculus as I am now using it, is not represented as a truth-function of other sentences.

The idea of constructing elementary propositions (as e.g. Carnap has tried to do) rests on a false notion of logical analysis. It is not the task of that analysis to discover a *theory* of elementary propositions, like discovering principles of mechanics.

My notion in the *Tractatus Logico-Philosophicus* was wrong: 1) because I wasn't clear about the sense of the words "a logical product is *hidden* in a sentence" (and suchlike), 2) because I too thought that logical analysis had to bring to light what was hidden (as chemical and physical analysis does).

The proposition "this place is now red" (or "this circle is now red") can be called an elementary proposition if this means that it is

neither a truth-function of other propositions nor defined as such. (Here I am disregarding combinations such as $p : q \vee \sim q$ and the like.)

Page 211

But from "a is now red" there follows "a is now not green" and so elementary propositions in this sense aren't independent of each other like the elementary propositions in the calculus I once described--a calculus to which, misled as I was by a false notion of reduction, I thought that the whole use of propositions must be reducible.

B†1

Page 211

If you want to use the appellation "elementary proposition" as I did in the *Tractatus Logico-Philosophicus*, and as Russell used "atomic proposition", you may call the sentence "Here there is a red rose" an elementary proposition. That is to say, it doesn't contain a truth-function and it isn't defined by an expression which contains one. But if we're to say that a proposition isn't an elementary proposition unless its complete logical analysis shows that it isn't built out of other propositions by truth-functions, we are presupposing that we have an idea of what such an 'analysis' would be. Formerly, I myself spoke of a 'complete analysis', and I used to believe that philosophy had to give a definitive dissection of propositions so as to set out clearly all their connections and remove all possibilities of misunderstanding. I spoke as if there was a calculus in which such a dissection would be possible. I vaguely had in mind something like the definition that Russell had given for the definite article, and I used to think that in a similar way one would be able to use visual impressions etc. to define the concept say of a sphere, and thus exhibit once for all the connections between the concepts and lay bare the source of all misunderstandings, etc. At the root of all this there was a false and idealized picture of the use of language. Of course, in particular cases one can

Page Break 212

clarify by definitions the connections between the different types of use of expressions. Such a definition may be useful in the case of the connection between 'visual impression' and 'sphere'. But for this purpose it is not a definition of the concept of a physical sphere that we need; instead we must describe a language game related to our own, or rather a whole series of related language games, and it will be in these that such definitions may occur. Such a contrast destroys grammatical prejudices and makes it possible for us to see the use of a word as it really is, instead of *inventing* the use for the word.

Page 212

There could perhaps be a calculus for dissecting propositions; it isn't hard to imagine one. Then it becomes a problem of calculation to discover whether a proposition is or is not an elementary proposition.

Page 212

The question whether e.g. a logical product is hidden in a sentence is a mathematical problem.--What "hidden" means here is defined by the method of discovery (or, as it might be, by the lack of a method).

Page 212

.....

What gives us the idea that there is a kind of agreement between thought and reality?--Instead of "agreement" here one might say with a clear conscience "pictorial character".†1

Page 212

But is this pictorial character an agreement? In the *Tractatus Logico-Philosophicus* I said something like: it is an agreement of form. But that is an error.

Page 212

First of all, "picture" here is ambiguous. One wants to say that an order is the picture of the action which was carried out on the order; but also, a picture of the action which *is to be* carried out as an order.

Page Break 213

Page 213

We may say: a blueprint *serves as a picture* of the object which the workman is to make from it.

Page 213

And here we might call the way in which the workman turns such a drawing into an artefact "the method of projection". We might now express ourselves thus: the method of projection mediates between the drawing and the object, it reaches from the drawing to the artefact. Here we are comparing the method of projection with projection lines which go from one figure to another.--But if the method of projection is a bridge, it is a bridge which isn't built until the application is made.--This comparison conceals the fact that the picture *plus* the projection lines leaves open

various methods of application; it makes it look as if what is depicted, even if it does not exist in fact, is determined by the picture and the projection lines in an ethereal manner; every bit as determined, that is to say, as if it did exist. (It is 'determined give or take a yes or no.'). In that case what we may call 'picture' is the blueprint plus the method of its application. And we now imagine the method as something which is attached to the blueprint whether or not it is used. (One can "*describe*" an application even if it doesn't exist).†1

Page 213

Now I would like to ask "How can the blueprint be used as a representation, unless there is already an agreement with what is to be made?"--But what does that mean? Well, perhaps this: how could I play the notes in the score on the piano if they didn't already have a relationship to particular types of movement of the hand? Of course such a relationship *sometimes* consists in a certain agreement, but sometimes not in any agreement, but merely in our having learnt to apply the signs in a particular way. What the comparison between the method of projection and the projection lines connecting the picture with the object does is to make all these cases alike--because *that* is what attracts us. You may say: I count the projection lines as part of the picture--but not the method of projection.

Page Break 214

Page 214

You may of course also say: I count a *description* of a method of projection as part of the picture.

Page 214

So I am imagining that the difference between proposition and reality is ironed out by the lines of projection belonging to the picture, the thought, and that no further room is left for a method of application, but only for agreement and disagreement.

Page Break 215

5:

*Is time essential to propositions?
Comparison between time and truth-functions*

Page 215

If we had grammar set out in the form of a book, it wouldn't be a series of chapters side by side, it would have quite a different structure. And it is here, if I am right, that we would have to see the distinction between phenomenological and non-phenomenological. There would be, say, a chapter about colours, setting out the rules for the use of colour-words; but there would be nothing comparable in what the grammar had to say about the words "not", "or", etc. (the "logical constants").

Page 215

It would, for instance, be a consequence of the rules, that these latter words unlike the colour words were usable in every proposition; and the generality belonging to this "every" would not be the kind that is discovered by experience, but the generality of a supreme rule of the game admitting of no appeal.

Page 215

How does the temporal character of facts manifest itself? How does it express itself, if not by certain expressions having to occur in our sentences? That means: how does the temporal character of facts express itself, if not grammatically? "Temporal character"--that doesn't mean that I come at 5 o'clock, but that I come at some time or other, i.e. that my proposition has the structure it has.

Page 215

We are inclined to say that negation and disjunction are connected with the nature of the proposition, but that time is connected with its content rather than with its nature.

Page 215

But if two things are equally universal, how can it show itself in grammar that one of them is connected with the nature of the proposition and the other is not?

Page 215

Or should I have said that time is not equally universal since mathematical propositions can be negated and occur in disjunctions, without being temporal? There is indeed a connection here, though this form of portraying the matter is misleading.

Page Break 216

Page 216

But that shows what I mean by "proposition." or "nature of the proposition".

Why--I want to ask--is the temporal character of propositions so universal?

Might one also put the question thus: "How does it happen that every fact of experience can be brought into a relationship with what is shown by a clock?"

Having two kinds of generality in the way I spoke of would be as strange as if there were two equally exceptionless rules of a game and one of them were pronounced to be more fundamental. As if one could ask whether in chess the king or the chess board was more important; which of the two was more essential, and which more accidental.

There's at least one question that seems in order: suppose I had written up the grammar, and the different chapters on the colour words, etc. etc. were there one after the other, like rules for each of the chess pieces, how would I know that those were *all* the chapters? If there turns out to be a common property in all the chapters so far in existence, we seem to have encountered a logical generality that is not an essential, i.e. *a priori* generality. But we can't say that the fact that chess is played with 16 pieces is any less essential to it than its being played on a chessboard.

Since time and the truth-functions taste so different, and since they manifest their nature only and wholly in grammar, it is grammar that must explain the different taste.

One tastes like content, the other like form of representation.

They taste as different as a plan and a line through a plan.

It appears to me that the present, as it occurs in the proposition "the sky is blue" (if this proposition isn't meant as a hypothesis), is not a form of time, so that the present in *this* sense is atemporal.

Does time enter into a landscape picture? or into a still life?

Literature consisting of descriptions of landscapes.

It is noteworthy that the time of which I am here speaking is not time in a physical sense. We are not concerned with measuring time. It is fishy that something which is unconnected with measurement is supposed to have a role in propositions like that of physical time in the hypotheses of physics.

Discuss:

The distinction between the logic of the content and the logic of the propositional form in general. The former seems, so to speak, brightly coloured, and the latter plain; the former seems to be concerned with what the picture represents, the latter to be a characteristic of the pictorial form like a frame.

By comparison with the way in which the truth-functions are applicable to all propositions, it seems to us accidental that all propositions contain time in some way or other.

The former seems to be connected with their nature as propositions, the latter with the nature of the reality we encounter.

((Added later in the margins))

A sentence can contain time in very different senses.

You are hurting me.

The weather is marvellous outside.

The Inn flows into the Danube.

Water freezes at 0°.

I often make slips of the pen

Some time ago...

I hope he will come.

At 5 o'clock.

Page Break 218

This kind of steel is excellent.
The earth was once a ball of gas.

Page Break 219

6:
The Nature of Hypotheses

Page 219

You could obviously explain an hypothesis by means of pictures. I mean, you could e.g. explain the hypothesis "there is a book lying here" with pictures showing the book in plan, elevation and various cross-sections.

Page 219

Such a representation gives a *law*. Just as the equation of a curve gives a law, by means of which you may discover the ordinates, if you cut at different abscissae.

Page 219

In which case the verifications of particular cases correspond to cuts that have actually been made.

Page 219

If our experiences yield points lying on a straight line, the proposition that these experiences are various views of a straight line is an hypothesis.

Page 219

The hypothesis is a way of representing this reality, for a new experience may tally with it or not, or possibly make it necessary to modify the hypothesis.

Page 219

If for instance we use a system of coordinates and the equation for a sphere to express the proposition that a sphere is located at a certain distance from our eyes, this description has a greater multiplicity than that of a verification by eye. The first multiplicity corresponds not to *one* verification but to a law obeyed by verifications.

Page 219

An hypothesis is a law for forming propositions.

Page 219

You could also say: an hypothesis is a law for forming expectations.

Page 219

A proposition is, so to speak, a particular cross-section of an hypothesis.

Page 219

According to my principle two suppositions must have the same sense if every *possible* experience that confirms the one also

Page Break 220

confirms the other, if, that is, no decision between the two is conceivable on the basis of experience.

Page 220

The representation of a curve as a straight line with deviations. The equation of the curve includes a parameter whose course expresses the deviations from a straight line. It isn't essential that these deviations should be "slight". They can be so large that the curve doesn't look like a straight line at all. "Straight line with deviations" is only one form of description. It makes it easier for me to eliminate, or neglect, a particular component of the description if I so wish. (The form "rule with exceptions").

Page 220

What does it mean, to be certain that one has toothache? (If one *can't* be certain, then grammar doesn't allow the use of the word "certain" in this connection.)

Page 220

The grammar of the expression "to be certain".

Page 220

We say "If I say that I see a chair there, I am saying more than I know for certain". And commonly that means "But all the same, there's *one* thing that I do know for certain." But if we now try to say what it is, we find ourselves in a certain embarrassment.

Page 220

"I see something *brown*--that is certain." That's meant to say that the brown colour is seen and not perhaps merely conjectured from other symptoms. And we do indeed say quite simply: "I *see* something brown."

If someone tells me "Look into this telescope, and make me a sketch of what you see", the sketch I make is the expression of a proposition, not of a hypothesis.

If I say "Here there is a chair", I mean more--people say--than the mere description of what I perceive. This can only mean that that proposition doesn't have to be true, even though the description fits what is seen. Well, in what circumstances would I say that that proposition wasn't true? Apparently, if certain other

propositions aren't true that were implicit in the first. But it isn't as if the first turns out to have been a logical product all along.

The best comparison for every hypothesis--something that is itself an example of an hypothesis--is a body in relation to a systematic series of views of it from different angles.

Making a discovery in a scientific investigation (say in experimental physics) is of course not the same thing as making a discovery in ordinary life outside the laboratory; but the two are *similar* and a comparison with the former can throw light on the latter.

There is an essential distinction between propositions like "That is a lion", "The sun is larger than the earth", and propositions like "Men have two hands". Propositions like the first pair contain a "this", "now", "here" and thus connect immediately with reality. But if there happened to be no men around, how would I go about checking the third proposition?

It is always single faces of hypotheses that are verified.

Perhaps this is how it is: what an hypothesis explains is itself only expressible by an hypothesis. Of course, this amounts to asking whether there are any primary propositions that are definitively verifiable and not merely facets of an hypothesis. (That is rather like asking: are there surfaces that aren't surfaces of bodies?)

At all events, there can't be any distinction between an hypothesis used as an expression of an immediate experience and a proposition in the stricter sense.

There is a distinction between a proposition like "Here there is a sphere in front of me" and "It looks as if there is a sphere in front of me". The same thing shows itself also thus: one can say "There seems to be a sphere in front of me", but it is senseless to say "It looks as if there seems to be a sphere here". So too one can say

"Here there is probably a sphere", but not "Here there probably appears to be a sphere". In such a case people would say "After all, you must know whether there *appears* to be".

There is nothing hypothetical in what connects the proposition with the given fact.

It's clear that reality--I mean immediate experience--will sometimes give an hypothesis the answer yes, and sometimes the answer no (here of course the "yes" and "no" express only confirmation and lack of confirmation); and it's clear that these affirmations and denials can be given expression.

The hypothesis, if *that* face of it is laid against reality, becomes a proposition.

It may be doubtful whether the body I see is a sphere, but it can't be doubtful that from here it looks to be something like a sphere.--The mechanism of hypothesis would not function if appearance too were doubtful so that one couldn't verify beyond doubt even a facet of the hypothesis. If there were a doubt here, what could take the doubt away? If this connection too were loose, there would be no such thing as confirming an hypothesis and it would hang entirely in the air, quite pointless (and therefore senseless).

If I say "I saw a chair", that (in *one* sense) isn't contradicted by the proposition "there wasn't one there". For I could use the first proposition in the description of a dream and then nobody would use the second to contradict me.

But the description of the dream throws a light on the sense of the words "*I saw*".

Page 222

Again, in the proposition "there wasn't one there", the word "there" may have more than one meaning.

Page Break 223

Page 223

I am in agreement with the opinions of contemporary physicists when they say that the signs in their equations no longer have any "meanings" and that physics cannot attain to any such meanings, but must stay put at the signs. But they don't see that the signs have meaning in as much as--and only in as much as--observable phenomena do or do not correspond to them, in however circuitous a manner.

Page 223

Let us imagine that chess had been invented not as a board game, but as a game to be played with numbers and letters on paper, so that no one had ever imagined a board with 64 squares in connection with it. And now suppose someone made the discovery that the game corresponded exactly to a game which could be played on a board in such and such a way. This discovery would have been a great simplification of the game (people who would earlier have found it too difficult could now play it). But it is clear that this new illustration of the rules of the game would be nothing more than a new, more easily surveyable symbolism, which in other respects would be on the same level as the written game. Compare with this the talk about physics nowadays not working with mechanical models but "only with symbols".

Page Break 224

7: *Probability*

Page 224

The probability of an hypothesis has its measure in how much evidence is needed to make it profitable to throw it out.

Page 224

It's only in this sense that we can say that repeated uniform experience in the past renders the continuation of this uniformity in the future probable.

Page 224

If, in this sense, I now say: I assume the sun will rise again tomorrow, because the opposite is so unlikely, I here mean by "likely" and "unlikely" something completely different from what I mean by these words in the proposition "It's equally likely that I'll throw heads or tails". The two meanings of the word "likely" are, to be sure, connected in certain ways, but they aren't identical.

Page 224

We only give up an hypothesis for an ever higher gain.

Page 224

Induction is a process based on a principle of economy.

Page 224

The question how simple a representation is yielded by assuming a particular hypothesis is directly connected, I believe, with the question of probability.

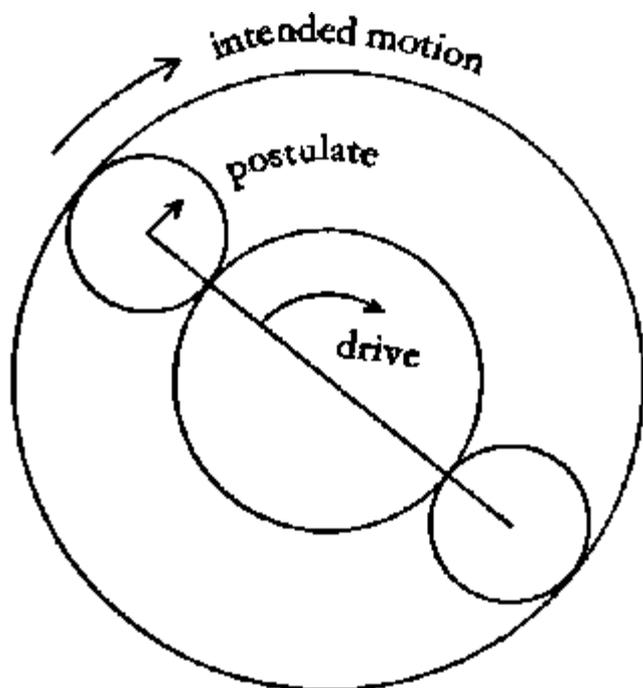

Page 224

We may compare a part of an hypothesis with the movement of a part of a gear, a movement that can be stipulated without prejudicing the intended motion. But then of course you have to make appropriate adjustments to the rest of the gear if it is to produce the desired motion. I'm thinking of a differential gear.--Once I've decided that there is to be no deviation from a certain part of my hypothesis no matter what the experience to be described may be, I have stipulated a mode of representation and this part of my hypothesis is now a postulate.

Page Break 225

Page 225

A postulate must be such that no conceivable experience can refute it, even though it may be extremely inconvenient to cling to the postulate. To the extent to which we can talk here of greater or slighter convenience, there is a greater or slighter probability of the postulate.

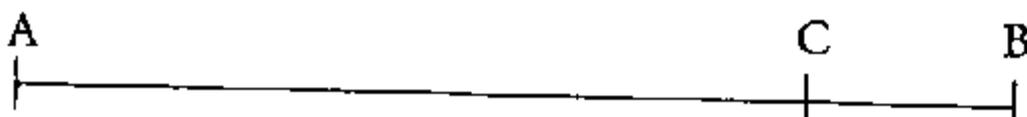

Page 225

It's senseless to talk of a measure for this probability at this juncture. The situation here is like that in the case of two kinds of numbers where we can with a certain justice say that the one is more like the other (is closer to it) than a third, but there isn't any numerical measure of the similarity. Of course you could imagine a measure being constructed in such cases, too, say by counting the postulates or axioms common to the two systems, etc. etc.

Page 225

I give someone the following piece of information, and no more: at such and such a time you will see a point of light appear in the interval AB.

Does the question now makes sense "Is it more likely that this point will appear in the interval AC than in CB"? I believe, obviously not.--I can of course decide that the probability of the event's happening in CB is to be in the ratio CB/AC to the

Page Break 226

probability of its happening in AC; however, that's a decision I can have empirical grounds for making, but about which there is nothing to be said *a priori*. It is possible for the observed distribution of events not to lead to this assumption. The probability, where infinitely many possibilities come into consideration, must of course be treated as a limit. That is, if I divide the stretch AB into arbitrarily many parts of arbitrary lengths and regard it as equally likely that the event should occur in any one of these parts, we immediately have the simple case of dice before us. And now I can--arbitrarily--lay down a law for constructing parts of equal likelihood. For instance, the law that, if the lengths of the parts are equal, they are equally likely. But any other law is just as permissible.

Page 226

Couldn't I, in the case of dice too, take, say, five faces together as one possibility, and oppose them to the sixth as the second possibility? And what, apart from experience, is there to prevent me from regarding these two possibilities as equally likely?

Page 226

Let's imagine throwing, say, a red ball with just one very small green patch on it. Isn't it much more likely in this case for the red area to strike the ground than for the green?--But how would we support this proposition? Presumably by showing that when we throw the ball, the red strikes the ground much more often than the green. But that's got nothing to do with logic.--We may always project the red and green surfaces and what befalls them onto a surface in such a way that the projection of the green surface is greater than or equal to the red; so that the events, as seen in this projection, appear to have a quite different probability ratio from the one they had on the original surface. If, e.g. I reflect the events

in a suitably curved mirror and now imagine what I would have held to be the more probable event if I had only seen the image in the mirror.

The one thing the mirror can't alter is the number of clearly demarcated possibilities. So that if I have *n* coloured patches on my ball, the mirror will also show *n*, and if I have *decided* that these are to be regarded as equally likely, then I can stick to this decision for the mirror image too.

To make myself even clearer: if I carry out the experiment with a concave mirror, i.e. make the *observations* in a concave mirror, it will perhaps then look as if the ball falls more often on the small surface than on the much larger one; and it's clear that neither experiment--in the mirror or outside it--has a claim to precedence.

We may apply our old principle to propositions expressing a probability and say, we shall discover their sense by considering what verifies them.

If I say "That will probably occur", is this proposition verified by the occurrence or falsified by its non-occurrence? In my opinion, obviously not. In that case it doesn't say anything about either. For if a dispute were to arise as to whether it is probable or not, it would always be arguments from the past that would be adduced. And this would be so even when what actually happened was already known.

Causality depends on an observed uniformity. This does not mean that a uniformity so far observed will always continue, but what cannot be altered is that the events so far have been uniform; *that* can't be the uncertain result of an empirical series which in its turn isn't something given but something dependent on another uncertain one and so on *ad infinitum*.

When people say that the proposition "it is probable that *p* will occur" says something about the event *p*, they forget that the probability remains even when the event *p* does *not* occur.

The proposition "*p* will probably occur" does indeed say something about the future, but not something "about the event *p*", as the grammatical form of the statement makes us believe.

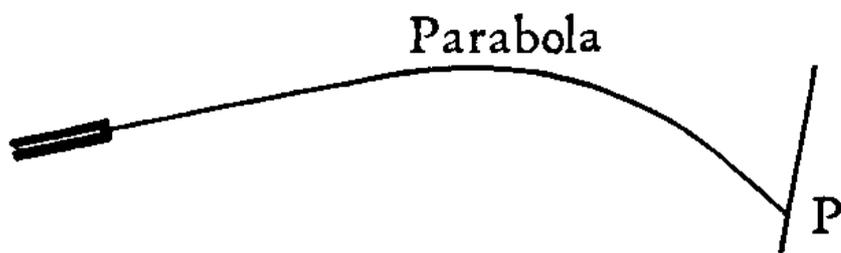

If I ask for the grounds of an assertion, the answer to the question holds not only for this person and for *this* action (assertion), but quite *generally*.

If I say "the weather looks like rain" do I say anything about future weather? No; I say something about the present weather, by means of a law connecting weather at any given time with weather at an earlier time. This law must already be in existence, and we are using it to construct certain statements about our experience.--

We might say the same of historical statements too. But I was too quick to say that the proposition "the weather looks like rain" says nothing about future weather. It all depends what is meant by "saying something about something". The sentence says just what it says.

The sentence "*p* will probably occur" says something about the future only in a sense in which its truth and falsehood are completely independent of what will happen in the future.

If we say: "the gun is now aiming at the point *p*" we aren't saying anything about where the shot will hit. Giving the point at which it is aiming is a *geometrical* means of assigning its direction. That this is the means we use is certainly connected with certain observations (projectile parabolas, etc.) but these observations don't enter into our present description of the direction.

Page Break 229

Page 229

A Galtonian photograph is the picture of a probability.

Page 229

The law of probability is the natural law you see when you screw up your eyes.

Page 229

"On average, the points yielded by the experiment lie on a straight line". "If I throw with a good die, then on average I throw a one every six throws". What does that mean? Is the proposition compatible with *any* experience I may have? If so, it says nothing. Have I decided in advance which experiences are incompatible with it and what is the limit beyond which exceptions may not go without upsetting the rule? No. But couldn't I have set such a limit? Of course.--Suppose that the limit had been set thus: if 4 out of 6 successive throws turn out the same, then it's a bad die. Now someone says: "But if that happens only very seldom, mayn't it be a good one after all?"--To that the answer is as follows. If I permit the turning up of 4 similar throws among 6 successive ones to occur within a certain number of throws, then I am replacing the first limit with a *different* one. But if I say "any number of similar successive throws is allowed, as long as it happens sufficiently rarely", then strictly speaking I've defined the goodness of the die in a way that makes it independent of the result of the throws; unless by the goodness of a die I do not mean a property of the die, but a property of a particular game played with it. In that case I can certainly say: in any game I call the die good provided that among the N throws of the game there occur not more than $\log N$ similar successive throws. However, that doesn't give a test for the checking of dice, but a criterion for judging a particular game.

Page 229

We say that if the die is quite regular and isn't interfered with then the distribution of the numbers 1, 2, 3, 4, 5, 6 among the throws must be uniform, since *there is no reason* why one number should occur more often than another.

Page Break 230

Page 230

But now let's represent the throws by the values of the function $(x - 3)^2$ for the arguments 1 to 6, i.e. by the numbers 0, 1, 4, 9 instead of by the numbers 1 to 6. Is there a reason why one of *these* numbers should turn up in the new results more often than another? This shows us that the *a priori* law of probability, like the minimum-principles of mechanics etc., is a form that laws may take. If it had been discovered by experiment that the distribution of the throws 1 to 6 with a regular die was such that the distribution of the values of $(x - 3)^2$ was uniform, it would have been *this* regularity that was defined as the *a priori* regularity.

Page 230

We do the same thing in the kinetic theory of gases: we represent the distribution of molecular movements in the form of some sort of uniform distribution; but we make the choice of *what* is uniformly distributed--and in the other case of *what* is reduced to a minimum--in such a way that our theory agrees with experience.

Page 230

"The molecules move purely according to the laws of probability" is supposed to mean: physics gets out of the way, and now the molecules move as it were purely according to laws of logic. This idea is similar to the idea that the law of inertia is an *a priori* proposition: there too one speaks of what a body does when it isn't interfered with. But what is the criterion for its not being interfered with? Is it ultimately that it moves uniformly in a straight line? Or is it something different? If the latter, then it's a matter of experience whether the law of inertia holds; if the former, then it wasn't a law at all but a definition. So too with the proposition, "if the particles aren't interfered with, then the distribution of their motions is such and such". What is the criterion for their not being interfered with? etc.

Page 230

To say that the points yielded in this experiment lie roughly on this line, e.g. a straight line, means something

like: "seen for this distance, they seem to lie on a straight line".

Page Break 231

Page 231

I may say that a stretch gives the general impression of a straight line; but I cannot say: "This bit of line looks straight, for it could be a bit of a line that as a whole gives me the impression of being straight." (Mountains on the earth and moon. The earth a ball.)

Page 231

An experiment with dice lasts a certain time, and our expectations about future throws can only be based on tendencies we observe in what happens during this experiment. That is to say, the experiment can only give grounds for expecting that things will go in *in the way* shown by the experiment; but we can't expect that the experiment, if continued, will now yield results that tally better with a preconceived idea of its course than did those of the experiment we have actually performed. So if, for instance, I toss a coin and find no tendency in the results of the experiment itself for the number of heads and tails to approximate to each other more closely, then the experiment gives me no reason to suppose that if it were continued such an approximation would emerge. Indeed, the expectation of such an approximation must *itself* refer to a definite point in time, since we can't say we're expecting something to happen *eventually*, in the infinite future.

Page 231

Any "reasonable expectation" is an expectation that a rule we have observed up to now will continue to hold.

Page 231

(But the rule must have been observed and can't, for its part too, be merely expected.)

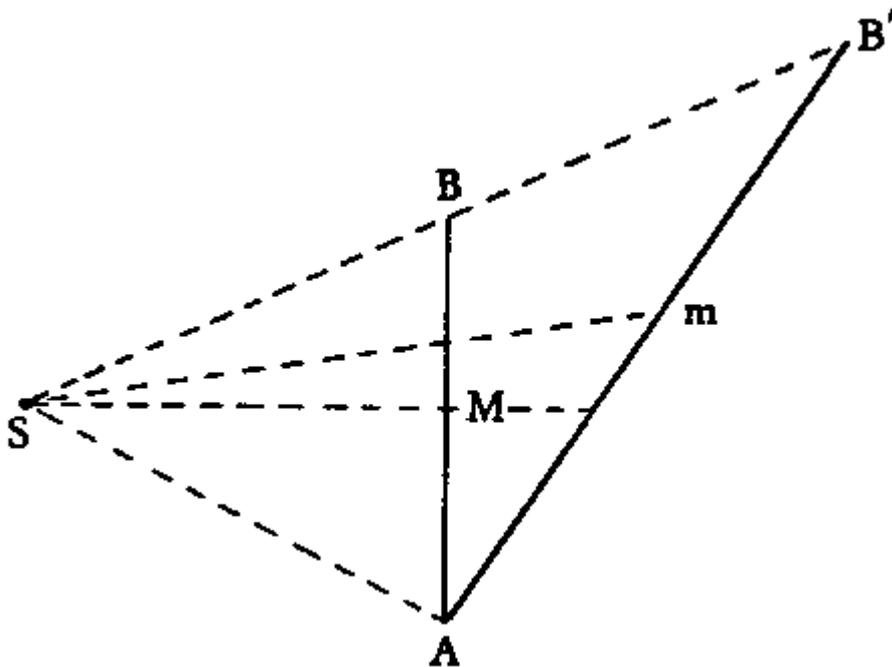

Page 231

The logic of probability is only concerned with the state of expectation in the sense in which logic in general is concerned with thinking.

Page 231

A ray is emitted from the light source S striking the surface AB to form a point of light there, and then striking the surface AB'. We have no reason to suppose that the point on AB lies to the left or to the right of M, and equally none for supposing that the

Page Break 232

point on AB' lies on one side or the other of m. This yields therefore incompatible probabilities. But if I make an assumption about the probability of the point on AB lying in AM, how is this assumption verified? Surely, we think, by a frequency experiment. Supposing this confirms the view that the probabilities of AM and BM are equal (and so the probabilities of Am and B'm differ), then it is recognized as the right one and thus shows itself to be an hypothesis belonging to physics. The geometrical construction merely shows that the fact that $AM = MB$ was *no* ground for assuming equal likelihood.

Page 232

Suppose that measurement shows the die to be accurate and regular, that the numbers on its sides don't influence the throws, and that it is thrown by a hand whose movements follow no definite rules: does it follow that

the distribution among the throws of each of the throws from 1 to 6 will be uniform on average? Where is the uniform distribution supposed to come from? The accuracy and regularity of the die can't establish that the distribution of throws will be *uniform on average*. (It would be, as it were, a monochrome premise with a mottle conclusion.) And we

Page Break 233

haven't made any suppositions about the movements while throwing. (Making the bundles of hay equal gives reason to believe that the donkey will starve to death between them; it doesn't give reason to believe that he will eat from each with roughly equal frequency.)--It is perfectly compatible with our assumptions for one hundred ones to be thrown in succession, if friction, hand-movements and air-resistance coincide appropriately. The experimental fact that this never happens is a fact about those factors, and the hypothesis that the throws will be uniformly distributed is an hypothesis about the operation of those factors.

Page 233

Suppose someone says that a lever with arms of equal length must remain at rest under the influence of equal and opposite forces, since there is no cause to make it move to one side rather than to the other. That only means that if the lever moves to one side after we have ascertained the equality of the arms and the equal and opposite nature of the forces, then we can't explain this on the basis of the preconditions we know or have assumed. (The form that we call "explanation" must be asymmetrical: like the operation which makes " $2a + 3b$ " out of " $a + b$ "). But on the basis of our presuppositions we can indeed explain the lever's continuance at rest.--Could we also explain a swing to left and right with roughly equal frequency? No, because once again the swing involves asymmetry; we would only explain the symmetry in this asymmetry. If the lever had rotated to the right with a uniform motion, one could similarly have said: given the symmetry of the conditions I can explain the uniformity of the motion, but not its direction.

Page 233

A lack of uniformity in the distribution of the throws is *not* to be explained by the symmetry of the die. It is only to this extent that the symmetry explains the uniformity of the distribution.--For one can of course say: if the numbers on the sides of the die have no effect, then the difference between them cannot explain an irregularity in the distribution; and of course similar circumstances can't explain differences; and so to that extent one might infer a regularity. But in that case why is there any difference at

Page Break 234

all between different throws? Whatever explains that must also explain their approximate regularity. It's just that the regularity of the die doesn't interfere with that regularity.

Page 234

Suppose that a man throwing dice every day threw nothing but ones for a week, using dice that proved good by every other method of testing and that gave the usual results when thrown by others. Has he grounds, now, for supposing that there is a law of nature that he will always throw ones? Has he grounds for believing that it will go on like this, or has he grounds for believing that this regularity can't last much longer? Has he reason to abandon the game since it has become clear that he can only throw ones, or reason to play on since in these circumstances it is all the more probable that he will throw a higher number at the next throw? In actual fact, he will refuse to accept the regularity as a natural law: at least, it will have to go on for a long time before he will entertain the possibility. But why? I believe it is because so much of his previous experience in life speaks against there being a law of nature of such a sort, and we have--so to speak--to surmount all that experience, before embracing a totally new way of looking at things.

Page 234

If we infer from the relative frequency of an event its relative frequency in the future, we can of course only do that from the frequency which has in fact been so far observed. And not from one we have derived from observation by some process or other for calculating probabilities. For the probability we calculate is compatible with *any* frequency *whatever* that we actually observe, since it leaves the time open.

Page 234

When a gambler or insurance company is guided by probability, they aren't guided by the probability calculus, since one can't be guided by this on its own, because *anything* that happens can be reconciled with it: no, the insurance company is guided by a

Page Break 235

frequency actually observed. And that, of course, is an absolute frequency.

The concept "about"
Problem of the "heap"

Page 236

"He came from about there →."

Page 236

"About *there* is the brightest point of the horizon".

Page 236

"Make the plank about 2 m long".

Page 236

In order to say this, must I know of limits which determine the margin of tolerance of this length? Obviously not. Isn't it enough e.g. to say "A margin of ± 1 cm is perfectly permissible; 2 would be too much"?--Indeed it's an essential part of the sense of my proposition that I'm not in a position to give "precise" bounds to the margin. Isn't that obviously because the space in which I am working here doesn't have the same metric as the Euclidean one?

Page 236

Suppose one wanted to fix the margin of tolerance exactly by experiment, by altering the length, approaching the limits of the margin and asking in each case whether such a length would do or not. After a few shortenings one would get contradictory results: at one time a point would be described as being within the limits, and at another time a point closer in would be described as impermissible, each time perhaps with the remark that the answers were no longer quite certain.

Page 236

It is the same sort of uncertainty as occurs in giving the highest point of a curve. We just aren't in Euclidean space and here there isn't a highest point in the Euclidean sense. The answer will mean "The highest point is about *there*" and the grammar of the word "about"--in this context--is part of the geometry of our space.

Page 236

Surely it is like the way the butcher weighs things only to the nearest ounce, though that is arbitrary and depends on what are the customary counterweights. Here it is enough to know: it doesn't weigh more than P_1 and it doesn't weigh less than P_2 . One might say: in principle giving the weight thus isn't giving a

Page Break 237

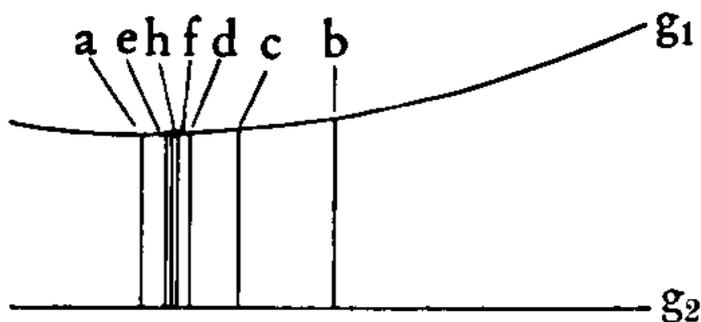

number, but an interval, and the intervals make up a discontinuous series.

Page 237

Yet one might say: "at all events keep *within* ± 1 cm", thus setting an arbitrary limit.--If someone now said "Right, but that isn't the real limit of the permissible tolerance; so what is?" the answer would be e.g. "I don't know of any; I only know that ± 2 is too much".

Page 237

Imagine the following psychological experiment.

The subject is shown curves g_1 g_2 with a straight line A drawn across them. I will call the section of this line between g_1 and g_2 a. Parallel to a we now draw b at an arbitrary distance and ask the subject whether he sees the section b as bigger than a, or cannot any longer distinguish between the two lengths. He replies that b seems bigger than a. Next we move closer to a, measuring half the distance from a to b and drawing c. "Do you see c as bigger than a?" "Yes."--We halve the distance c-a and draw d. "Do you see d as bigger than a?" "Yes." We halve a-d. "Do you see e as bigger than a?"--"No."--So we halve e-d. "Do you see f as bigger than e?"--"Yes."--So we halve e-f and draw h. We might approach the line a from the left hand side as well and then say that what corresponds in Euclidean space to a seen length a is not a single length but an interval of lengths, and in a similar way what corresponds to a single

seen position of a line (say the pointer of an instrument) is an interval of positions in Euclidean space; but this interval has no precise limits. That means: it is bounded not by

Page Break 238

points, but by converging intervals which do not converge upon a point. (Like the series of binary fractions that we get by throwing heads and tails.) The special thing about two intervals which are bounded in this *blurred* way instead of by points is that in certain cases the answer to the question whether they overlap or are quite distinct is "undecided"; and the question whether they touch, whether they have an end-point in common, is always a senseless one since they don't have end-points at all. But one might say "they have *de facto* end-points", in the sense in which the development of π has a *de facto* end. There is of course nothing mysterious about this property of "blurred" intervals; the somewhat paradoxical character is explained by the double use of the word "interval".

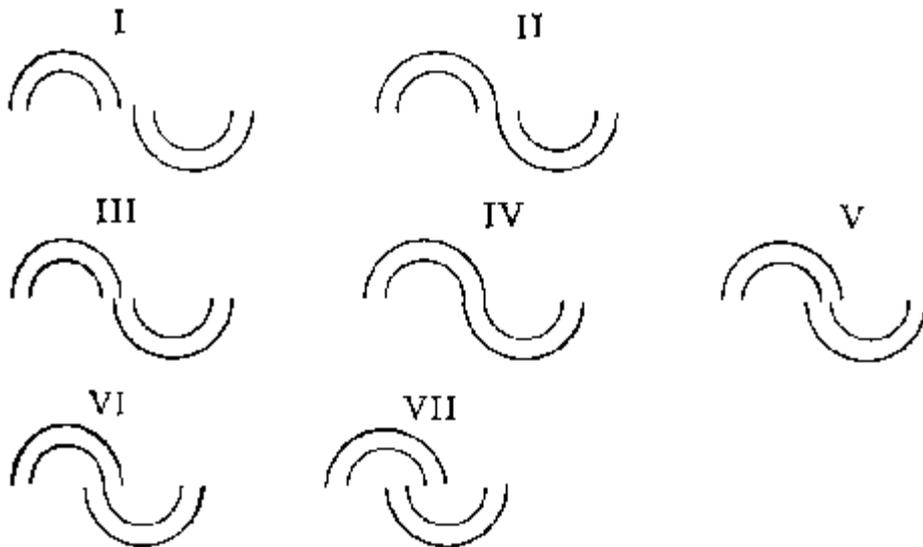

Page 238

The case is the same as that of the double use of the word "chess" to mean at one time the totality of the currently valid chess rules, and at another time the game invented in Persia by N. N. which developed in such and such a way. In one case it is nonsensical to talk of a development of the rules of chess and in another not. What we mean by "the length of a measured section" may be either what results from a particular measurement which I carry out today at 5 o'clock--in that case there is no " \pm etc." for this assignment of length--or, something to which measurements approximate, etc.; in the two cases the word "length" is used with quite different grammars. So too the word "interval" if what I mean by an interval is at one time something fixed and at another time something in flux.

Page 238

But we must not be surprised that an interval should have such a strange property; for we're now just using the word "interval" in a sense different from the usual one. And we can't say that we have discovered new properties of certain intervals, any more than we would discover new properties of the king in chess if we altered the rules of the game while keeping the designation "chess" and "king". (On the other hand cf. Brouwer on the law of excluded middle.)

Page Break 239

Page 239

- I) the intervals are separate
- II) they are separate with a *de facto* contact
- III) undecided
- IV) undecided
- V) undecided
- VI) they overlap
- VII) they overlap

Page 239

So basically that experiment gives what we have called a "blurred" interval; on the other hand of course we could conceive experiments which would give a sharp interval instead. Suppose we moved a straight-edge from the starting position b, in the direction of a, keeping it parallel to b, until our subject began to display a particular reaction; in that case we could call the point at which the reaction first occurs the limit of our strip. Likewise we

might of course call the result of a weighing "the weight of a body" and in that sense there would be an absolutely exact weighing, that is, one whose result did not have the form " $W \pm w$ ". We would thus have altered the form of our expression, and we would have to say that the weight of bodies varied according to a law that was unknown to us. (The distinction between "absolutely exact" weighing and "essentially inexact weighing" is a grammatical distinction connected with two different meanings of the expression "result of weighing").

Page Break 240

Page 240

The indeterminacy of the word "heap". I could give as a definition: a body of a certain form and consistency etc. is a heap, if it has a volume of K cubic metres, or more; anything less than that I will call a heaplet. In that case there is no largest heaplet; that means, it is senseless to speak of a largest heaplet. Conversely, I could decide: whatever is bigger than K cubic metres is to be a heap, and in that case the expression "the smallest heap" has no meaning. But isn't this distinction an idle one? Certainly--if by the volume we mean a result of measurement in the normal sense; for such a result has the form " $V \pm v$ ". But otherwise the distinction would be no more idle than the distinction between threescore apples and 61 apples.

Page 240

About the problem of the "heap": Here, as in similar cases, one might think that there is an official concept like the official length of a pace; say "A heap is anything that is bigger than half a cubic metre". But this would still not be the concept we normally use. For that there exists no delimitation (and if we fix one, we are altering the concept); it is just that there are cases that we count as within the extension of the concept, and cases that we no longer count as within the extension of the concept.

Page 240

"Make me a heap of sand here."--"Fine, that is certainly something he would call a heap." I was able to obey the command, so it was in order. But what about this command "Make me the smallest heap you would still call a heap"? I would say: that is nonsense; I can only determine a *de facto* upper and lower limit.

Page Break 241

Part II: On Logic and Mathematics

Page Break 242

Page Break 243

I LOGICAL INFERENCE

*Is it because we understand the propositions that we know that q entails p ?
Does a sense give rise to the entailment?*

Page 243

$p.q. = .p$ means " q follows from p ".

P	q	$p \vee q$	q	$(p \vee q).q$	$(p \vee q) \vee q$
T	T	T	T	T	T
T	F	T	F	F	T
F	T	T	T	T	T
F	F	F	F	F	F

Page 243

$(\exists x).fx \vee fa. = .(\exists x).fx, (\exists x).fx.fa. = .fa$. How do I know that? (Because for the equation above I gave a kind of proof). One might say something like: "I just understand ' $(\exists x).fx$ '". (An excellent example of what "understand" means).

But I might equally ask "How do I know that $(\exists x).fx$ follows from fa ?" and answer "because I understand ' $(\exists x).fx$ '."

But really how do I know that it follows?--Because that is the way I calculate.

How do I know that $(\exists x).fx$ follows from fa ? Is it that I as it were see behind the sign " $(\exists x).fx$ ", that I see the sense lying behind it and see from that that it follows from fa ? Is *that* what understanding is?

No, what that equation expresses is a part of the understanding (that is thus unpacked before my eyes).

Compare the idea that understanding is first of all grasping in a flash something which then has to be unpacked like that.

If I say "I know that $(\exists x).fx$ follows, because I understand it" that would mean, that when I understand it, I see something *different* from the sign I'm given, a kind of definition of the sign which gives rise to the entailment.

Isn't it rather that the connection is set up and prescribed by the equations? For there is no such thing as a hidden connection.

$(\exists x).fx$	fa
T	T
T	F
F	T
F	F

But, I used to think, mustn't $(\exists x).fx$ be a truth function of fa for that to be possible, for that connection to be possible?

For doesn't $(\exists x).Fx \vee Fa = (\exists x).fx$ simply say that fa is already contained in $(\exists x).fx$? Doesn't it show the connection between the fa and the $(\exists x).fx$? Not unless $(\exists x).fx$ is *defined* as a logical sum (with fa as one of the terms of the sum).--If that is the case, then $(\exists x).fx$ is merely an abbreviation.

In logic there is no such thing as a hidden connection.

You can't get behind the rules, because there isn't any behind.

$fE.fa. = fa$. Can one say: that is only possible if fE follows from fa ? Or must one say: that settles that fE is to follow from fa ?

If the former, it must be the structure that makes it follow, say because fE is so defined as to have the appropriate structure. But can the entailment really be a kind of result of the visible structure of the signs, in the way that a physical reaction is the result of a physical property? Doesn't it rather always depend on stipulations like the equation $fE.fa. = .fa$? Can it be read off from $p \vee q$ that

it follows from p , or only from the rules Russell gives for the truth-functions?

And why should the rule $fE.fa. = .fa$ be an effect of another rule rather than being itself the primary rule?

Page 245

For what is "fE must somehow contain fa" supposed to mean? It doesn't contain it, in so far as we can work with fE without mentioning fa; but it does in so far as the rule $fE.fa. = .fa$ holds.

Page 245

But the idea is that $fE.fa. = fa$ can only hold in virtue of a definition of fE.

Page 245

That is, I think, because otherwise it looks, wrongly, as if a further stipulation had been made about fE after it had already been introduced into the language. But in fact there isn't any stipulation left for future experience to make.

Page 245

And the definition of fE in terms of "all particular cases" is *no less* impossible than the enumeration of *all* rules of the form $fE.fx. = fx$.

Page 245

Indeed the individual equations $fE.fx. = fx$ are just precisely an expression of this impossibility.

Page 245

If we are asked: but is it now really certain that it isn't a different calculus being used, we can only say: if that means "don't we use other calculi too in our real language?" I can only answer "I don't know any others at present". (Similarly, if someone asked "are these all the calculi of contemporary mathematics?" I might say "I don't remember any others, but I can read it up and find out more exactly"). But the question cannot mean "can no other calculus be used?" For how is the answer to that question to be discovered?

Page 245

A calculus exists when one describes it.

Page Break 246

Page 246

Can one say 'calculus' is not a mathematical concept?

Page 246

If I were to say "whether p follows from q must result from p and q alone": it would have to mean this: that p follows from q is a stipulation that determines the sense of p and q, not some extra truth that can be asserted about the sense of both of them. Hence one can indeed give rules of inference, but in doing so one is giving for the use of the written signs rules which determine their as yet undetermined sense; and that means simply that the rules must be laid down arbitrarily, i.e. are not to be read off from reality like a description. For when I say that the rules are arbitrary, I mean that they are not determined by reality in the way the description of reality is. And that means: it is nonsense to say that they agree with reality, e.g. that the rules for the words "blue" and "red" agree with the facts about those colours etc.†1

Page 246

What the equation $p.q = p$ really shows is the connection between entailment and the truth-functions.

Page Break 247

2

"If p follows from q, then thinking that q must involve thinking that p."

Page 247

Remember that a general proposition might entail a logical sum of a hundred or so terms, which we certainly didn't think of when we uttered the general proposition. Yet can't we say that it follows from it?

Page 247

"What follows from a thought must be involved in thinking it. For there is nothing in a thought that we aren't aware of while we are thinking it. It isn't a machine which might be explored with unexpected results, a machine which might achieve something that couldn't be read off from it. That is, the way it works is *logical*, it's quite different from the way a machine works. *Qua* thought, it contains nothing more than was put into it. As a machine functioning causally, it might be believed capable of anything; but in logic we get out of it only what we meant by it."

Page 247

If I say that the square is entirely white, I don't think of ten smaller rectangles contained in it which are white, and I can't think of "*all*" rectangles or patches contained in it. Similarly in the proposition "he is in the room" I don't think of a hundred possible positions he might be in and certainly not of *all* possible positions.

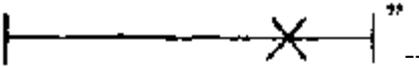

"Wherever you hit the target you've won. You've hit it in the upper right hand section, so... "

At first sight there seem to be two kinds of deduction: in one of them the premise mentions everything the conclusion does and in the other not. An instance of the first kind is the inference from $p \cdot q$ to q ; an instance of the second is the inference; the whole stick is white, so the middle third of it is white too. This conclusion mentions boundaries that are not mentioned in the first proposition. (That is dubious.) Again, if I say "If you hit the target anywhere in this circle you will win the prize..." and then "You have hit it here, so..." the place mentioned in the second proposition was not prescribed in the first. The target after the shot stands in a certain internal relation to the target as I saw it before, and that

relation consists in the shot's falling within the bounds of the general possibility that we foresaw. But the shot was not in itself foreseen and did not occur, or at least need not have occurred, in the first picture. For even supposing that at the time I thought of a thousand definite possibilities, it was at least possible for the one that was later realised to have been omitted. And if the foreseeing of that possibility really had been essential, the overlooking of this single case would have given the premise the wrong sense and the conclusion wouldn't any longer follow from it.

On the other hand you don't add anything to the proposition "Wherever you hit this circle..." by saying "Wherever you hit this circle, and in particular if you hit the black dot..." If the black dot was already there when the first proposition was uttered, then of course it was meant too; and if it wasn't there, then the actual sense of the proposition has been altered by it.

But what is it supposed to mean to say "If one proposition follows from another, thinking the second must involve thinking the first", since in the proposition "I am 170 cm tall" it isn't necessary to think of even a single one of the negative statements of height that follow from it?

"The cross is situated thus on the straight line: "

"So it is between the strokes".

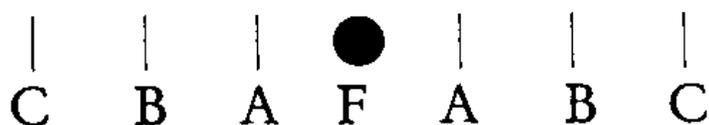

"It is $16\frac{1}{2}^\circ$ here"--"So it is certainly more than 15° "

Incidentally, if you are surprised that one proposition can follow from another even though one doesn't think of the former while thinking of the latter, you should consider that $p \vee q$ follows from p , and I certainly don't think all propositions of the form $p \vee \xi$ while I am thinking p .

The whole idea that a proposition has to be thought along with any proposition that entails it rests on a false, psychologising notion. We must concern ourselves only with what is contained in the signs and the rules.

If the criterion for p 's following from q consists in "thinking of p being involved in thinking of q " then while thinking of the proposition "in this box there are 10^5 grains of sand", you are thinking also of the 10^5 sentences "In this box there is one grain of sand" "... 2 grains of sand", etc. etc. What's the criterion here for the thought of one proposition's being involved in the thought of another?

And what about a proposition like "There is a patch (F) between the limits AA"?

Doesn't it follow from that that F is also between BB and CC and so on? Don't infinitely many propositions follow from a single one? Does that make it infinitely significant?--From the proposition "There is a patch between the limits AA " there follow as many propositions of the type "there is a patch between the limits BB " as I write

out--and no more than I write out. Similarly, from p there follow as many propositions of the form $p \vee \xi$ as I write out (or utter etc.).

Page 249

(A proof by induction proves as many propositions of the form... as I write out.)

Page Break 250

3

The case of infinitely many propositions following from a single one

Page 250

Is it impossible that infinitely many propositions should follow from a single one--in the sense, that is, that we might go on ad infinitum constructing new propositions from a single one according to a rule?

Page 250

Suppose that we wrote the first thousand propositions of the series in conjunction. Wouldn't the sense of this product necessarily approximate more closely to the sense of our first proposition than the product of the first hundred propositions? Wouldn't we obtain an ever closer approximation to the first proposition the further we extended the product? And wouldn't that show that it can't be the case that from one proposition infinitely many others follow, since I can't understand even the product with 10^{10} terms and yet I understood the proposition to which the product with 10^{100} terms is a closer approximation than the one with 10^{10} terms?

Page 250

We imagine, perhaps, that the general proposition is an abbreviated expression of the product. But what is there in the product to abbreviate? It doesn't contain anything superfluous.

Page 250

If we need an example of infinitely many propositions following from a single one, perhaps the simplest is the way in which "a is red" entails the negation of all propositions that ascribe a different colour to a. The negative propositions are certainly not contained in the thought of the single positive one. Of course we might say that we don't distinguish infinitely many shades of colour; but the question is whether the number of shades of colour we distinguish has anything at all to do with the complexity of the first sentence: is it more or less complex the more or fewer colours we distinguish?

Page 250

Wouldn't this be what we'd have to say: it's only when a proposition exists that it follows from it. It's only when we have constructed ten propositions following from the first one that ten propositions do follow from it.

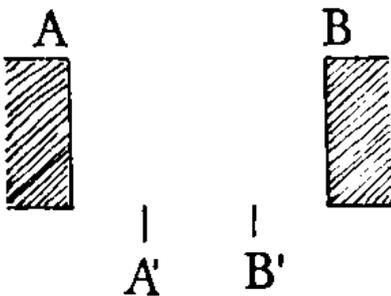

Page Break 251

Page 251

I want to say that one proposition doesn't follow from another until it is confronted with it. The "etc ad infinitum" indicates only the possibility [[sic]] of constructing propositions following from the first; it doesn't yield a definite number of such propositions.

Page 251

So mightn't I simply say: it is *because* it is impossible to write out infinitely many propositions (i.e. to say that is a piece of nonsense) that infinitely many propositions don't follow from a single proposition.

Page 251

What about the proposition "the surface is white from A to B"? It does follow from it that the surface is white from A' to B'. It needn't be a seen patch of white that is in question; and certainly the inference from the first proposition to the second is often drawn. Someone says to me "I have painted the patch white from A to B" and then I say "so it's certainly painted white from A' to B'".

Page 251

It must be possible to say a priori that $F(A'B')$ would follow from $F(AB)$.

If the lines A' and B' exist, then the second proposition certainly does follow from the first (in that case the compositeness is already there in the first proposition); but in that case it is only as many propositions as correspond to its compositeness that follow from the first proposition (and so never infinitely many).

"The whole is white, therefore a part bounded by such and such a line is white." "The whole *was* white, so that part of it also *was* white even if I didn't then perceive it bounded within it."

"A surface seen as undivided has no parts."

But let's imagine a ruler laid against the surface, so that the

appearance we are presented with is first  and then  and then

. It doesn't at all follow from the first strip's being entirely white that in the second and the third everything except the graduating lines is white.

"If you hit the target anywhere within the circle, you have won."

"I think you will hit the target somewhere within the circle."

Someone might ask about the first proposition: how do you know? Have you tried *all* possible places? And the answer would have to be: that isn't a proposition at all, it is a general *stipulation*.

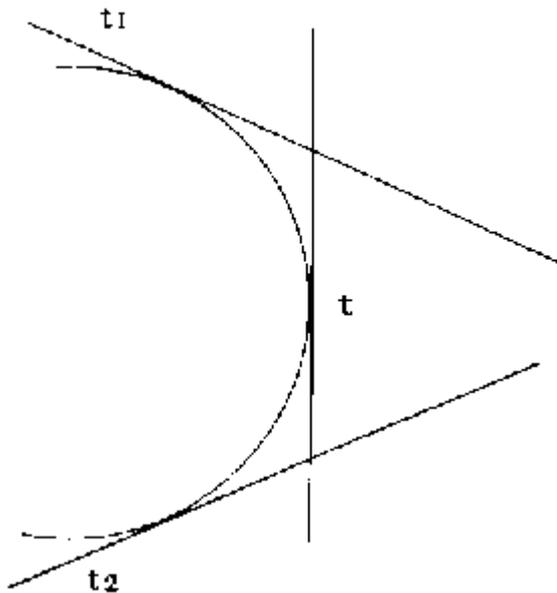

The inference doesn't go like this: "If the shot hits the target anywhere, you have won. You have hit the target *there*, so you have won". For where is this *there*? Is it marked out in any way other than by the shot--say by a circle? And was that already there on the target beforehand? If not, then the target has changed; if so, it must have been foreseen as a possible place to hit. We should rather say: "You have hit the target, so..."

The place on the target does not necessarily have to be given by a mark on the target, like a circle. For there are always descriptions like "nearer the centre", "nearer the edge", "on the right side at the top", etc. Wherever the target is hit such descriptions *must* always be possible. (But there are not "infinitely many" such descriptions.)

Does it make sense to say: "But if you hit the target, you must hit it *somewhere*" or "Wherever he hits the surface it won't be a surprise, we won't have to say 'I didn't expect that. I didn't know there was such a place?'" What that means is that it can't be a geometrical surprise.

What sort of proposition is: "On this strip you may see all shades of grey between black and white"? Here it looks at first glance as if we're talking about infinitely many shades.

Indeed, we are apparently confronted here by the paradox that we can, of course, only distinguish a finite number of shades, and naturally the distinction between them isn't infinitely slight, and yet we see a continuous transition.

Page 253

It is just as impossible to conceive of a particular grey as being one of the infinitely many greys between black and white as it is to conceive of a tangent t as being one of the infinitely many transitional stages in going from t_1 to t_2 . If I see a ruler roll around the circle from t_1 to t_2 I see--if its motion is continuous--none of the intermediate positions in the sense in which I see t when the tangent is at rest; or else I see only a finite number of such positions. But if in such a case I appear to infer a particular case from a general proposition, then the general proposition is never derived from experience, and the proposition isn't a real proposition.

Page 253

If, e.g., I say "I saw the ruler move from t_1 to t_2 *therefore* I must have seen it at t " this doesn't [[sic]] give us a valid logical inference. That is, if what I mean is that the ruler must have *appeared* to me at t and so, if I'm talking about the position in visual space, then it doesn't

Page Break 254

in the least follow from the premise. But if I'm talking about the physical ruler, then of course it's possible for the ruler to have skipped over position t and yet for the phenomenon in visual space to have remained continuous.

Page Break 255

4

Can an experience show that one proposition follows from another?

Page 255

The only essential point is that we cannot say that it was through experience we were made aware of an extra application of grammar. For in making that statement we would have to describe the application, and even if this is the first time I have realised that the description is true I must have been able to understand it even before the experience.

Page 255

It is the old question: how far can one now speak of an experience that one is not now having?

Page 255

What I cannot foresee I can not foresee.

Page 255

And what I can now speak of, I can now speak of independently of what I *can't* now speak of.

Page 255

Logic just is always complex.

Page 255

"How can I know everything that's going to follow?" What I can know then, I can also know now.

Page 255

But are there general rules of grammar, or only rules for general signs?

Page 255

What kind of thing in chess (or some other game) would count as a general rule or a particular rule? Every

rule is general.

Page 255

Still, there is one kind of generality in the rule that $p \vee q$ follows from p and a different kind in the rule that every proposition of the form $p, \sim\sim p, \sim\sim\sim p...$ follows from $p.q$. But isn't the generality of the rule for the knight's move different from the generality of the rule for the beginning of a game?

Page 255

Is the word "rule" altogether ambiguous? So should we talk only about particular cases of rules, and stop talking about rules in general, and indeed about languages in general?

Page 255

"If $F_1(a)$ [= a has the colour F_1] entails $\sim F_2(a)$ then the possibility of the second proposition must have been provided for in the

Page Break 256

grammar of the first (otherwise how could we call F_1 and F_2 colours?)

Page 256

"If the second proposition as it were turned up without being expected by the first it couldn't possibly follow from it."

Page 256

"The first proposition must acknowledge the second as its consequence. Or rather they must be united in a single grammar which remains the same before and after the inference."

Page 256

(Here it is very difficult not to tell fairy tales about symbolic processes, just as elsewhere it is hard not to tell fairy tales about psychological processes. But everything is simple and familiar (there is nothing new to be discovered). That is the terrible thing about logic, that its extraordinary difficulty lies in the fact that nothing must be constructed, and everything is already present familiar.)

Page 256

"No proposition is a consequence of p unless p acknowledges it as its consequence."

Page 256

Whether a proposition entails another proposition must be clear from the grammar of the proposition and from that alone. It cannot be the result of any insight into a new sense: only of an insight into the old sense. It is not possible to construct a new proposition that follows from the old one which could not have been constructed (perhaps without knowing whether it was true or false) when the old one was constructed. If a new sense were discovered and followed from the first proposition, wouldn't that mean that that proposition had altered its sense?

Page Break 257

II GENERALITY

The proposition "The circle is in the square" is in a certain sense independent of the assignment of a particular position. (In a certain sense it is totally unconnected.)

Page 257

I would like to say: a general picture like $|0|$ does not have the same metric as a particular one.

Page 257

In the general sign " $|0|$ " the distances play no greater part than they do in the sign " aRb ".

Page 257

The drawing $|0|$ can be looked on as a representation of the "general case". It is as if it were not in a measurable space: the distances between the circle and the lines are of no consequence. The picture, taken thus, is not seen as occurring in the same system as when one sees it as the representation of a particular position of the circle between the lines. Or rather, taken thus, it is a part of a different calculus. The rules that govern variables are not the same as those that govern their particular values.

Page 257

"How do you know he is in the room?" "Because I put him in and there is no way he can get out." Then your knowledge of the general fact that he is somewhere in the room has the same multiplicity as that reason.

Page 257

Let us take the particular case of the general state of affairs of the cross being between the end-lines.

Each of these cases, for instance, has its own individuality. Is there any way in which this individuality enters into the sense of the general sentence? Obviously not.

'Being between the lines, or the walls' seems something simple and the particular positions (both the visual appearances and the

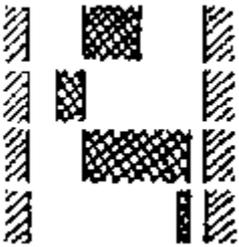

positions established by measurement) seem quite independent of it.

That is, when we talk about the individual (seen) positions we appear to be talking about something quite different from the topic of the general proposition.

There is one calculus containing our general characterization and another containing the disjunction. If we say that the cross is between the lines we don't have any disjunction ready to take the place of the general proposition.

If we consider a general proposition like "the circle is in the square" it appears time and again that the assignment of a position in the square is not (at least so far as visual space is concerned) a more precise specification of the statement that the circle is *in the square* any more than a statement of the colour of a material is a more precise specification of a statement of its hardness.--Rather, "in the square" appears a complete specification which in itself does not admit of any more precise description. Now of course the statements about the circle are not related to each other like the statements about colour and hardness, and yet that feeling is not baseless.

The grammatical rules for the terms of the general proposition must contain the multiplicity of possible particular cases provided for by the proposition. What isn't contained in the rules isn't provided for.

All these patterns might be the same state of affairs distorted. (Imagine the two white strips and the middle black strip as elastic.)

Does fa's following from (x). fx mean that a is mentioned in

(x). fx? Yes, if the general proposition is meant in such a way that its verification consists in an enumeration.

If I say "there is a black circle in the square", it always seems to me that here again I have something simple in mind, and don't have to think of different possible positions or sizes of the circle. And yet one may say: if there is a circle in the square, it must be somewhere and have some size. But in any case there cannot be any question of my thinking in advance of *all* the possible positions and sizes.--It is rather that in the first proposition I seem to put them through a kind of sieve so that "circle in a square" corresponds to a single impression, which doesn't take any account of the *where* etc., as if it were (against all appearance) something only physically, and not logically, connected with the first state of affairs.

The point of the expression "sieve" is this. If I look at a landscape or something similar through a glass which transmits only the distinction between brightness and darkness and not the distinctions between colours, such a glass can be called a sieve; and if one thinks of the square as being looked at through a glass which transmits only the distinction "circle in the square or not in the square" and no distinction between positions or sizes of the circle, here too we might speak of a sieve.

I would like to say that in the proposition "there is a circle in the square" the particular positions are not mentioned at all. In the picture I don't see the position, I disregard it, as if the distances from the sides of the square were elastic and their lengths of no account.

Page 259

Indeed, can't the patch actually be moving in the square? Isn't that just a special case of being in the square? So in that case it wouldn't be true that the patch has to be in a particular position in the square if it is there at all.

Page 259

I want to say that the patch seems to have a relation to the edge that is independent of its distance.--Almost as if I were using a

Page Break 260

geometry in which there is no such thing as distance, but only inside and outside. Looked at in this way, there is no

doubt that the two pictures are the same.

Page 260

By *itself* the proposition "The patch is in the square" does no more than hold the patch in the square, as it were; it is only in this way that it limits the patch's freedom; within the square it allows it complete freedom. The proposition constructs a frame that limits the freedom of the patch but within the frame it leaves it free, that is, it *has nothing to do* with its position. For that to be so the proposition must have the logical nature of the frame (like a box enclosing the patch). And so it has, because I could explain the proposition to someone and set out the possibilities, quite independently of whether such a proposition is true or not, independently of a fact.

Page 260

"Wherever the patch is in the square..." means "as long as it is in the square..." and here all that is meant is the freedom (lack of restraint) in the square, not a set of positions.

Page 260

Of course between this freedom and the totality of possibilities, there is a logical similarity (formal analogy), and that is why the same words are often used in the two cases ("all", "every", etc.).

Page 260

"No degrees of brightness below this one hurt my eyes." Test the type of generality.

Page 260

"All points on this surface are white." How do you verify that?--then I will know what it means.

Page Break 261

6

The proposition "The circle is in the square" is not a disjunction of cases.

Page 261

If I say the patch is in the square, I know--and must know--that it may have various possible positions. I know too that I couldn't give a definite number of all such positions. I do not know in advance how many positions "I could distinguish".--And trying it out won't tell me what I want to know here either.

Page 261

The darkness veiling the possible positions etc. is the current logical situation, just as dim lighting is a particular sort of lighting.

Page 261

Here it always seems as if we can't quite get an overall view of a logical form because we don't know how many or what possible positions there are for the patch in the square. But on the other hand we do know, because we aren't surprised by any of them when they turn up.

Page 261

Of course "position of the circle in this square" isn't a concept which particular positions fall under as objects. You couldn't discover objects and ascertain that they were positions of the circle in the square which you didn't know about beforehand.

Page 261

Incidentally, the centre and other special positions in the circle are quite analogous to the primary colours on the colour scale. (This comparison might be pursued with profit.)

Page 261

Space is as it were a single possibility; it doesn't consist of several possibilities.

Page 261

So if I hear that the book is somewhere on the table, and then find it in a particular position, it isn't possible for me to be surprised and say "oh, I didn't know that there was this position"; and yet I hadn't foreseen this particular position i.e. envisaged it in

Page Break 262

advance a particular possibility. It is physical, not logical possibilities that take me by surprise!

Page 262

But what is the difference between "the book is somewhere on the table" and "the event will occur sometime in the future?" Obviously the difference is that in the one case we have a sure method of verifying whether the book is on the table, while in the other case there is no such method. If a particular event were supposed to occur at one of the infinitely many bisections of a line, or better, if it were supposed to occur when we cut the line at a single point, not further specified, and then waited a minute at that point, that statement would be as senseless as the one about the infinite future.

Page 262

Suppose I stated a disjunction of so many positions that it was impossible for me to see a single position as distinct from all those given; would *that* disjunction be the general proposition $(\exists x).fx$? Wouldn't it be a kind of pedantry to continue to refuse to recognize the disjunction as the general proposition? Or is there an essential distinction, and is the disjunction totally unlike the general proposition?

Page 262

What so strikes us is that the one proposition is so complicated and the other so simple. Or is the simple one only an abbreviation for the more complicated one?

Page 262

What then is the criterion for the general proposition, for the circle's being in the square? Either, nothing that has anything to do with a set of positions (or sizes) or something that deals with a finite number of such positions.

Page 262

If one says that the patch A is somewhere between the limits B and C, isn't it obviously possible to describe or portray a number of positions of A between B and C in such a way that I see the succession of all the positions as a continuous transition? And in

Page Break 263

that case isn't the disjunction of all those N positions the very proposition that A is somewhere between B and C?

Page 263

But what are these N pictures really like? It is clear that a picture must not be visually discernible from its immediate successor, or the transition will be discontinuous.

Page 263

The positions whose succession I see as a continuous transition are positions which are not in visual space.

Page 263

How is the extension of the concept "lying between" determined? Because it has to be laid down in advance what possibilities belong to this concept. As I say, it cannot be a surprise that I call *that* too "lying between". Or: how can the rules for the expression "lie between" be given when I can't enumerate the cases of lying between? Of course that itself must be a characteristic of the meaning of the expression.

Page 263

Indeed if we wanted to explain the word to someone we wouldn't try to do so by indicating *all particular instances*, but by showing him one or two such instances and intimating in some way that it wasn't a question of the particular case.

Page 263

It is not only that the enumeration of positions is unnecessary: in the nature of things there can be no question of such an enumeration here.

Page 263

Saying "The circle is either between the two lines or *here*" (where "here" is a place between the lines) obviously means no more than "The circle is between the two lines", and the rider "or here" is superfluous. You will say: the "here" is already included in the "somewhere". But that is strange, since it isn't mentioned in it.

Page 263

There is a particular difficulty when the signs don't appear to say what the thought grasps, or the words don't say what the thought appears to grasp.

Page Break 264

As when we say "this theorem holds of all numbers" and think that in our thought we have comprehended all numbers like apples in a box.

But now it might be asked: how can I know in advance which propositions entail this general proposition, if I can't specify the propositions?

But can one say "We can't say which propositions entail this proposition"? That sounds like: we don't know. But of course that isn't how it is. I can indeed say, and say in advance, propositions that entail it. "Only not *all* of them." But that just has no meaning.

There is just the general proposition and particular propositions (not *the* particular propositions). But the general proposition does not enumerate particular propositions. In that case what characterizes it as general, and what shows that it doesn't simply comprise the particular propositions we are speaking of in this particular case?

It cannot be characterized by its instantiations, because however many we enumerate, it could still be mistaken for the product of the cited cases. Its generality, therefore, lies in a property (a grammatical property) of the variables.

The inadequacy of the Frege-Russell notation for generality

The real difficulty lies in the concept of " $(\exists n)$ " and in general of " $(\exists x)$ ". The original source of this notation is the expression of our word-language: "There is a... with such and such properties". And here what replaces the dots is something like "book from my library" or "thing (body) in this room", "word in this letter", etc. We think of objects that we can go through one after the other. As so often happens a process of sublimation turned this form into "there is an object such that..." and here too people imagined originally the objects of the world as like 'objects' in the room (the tables, chairs, books, etc.), although it is clear that in many cases the grammar of this " $(\exists x)$, etc." is not at all the same as the grammar of the primitive case which serves as a paradigm. The discrepancy between the original picture and the one to which the notation is now applied becomes particularly palpable when a proposition like "there are two circles in this square" is rendered as "there is no object that has the property of being a circle in this square without being the circle a or the circle b" or "there are not three objects that have the property of being a circle in this square". The proposition "there are only two things that are circles in this square" (construed on the model of the proposition "there are only two men who have climbed this mountain") sounds crazy, with good reason. That is to say, nothing is gained by forcing the proposition "there are two circles in this square" into that form; it only helps to conceal that we haven't cleared up the grammar of the proposition. But at the same time the Russellian notation here gives an appearance of exactitude which makes people believe the problems are solved by putting the proposition into the Russellian form. (This is no less dangerous than using the word "probably" without further investigation into the use of the word in this particular case. For understandable reasons the word

"probably", too, is connected with an idea of exactitude.)

"One of the four legs of this table doesn't hold", "There are Englishmen with black hair", "There is a speck on this wall" "The two pots have the same weight", "There are the same number of words on each of the two pages". In all these cases in the Russellian notation the " $(\exists \dots)$..." is used, and each time with a different grammar. The point I want to make is that nothing much is gained by translating such a sentence from word-language into Russellian notation.

It makes sense to say "write down any cardinal number" but not "write down all cardinal numbers". "There is a circle in the square" $(\exists x).fx$ makes sense, but not $\sim \exists x.\sim fx$: "all circles are in the square." "There is a red circle on a background of a different colour" makes sense, but not "there isn't a background-colour other than red that doesn't have a red circle on it."

"In this square there is a black circle". If this proposition has the form " $(\exists x).x$ is a black circle in a square" what sort of thing is it that has the property of being a black circle (and so can also have the property of not being a

black circle)? Is it a place in the square? But then there is no proposition "(x).x is a black..." On the other hand the proposition could mean "There is a speck in the square that is a black circle". How is that proposition verified? Well, we take the different specks in the square in turn and investigate whether they are quite black and circular. But what kind of proposition is "There isn't a speck in the square"? For if in the former case the 'x' in '(∃x)' meant 'speck in the square', then though "(∃x).fx" is a possible proposition both "(∃x)" and "¬(∃x)" are not. Or again, I might ask: what sort of thing is it that has (or does not have) the property of being a speck in the square?

Page 266

And if we can say "There is a speck in the square" does it then also make sense to say "All specks are in the square"? All *which*?

Page Break 267

Page 267

Ordinary language says "In this square there is a red circle"; the Russellian notation says "There is an object which is a red circle in this square". That form of expression is obviously modelled on "There is a substance which shines in the dark" "There is a circle in this square which is red".--Perhaps even the expression "there is" is misleading. "There is" really means the same as "Among these circles there is one..." or "... there exists one...".

Page 267

So if we go as far as we can in the direction of the Russellian mode of expression and say "In this square there is a place where there is a red circle", that really means, among these places there is one where... etc.

Page 267

(In logic the most difficult standpoint is that of sound common sense. For in order to justify its view it demands the whole truth; it will not help by the slightest concession or construction.)

Page 267

The correct expression of this sort of generality is therefore the expression of ordinary language "There is a circle in the square", which simply leaves the position of the circle *open* (leaves it *undecided*). ("Undecided" is a correct expression, since there just *has not been* any decision.)

Page Break 268

8

Criticism of my former view of generality

Page 268

My view about general propositions was that $(\exists x).\phi x$ is a logical sum and that though its terms aren't enumerated *here*, they are capable of being enumerated (from the dictionary and the grammar of language).

Page 268

For if they can't be enumerated we don't have a logical sum. (A rule, perhaps, for the construction of logical sums).

Page 268

Of course, the explanation of $(\exists x).\phi x$ as a logical sum and of $(x).\phi x$ as a logical product is indefensible. It went with an incorrect notion of logical analysis in that I thought that some day the logical product for a particular $(x).\phi x$ would be found.--Of course it is correct that $(\exists x).\phi x$ behaves in some ways like a logical sum and $(x).\phi x$ like a product; indeed for *one* use of words "all" and "some" my old explanation is correct,--for instance for "all the primary colours occur in this picture" or "all the notes of the C major scale occur in this theme". But for cases like "all men die before they are 200 years old" my explanation is not correct. The way in which $(\exists x).\phi x$ behaves like a logical sum is expressed by its following from ϕa and from $\phi a \vee \phi b$, i.e. in the rules

$$\begin{aligned} (\exists x).\phi x:\phi a. &= .\phi a & \text{and} \\ (\exists x).\phi x:\phi a \vee \phi b. &= .\phi a \vee \phi b \end{aligned}$$

Page 268

From these rules Russell's fundamental laws follow as tautologies:

$$\begin{aligned} \phi x.\supset.(\exists z).\phi z \\ \phi x \vee \phi y.\supset.(\exists z).\phi z \end{aligned}$$

Page 268

For $(\exists x).\phi x$ we need also the rules:

$$(\exists x).\phi x \vee \psi x. = .(\exists x).\phi x.\vee.(\exists x).\psi x$$

$(\exists x,y)\phi x.\psi y.\vee.(\exists x).\phi x.\psi x. = .(\exists x).\phi x:(\exists x).\psi x.$

Page 268

Every such rule is an expression of the analogy between $(\exists x).\phi x$ and a logical sum.

Page Break 269

Page 269

Incidentally, we really could introduce a notation for $(\exists x).\phi x$ in which it was replaced by a sign " $\phi r \vee \phi s \vee \phi t...$ " which could then be used in calculation like a logical sum; but we would have to provide rules for reconverting this notation at any time into the " $(\exists x).\phi x$ " notation and thus distinguishing the sign " $\phi a \vee \phi b \vee \phi c...$ " from the sign for a logical sum. The point of this notation could simply be to enable us to calculate more easily with $(\exists x).\phi x$ in certain cases.

Page 269

If I am right, there is no concept "pure colour"; the proposition "A's colour is a pure colour" simply means "A is red, or yellow, or blue, or green". "This hat belongs either to A or B or C" is not the same proposition as "This hat belongs to a person in this room" even when in fact only A, B and C are in the room, for that itself is something that has to be added.--"On this surface there are two pure colours" *means*: on this surface there is red and yellow, or red and green, or... etc.

Page 269

If this means I can't say "there are 4 pure colours", still the pure colours and the number 4 are somehow connected with each other and that must express itself in some way.--For instance, I may say "on this surface I see 4 colours: yellow, blue, red, green".

Page 269

The generality notation of our ordinary language grasps the logical form even more superficially than I earlier believed. In this respect it is comparable with the subject-predicate form.

Page 269

Generality is as ambiguous as the subject-predicate form.

Page 269

There are as many different "alls" as there are different "ones".

Page 269

So it is no use using the word "all" for clarification unless we know its grammar in this particular case.

Page Break 270

9

The explanation of generality by examples

Page 270

Let us think how we explain the concept plant. We show someone several objects and say they are plants; then he points to another object and asks "is that a plant too?" and we reply "yes, that too" etc. I would once have said that he has now seen in what he has been shown the concept 'plant'--the common element--and that he does not see the examples used in the explanation in the same way when he sees the concept in them as when he views them just as representatives of a particular shape and colour or the like. (Just as I also used to say that when he understands variables as variables he sees something in them which he doesn't see in the sign for the particular case). But the notion of "seeing in" is taken from the case in which I see a figure like |||| differently "phrased". In that case, I really do see different figures, but in a different sense; and what these have in common, apart from their similarity, is their being caused by the same physical pattern.

Page 270

But this explanation cannot be applied without further ado to the case of the understanding of a variable or of the examples illustrating the concept "plant". For suppose we really had seen something in them that we don't see in plants that are shown only for their own sake, the question remains whether this, or any other, picture can entitle us to apply them as variables. I might have shown someone the plants by way of explanation and given him in addition a drug causing him to see the examples in the special way. (Just as it would be possible that a drunken man might always see a group like |||| as ||| |). And this would give the explanation of the concept in an unambiguous manner, and the specimens exhibited and the accompanying gestures would communicate to anyone who understood just *this* picture. But that is not the way it is.--It may well be true that someone who sees a sign like ||||| as a numeral for 6 sees it differently (sees something different in it) from someone who views it only as a

Page Break 271

sign for "some", since he fixes his attention on something different; but what matters is the system of rules

governing the signs, and it isn't seeing the signs in a particular manner that is the essence of understanding.

Page 271

It would be possible to say "now I don't see it as a rose, but as a plant".

Page 271

Or "now I see it only as a rose, and no longer as *this* rose".

Page 271

"I see the patch merely in the square and no longer in a specific position."

Page 271

The mental process of understanding is of no interest to us (any more than the mental process of an intuition).

Page 271

"Still, there's no doubt that someone who understands the examples as arbitrary cases chosen to illustrate the concept doesn't understand the same as a man who regards them as a definitely bounded enumeration." Quite right, but *what* does the first man understand that the second doesn't? Well, in the things he is shown he sees only *examples* to illustrate certain features; he doesn't think that I am showing him the things for their own sake as well.--

Page 271

I would like to call the one class "logically bounded" and the other "logically unbounded".

Page 271

Yes, but is it really true that he sees only these features in the things? In a leaf, say, does he see only what is common to all leaves? That would be as if he saw everything else blank like an uncompleted form with the essential features ready printed. (But the function "f(...)" is just such a form.)

Page 271

But what sort of a process is it when someone shows me several different things as examples of a concept to get me to see what is common to them, and when I look for it and then actually see it? He may *draw my attention* to what is common.--But by doing this

Page Break 272

does he make me *see* the object differently? Perhaps so; for surely I may take a special look at one of the parts, when otherwise I would have seen the whole with equal clarity. But this seeing is not the understanding of the concept. For what we see isn't something with an *empty* argument place.

Page 272

One might also ask: Does a man who regards the sign "|||..." as a sign for the concept of number (in contrast with "|||" to denote 3) see the first group of lines differently from the second? Even if he does see it differently (perhaps, as it were, more blurred) does he *see* there anything like the essence of the concept of number? Wouldn't that mean that he would actually have to be unable to distinguish "|||..." and "||||..." from each other? (As indeed he would, if I had given him some drug that made him see the *concept*.)

Page 272

For if I say: by giving us a few examples he makes us see the common element in them and disregard the rest, that really means that the rest falls into the background, as it were becomes paler (or altogether disappears--why not?) and "the common element", say the oval shape, remains alone in the foreground.

Page 272

But that isn't the way it is. Apart from anything else, the multiplicity of examples would be no more than a mechanical device, and once I had seen what I was supposed to, I could see it in a single example too. (As indeed '($\exists x$).fx' itself contains only *one* example.)

Page 272

So it is the rules governing the example that make it an example.

Page 272

But by now at any rate, if someone says to me something like "make an egg shape" the bare concept word without any illustration suffices to make itself understood (and the past history of this understanding is of no interest to us); and I do not want to say that when I understand the command (and the word "egg") I see

Page Break 273

the concept of an egg before my mind's eye.

Page 273

When I make an application of the concept "egg" or "plant" there certainly isn't some general picture in front of my mind before I do so, and when I hear the word "plant" it isn't that there comes before my mind a picture of a certain object which I then describe as a plant. No, I make the application as it were spontaneously. Still, in the case

of certain applications I might say "No, I didn't mean that by 'plant'", or, "Yes, I meant that too". But does that mean that these pictures came before my mind and that mentally I expressly rejected and admitted them?--And yet that is what it looks like, when I say: "Yes, I meant all those things, but not *that*." But one might then ask: "But did you foresee all those cases?" and then the answer might be "yes" or "no, but I imagined there must be something between this form and that one" or the like. But commonly at that moment I did not draw any bounds, and they can only be produced in a roundabout way after reflection. For instance, I say "Bring me a flower about so big"; he brings one and I say: Yes, that is the size I meant. Perhaps I do remember a picture which came before my mind, but it isn't that that makes the flower that has been brought acceptable. What I am doing is making an application of the picture, and the application was not anticipated.

Page 273

The only thing of interest to us is the *exact* relationship between the example and the behaviour that accords with it.

Page 273

The example is the point of departure for further calculation.

Page 273

Examples are decent signs, not rubbish or hocus-pocus.

Page 273

The only thing that interests us is the geometry of the mechanism. (That means, the grammar of its description.)

Page 273

But how does it come out in our rules, that the instances of $f(x)$

Page Break 274

we are dealing with are not essentially closed classes?--Only indeed in the generality of the general rule.--How does it come out that they don't have the same significance for the calculus as a closed group of primitive signs (like the names of the 6 basic colours)? How else could it come out except in the rules given for them?--Suppose that in some game I am allowed to help myself to as many pieces as I like of a certain kind, while only a limited number of another kind is available; or suppose a game is unbounded in time but spatially bounded, or something similar. The case is exactly the same. The distinction between the two different types of piece in the game must be laid down in the rules; they will say about the one type that you can take as many pieces as you want of that kind. And I mustn't look for another more restrictive expression of that rule.

Page 274

That means that the expression for the unboundedness of the particular instances in question will be a general expression; there cannot be some other expression in which the other unconsidered instances appear in some shadowy way.

Page 274

It is clear that I do not recognize any logical sum as a definition of the proposition "the cross is between the lines". And that says everything that is to be said.

Page 274

There is one thing I always want to say to clarify the distinction between instances that are offered as examples for a concept and instances that make up a definite closed group in the grammar. Suppose, after explaining "a, b, c, d are books", someone says "Now bring me a book". If the person brings a book which isn't one of the ones shown him he can still be said to have acted correctly in accordance with the rule given. But if what had been said was "a, b, c, d, are my books.--Bring me one of my books", it would have been incorrect to bring a different one and he would have been told "I told you that a, b, c, d are my books". In the first case it isn't against the rule to bring an object other than those named,

Page Break 275

in the second case it is. But if in the order you named only a, b, c, and d, and yet you regarded the behaviour $f(e)$ as obeying the order, doesn't that mean that by $F(a, b, c, d, \dots)$ you meant $F(a, b, c, d, e)$ after all? Again, how are these orders distinct from each other if the same thing obeys both of them?--But $f(g)$ too would have been in accordance with the order and not only $f(e)$. Right, then your first order must have meant $F(a, b, c, d, e, g)$ etc. Whatever you bring me is something I could have included in a disjunction. So if we construct the disjunction of all the cases we actually use, how would it differ syntactically from the general proposition? For we can't say: by the fact that the general proposition is also made true by r (which doesn't occur in the disjunction), because that doesn't distinguish the general proposition from a disjunction which contains r . (And every other similar answer too is impossible.) But it will make sense to say: $F(a, b, c, d, e)$ is the disjunction of all the cases we have actually used, but there are also

other cases (we won't of course, mention any) that make true the general proposition "F(a, b, c, d,...)". And here of course we can't put the general proposition in place of F(a, b, c, d, e,).

Page 275

It is, by the way, a very important fact that the parenthesis in the previous paragraph "and every other similar answer too is impossible" is senseless, because though you can give as instances of a generalization different particular cases, you can't give different variables because the variables r, s, t don't differ in their meaning.

Page 275

Of course one couldn't say that when we do f(d) we don't obey f(\exists) in the same way as we obey a disjunction containing f(d), because $f(\exists) = f(\exists) \vee f(d)$. If you give someone the order "bring me some plant or other, or this one" (giving him a picture of it), he will simply discard the picture and say to himself "since any one will do, the picture doesn't matter". By contrast, we won't simply

Page Break 276

discard the picture if we are given it plus five others and the order to bring one of these six plants. (So what matters is *which* disjunction contains the particular command.) And you wouldn't be guided in the same way by the order "f(a) \vee f(b) \vee f(c)" as by the order "f(\exists)" (= $f(\exists) \vee f(c)$), even if in each case you do f(c).--The picture f(c) sinks into f(\exists). (It is no good sitting in a boat, if you and it are under water and sinking). Someone may be inclined to say: "Suppose you do f(c) on the command f(\exists); in that case f(c) might have been expressly permitted and then how would the general command have differed from a disjunction?"--But if the permission had occurred in a disjunction with the general sentence, you couldn't have *appealed* to it.

Page 276

So is this how it is: "bring me a flower" can never be replaced by an order of the form "bring me a or b or c", but must always be "bring me a or b or c *or some other flower*"?

Page 276

But why does the general sentence behave so indeterminately when every case which actually occurs is something I could have described in advance?

Page 276

But even that seems to me not to get to the heart of the matter; because what matters, I believe, isn't really the infinity of the possibilities, but a kind of indeterminacy. Indeed, if I were asked how many possibilities a circle in the visual field has of being within a particular square, I could neither name a finite number, nor say that there were infinitely many (as in a Euclidean plane). Here, although we don't ever come to an end, the series isn't endless in the way in which $|1, \xi, \xi + 1|$ is.

Page 276

Rather, no end to which we come is really the end; that is, I could always say: I don't understand why these should be all the possibilities.--And doesn't that just mean that it is senseless to speak of "all the possibilities"? So enumeration *doesn't touch* the concepts "plant" and "egg" at all.

Page Break 277

Page 277

And although we say that we could always have foreseen f(a) as a possible particular execution of the order, still we didn't in fact ever do so.--But even if I do foresee the possibility f(a) and expressly include it in my order, it gets lost beside the general proposition, because I can see from the general proposition itself that this particular case is permitted; it isn't just from its being expressly permitted in the order that I see this. If the general proposition is there, the addition of the particular case isn't any extra use to me (that is, it doesn't make the command more explicit). Indeed it was only the general proposition that gave me the justification for placing this particular case beside it. What my whole argument is aiming at, is that someone might believe that the addition of the particular case supersedes the--as it were blurred--generality of the proposition, that you could say "we don't need it any more, now we have the particular case." Yes, but say I admit that the reason I put in the particular case is that it agrees with the general proposition! Or suppose I admit that I recognize that f(a) is a particular case of f(\exists)! For I can't say: that just means that f(\exists) is a disjunction with f(a) as one of its terms; for if that is so, the disjunction must be capable of being stated, and f(\exists) must be defined as a disjunction. There would be no difficulty in giving such a definition, but it wouldn't correspond to the use of f(\exists) that we have in mind. It isn't that the disjunction always leaves something over; it is that it just doesn't touch the essential thing in generality, and even if it is added to it it depends on the general proposition for its justification.

Page 277

First I command f(\exists); he obeys the order and does f(a). Then I think that I could just as well have given him the command "f(\exists) \vee f(a)". (For I knew in advance that f(a) obeyed the order f(\exists) and to command him f(\exists) \vee f(a)

would come to the same.) In that case when he obeyed the order he would have been acting on the disjunction "do something or $f(a)$ ". And if he obeys the order

Page Break 278

by doing $f(a)$ isn't it immaterial what else is disjoined with $f(a)$? If he does $f(a)$ in any case, the order is obeyed whatever the alternative is.

Page 278

I would also like to say: in grammar nothing is supplementary, no stipulations come *after* others, everything is there simultaneously.

Page 278

Thus I can't even say that I first gave the command $f(\exists)$ and only later realised that $f(a)$ was a case of $f(\exists)$; at all events my order was and remained $f(\exists)$ and I added $f(a)$ to it in the knowledge that $f(a)$ was in accordance with $f(\exists)$. And the stipulation that $f(a)$ is in accordance with $f(\exists)$ presupposes the sense that belongs to the proposition $f(\exists)$ if it is taken as an independent unit and not defined as replaceable by a disjunction. And my proposition "at all events my order was and remained $f(\exists)$ etc." only means that I didn't replace the general order by a disjunction.

Page 278

Suppose I give the order $p \vee f(a)$, and the addressee doesn't clearly understand the first part of the order but does understand that the order goes "... $\vee f(a)$ ". He might then do $f(a)$ and say "I know for certain that I've obeyed the command, even though I didn't understand the first part". And that too is how I imagine it when I say that the other alternative doesn't matter. But in that case he didn't obey the order *that was given*, but simply treated it as " $f(a)$!" One might ask: if someone does $f(a)$ at the command " $f(\exists) \vee f(a)$ " is he obeying the order because (i.e. in so far as) the order is of the form $\xi \vee f(a)$, or because $f(\exists) \vee f(a) = f(\exists)$? If you understand $f(\exists)$ and therefore know that $f(\exists) \vee f(a) = f(\exists)$, then by doing $f(a)$ you are obeying $f(\exists)$ even if I write it " $f(\exists) \vee f(a)$ " because you can see *none the less* that $f(a)$ is a case of $f(\exists)$. And now someone might object: if you see that Fa is a case of $F(\exists)$ that just means that $f(a)$ is contained disjunctively in $f(\exists)$, and therefore that $f(\exists)$ is defined *by means of* $f(a)$. The remaining parts of the disjunction--he will have to say--don't concern me because the terms I see are the only ones I now need.--By explaining 'that $f(a)$ is an instance of $f(\exists)$ ' you have said no more than that $f(a)$ occurs in $f(\exists)$ alongside certain other terms.--But that is precisely what we don't mean. It isn't as if our stipulation was an *incomplete definition* of $f(\exists)$;

Page Break 279

for that would mean that a complete definition was *possible*. That would be the disjunction which would make the addition " $\vee f(\exists)$ " as it were ridiculous, since it would only be the enumerated instances which concerned us. But according to our idea of $f(\exists)$, the stipulation that $f(a)$ is a case of $f(\exists)$ is not an incomplete definition of $f(\exists)$; it is not a definition of $f(\exists)$ at all. That means that I don't approximate to the sense of $f(\exists)$ by multiplying the number of cases in the disjunction; though the disjunction of the cases $\vee f(\exists)$ is equivalent to $f(\exists)$, it is never equivalent to the disjunction of the cases alone; it is a totally different proposition.

Page 279

What is said about an enumeration of individual cases cannot ever be a roundabout explanation of generality.

Page 279

But can I give the rules of entailment that hold in this case? How do I know that $(\exists x).fx$ does follow from fa ? After all I can't give *all* the propositions from which it follows.--But that isn't necessary; if $(\exists x).fx$ follows from fa , *that* at any rate was something that could be known in advance of any particular experience, and stated in the grammar.

Page 279

I said "in advance of any experience it was possible to know and to state in the grammar that $(\exists x).fx$ follows from fa ". But it should have been: ' $(\exists x).fx$ follows from fa ' is not a proposition (empirical proposition) of the language to which ' $(\exists x).fx$ ' and ' fa ' belong; it is a rule laid down in their grammar.

Page Break 280

Page 280

We can of course set up a rule for the use of the variables, and the fact that in order to do so we need the same kind of variable does not make it pleonastic. For if we didn't use it, then the variable would be defined by the rules, and we don't assume that it can be defined, or that it must be defined (for sooner or later definitions come to an end).

This means only that--e.g.--the variable "x²" is not an abbreviation (say for a logical sum), and that in our thought too there is only a sign for this multiplicity.

For suppose I had enumerated 7 particular instances and said "but their logical sum isn't the general proposition" that still wouldn't be enough; and I want to say further that no other number of instances yields the general proposition either. But in this rider once again I seem to go through an enumeration, in a kind of shadowy manner if not in actuality. But that is not the way it is, because the words that occur in the rider are quite different from the numerals.

"But how can I forbid a particular numeral to be inserted in such and such a place? I surely can't foresee what number someone will want to insert, so that I can forbid it". You can forbid it when it comes.--But here we are already speaking of the general concept of number!

But what makes a sign an expression of infinity? What gives the peculiar character that belongs to what we call infinite? I believe that it is like the case of a sign for an enormous number. For the characteristic of the infinite, conceived in this way, is its enormous size.

But there isn't anything that is an enumeration and yet not an enumeration; a generality that enumerates in a cloudy kind of

way without really enumerating or enumerating to a determined limit.

The dots in "1 + 1 + 1 + 1..." are just the four dots: a sign, for which it must be possible to give certain rules. (The same rules, in fact, as for the sign "and so on ad inf.") This sign does in a manner ape enumeration, but it isn't an enumeration. And that means that the rules governing it don't totally agree with those which govern an enumeration; they agree only up to a point.

There is no third thing between the particular enumeration and the general sign.

Of course the natural numbers have only been written down up to a certain highest point, let's say 10¹⁰. Now what constitutes the *possibility* of writing down numbers that have not yet been written down? How odd is this feeling that they are all somewhere already in existence! (Frege said that before it was drawn a construction line was in a certain sense already there.)

The difficulty here is to fight off the thought that possibility is a kind of shadowy reality.

In the rules for the variable *a* a variable *b* may occur and so may particular numerals; but not any totality of numbers.

But now it seems as if this involved *denying the existence* of something in logic: perhaps generality itself, or what the dots indicate; whatever is incomplete (loose, capable of further extension) in the number series. And of course we may not and cannot deny the existence of anything. So how does this indeterminacy find expression? Roughly thus: if we introduce numbers substitutable for the variable *a*, we don't say of any of them that it is the last, or the highest.

But suppose someone asked us after the explanation of a form of calculation "and is 103 the last sign I can use?" What are we to answer? "No, it isn't the last" or "there isn't a last?" Mustn't I ask him in turn "If it isn't the last, what would come next?" And if he then says "104" I should say "Quite right, you can continue the series yourself".

Of an end to the possibility, I cannot speak at all.

(In philosophy the one thing we must guard against is waffle. A rule that can be applied in practice is always in order.)

It is clear that we can follow a rule like $|a, \xi, \xi + 1|$. I mean by really following the rule for constructing it without previously being able to write down the series. In that case it's the same as if I were to begin a series with a number like 1 and then say "now add 7, multiply by 5, take the square root of the result, and always apply this complex operation once again to the result". (That would be the rule $|1, \xi, \sqrt{(\xi + 7) \cdot 5}|$.)

The expression "and so on" is nothing but the *expression "and so on"* (nothing, that is, but a sign in a calculus which can't do more than have meaning via the rules that hold of it; which can't say more than it shows).

That is, the expression "and so on" does not harbour a secret power by which the series is continued without being continued.

Of course it doesn't contain *that*, you'll say, but still it contains the meaning of infinite continuation.

But we might ask: how does it happen that someone who now applies the general rule to a further number is still following *this* rule? How does it happen that no further rule was necessary

to allow him to apply the general rule to this case in spite of the fact that this case was not mentioned in the general rule?

And so we are puzzled that we can't bridge over this abyss between the individual numbers and the general proposition.

"Can one imagine an empty space?" (Surprisingly, this is where this question belongs.)

It is one of the most deep rooted mistakes of philosophy to see possibility as a shadow of reality.

But on the other hand it can't be an error; not even if one calls the proposition such a shadow.

Here again, of course, there is a danger of falling into a *positivism*, of a kind which deserves a special name, and hence of course must be an error. For we must avoid accepting party lines or particular views of things; we must not disown anything that anyone has ever said on the topic, except where he himself had a particular view or theory.

For the sign "and so on", or some sign corresponding to it, is essential if we are to indicate endlessness--through the rules, of course, that govern such a sign. That is to say, we can distinguish the limited series "1, 1 + 1, 1 + 1 + 1" from the series "1, 1 + 1, 1 + 1 + 1 and so on". And this last sign and its use is no less essential for the calculus than any other.

What troubles me is that the "and so on" apparently has to occur also in the rules for the sign "and so on". For instance, 1, 1 + 1 and so on. = 1, 1 + 1, 1 + 1 + 1 and so on, *and so on*.

But then isn't this simply the old point that we can describe language only from the outside? So that we can't expect by describing language to penetrate to depths deeper than language

itself reveals: for it is by means of language that we describe language.

We might say: there's no occasion to be afraid of our using the expression "and so on" in a way that transcends the finite.

Moreover, the distinctive part of the grammar of "and so on" can't consist in rules connecting "and so on" with particular numerals (not *the* particular numerals)--for these rules in turn mention some bit of a series--but in rules connecting "and so on" with "and so on".

The possibility of introducing further numbers. The difficulty seems to be that the numbers I've in fact introduced aren't a group that is essential and yet there is nothing to indicate that they are an *arbitrary* collection:

Out of all numbers just those numbers that happen to have been written down.

Page 284
(As if I had all the pieces of a game in a box and a chance selection from the box on the table beside it.

Page 284
Or, as if one lot of numerals was traced in ink, while all of them are as it were drawn faintly in advance.)

Page 284
But apart from the ones we happen to have used we have only the general form.

Page 284
Isn't it here, by the way,--odd as it may sound--that the distinction between numerals and numbers comes?

Page 284
Suppose, for example, I say "By 'cardinal number' I mean whatever results from 1 by continued addition of 1". The word "continued" doesn't represent a nebulous continuation of 1, 1 + 1, 1 + 1 + 1; on the contrary the sign "1, 1 + 1, 1 + 1 + 1..." is to be taken as perfectly exact; governed by definite rules which are different from those for "1, 1 + 1, 1 + 1 + 1", and not a substitute for a series "which cannot be written down".

Page Break 285

Page 285
In other words: we calculate with the sign "1, 1 + 1, 1 + 1 + 1 ..." just as with the numerals, but in accordance with different rules.

Page 285
But what is it then that we imagine? What is the mistake we make? What kind of thing do we take the sign "1, 1 + 1..." to be? That is: where does what we think we see in this sign *really* occur? Something like when I say "he counted 1, 2, 3, 4 and so on up to 1000", where it would also be possible really to write down all the numbers.

Page 285
What do we *see* "1, 1 + 1, 1 + 1 + 1 ..." as?

Page 285
As an inexact form of expression. The dots are like extra numerals indistinctly visible. It is as if we stopped writing numerals, because after all we can't write them all down, but as if they are there all right in a kind of box. Again, it is something like when I sing only the first notes of a melody distinctly, and then merely hint at the rest and let it taper off into nothing. (Or when in writing one writes only a few letters of a word distinctly and ends with an unarticulated line.) *In all such cases the 'indistinctly' has a 'distinctly' corresponding to it.*

Page 285
I once said that there couldn't be both numbers *and* the concept of number. And that is quite correct, if it means that a variable doesn't have the same relation to a number as the concept apple has to an apple (or the concept sword to Nothung [[sic]]).

Page 285
On the other hand, *a number-variable is not a numeral.*

Page 285
But I also wanted to say that the concept of number couldn't be given independently of the numbers, and that isn't true. A number-variable is independent of particular numbers in the sense that there does exist a calculus with a class of our numerals and without the general number-variable. In that calculus, of course, not all the rules which hold of our numerals will be valid, but those numerals will correspond to ours in the way that the draughtsmen in draughts correspond to those in losing draughts.

Page 285
What I am opposing is the view that the infinite number series is

Page Break 286

something given concerning which there are both particular number theorems and also general theorems about all numbers of the series; so that the arithmetical calculus wouldn't be complete if it didn't contain the general theorems about cardinal numbers, i.e. general equations of the form $a + (b + c) = (a + b) + c$. Whereas even $1/3 = 0.\dot{3}$ belongs to a different calculus from $1/3 = 0 \cdot 3$. And similarly a general sign-rule (e.g. a recursive definition) that holds for 1, (1) + 1, ((1) + 1) + 1, (((1) + 1) + 1) + 1, and so on is something different from a particular definition. The general rule adds to the number calculus something extra, without which it would have been no less complete than the arithmetic of the number series 1, 2, 3, 4, 5.

Page 286
The question also arises: where is the concept of number (or of cardinal number) indispensable? Number, in

contrast to what? $|/ 1, \xi, \xi + 1|$, perhaps, in contrast to $|5, \sqrt{5}|$ etc.--For if I really do introduce such a sign (like $|1, \xi, \xi + 1|$) and don't just take it along as a luxury, then I must do something with it, i.e. use it in a calculus, and then it loses its solitary splendour and occurs in a system of signs coordinated with it.

Page 286

You will perhaps say: but surely "cardinal number" is contrasted with "rational number", "real number", etc. But this distinction is a distinction between the rules (the rules of the appropriate game)--not a distinction between positions on the chessboard--not a distinction demanding different coordinated words in the same calculus.

Page 286

We say "this theorem is proved for all cardinal numbers". But let us just see how the concept of cardinal numbers enters into the proof. Only because 1 and the operation $\xi + 1$ are spoken of in the proof--not in contrast to anything the rational numbers have. So if we use the concept-word "cardinal number" to describe the proof in prose, we see--don't we?--that no *concept* corresponds to that word.

Page Break 287

Page 287

The expressions "the cardinal numbers", "the real numbers", are extraordinarily misleading except where they are used to help specify particular numbers, as in "the cardinal numbers from 1 to 100", etc. There is no such thing as "the cardinal numbers", but only "cardinal numbers" and the concept, the form "cardinal number". Now we say "the number of the cardinal numbers is smaller than the number of the real numbers" and we imagine that we could perhaps write the two series side by side (if only we weren't weak humans) and then the one series would end in endlessness, whereas the other would go on beyond it into the actual infinite. But this is all nonsense. If we can talk of a relationship which can be called by analogy "greater" and "smaller", it can only be a relationship between the forms "cardinal number" and "real number". I learn what a series is by having it explained to me and only to the extent that it is explained to me. A finite series is explained to me by examples of the type 1, 2, 3, 4, and infinite one by signs of the type "1, 2, 3, 4, and so on" or "1, 2, 3, 4..."

Page 287

It is important that I can understand (see) the rule of projection without having it in front of me in a general notation. I can detect a general rule in the series $1/1, 2/4, 3/9, 4/16$ --of course I can detect any number of others too, *but still I can detect a particular one*, and that means that this series was somehow for me the expression of that one rule.

Page 287

If you have "intuitively" understood the law of a series, e.g. the series m , so that you are able to construct an arbitrary term $m(n)$, then you've completely understood the law, just as well as anything like an algebraic formulation could convey it. That is, no such formulation can now make you understand it better, and therefore to that extent no such formulation is any more rigorous, although it may of course be easier to take in.

Page 287

We are inclined to believe that the notation that gives a series by writing down a few terms plus the sign "and so on" is essentially inexact, by contrast with the specification of the general term.

Page Break 288

Page 288

Here we forget that the general term is specified by reference to a basic series which cannot in turn be described by a general term. Thus $2n + 1$ is the general term of the odd numbers, *if* n ranges over the cardinal numbers, but it would be nonsense to say that n was the general term of the series of cardinal numbers. If you want to define that series, you can't do it by specifying "the general term n ", but of course only by a definition like "1, 1 + 1, 1 + 1 + 1 and so on". And of course there is no essential difference between that series and "1, 1 + 1 + 1, 1 + 1 + 1 + 1 and so on", which I could just as well have taken as the basic series (so that then the general term of the cardinal number series would have been $\frac{1}{2}(n-1)$.)

$$(\exists x).\phi x: \sim(\exists x, y).\phi x.\phi y$$

$$(\exists x, y).\phi x.\phi y: \sim(\exists x, y, z).\phi x.\phi y.\phi z$$

$$(\exists x, y, z).\phi x.\phi y.\phi z: \sim(\exists x, y, z, u).\phi x.\phi y.\phi z.\phi u$$

"How would we now go about writing the general form of such propositions? The question manifestly has a good sense. For if I write down only a few such propositions as examples, you understand what the *essential element* in these propositions is meant to be."

Page 288

Well, in that case the row of examples is already a notation: for understanding the series consists in our

applying the symbol, and distinguishing it from others in the same system, e.g. from

- ($\exists x$). ϕx
- ($\exists x, y, z$). $\phi x.\phi y.\phi z$
- ($\exists x, y, z, u, v$). $\phi x.\phi y.\phi z.\phi u.\phi v$

Page 288

But why shouldn't we write the general term of the first series thus:

$$(\exists x_1 \dots x_n) \cdot \prod_{x_1}^{x_n} \phi x \cdot (\exists x_1 \dots x_{n+1}) \cdot \prod_{x_1}^{x_{n+1}} \phi x \quad ?\dagger 1$$

Page 288

Is this notation inexact? It isn't supposed by itself to make anything graphic; all that matters are the rules for its use, the system in which it is used. The scruples attaching to it date from a train of thought which was concerned with the number of primitive signs in the calculus of *Principia Mathematica*.

Page Break 289

III FOUNDATIONS OF MATHEMATICS

11

The comparison between mathematics and a game

Page 289

What are we taking away from mathematics when we say it is only a game (or: it is a game)?

Page 289

A game, in contrast to what?--What are we awarding to mathematics if we say it isn't a game, its propositions have a sense?

Page 289

The sense outside the proposition.

Page 289

What concern is it of ours? Where does it manifest itself and what can we do with it? (To the question "what is the sense of this proposition?" the answer is a proposition.)

Page 289

("But a mathematical proposition does express a thought."--What thought?--.)

Page 289

Can it be expressed by another proposition? Or only by *this* proposition?--Or not at all? In that case it is no concern of ours.

Page 289

Do you simply want to distinguish mathematical propositions from other constructions, such as hypotheses? You are right to do so: there is no doubt that there is a distinction.

Page 289

If you want to say that mathematics is played like chess or patience, and the point of it is like winning or coming out, that is manifestly incorrect.

Page 289

If you say that the mental processes accompanying the use of mathematical symbols are different from those accompanying chess, I wouldn't know what to say about that.

Page 289

In chess there are some positions that are impossible although each individual piece is in a permissible position. (E.g. if all the pawns are still in their initial position, but a bishop is already in

Page Break 290

play.) But one could imagine a game in which a record was kept of the number of moves from the beginning of the game and then there would be certain positions which could not occur after n moves and yet one could not read off from a position by itself whether or not it was a possible nth position.

Page 290

What we do in games must correspond to what we do in calculating. (I mean: it's there that the correspondence must be, or again, that's the way that the two must be correlated with each other.)

Page 290

Is mathematics about signs on paper? No more than chess is about wooden pieces.

Page 290

When we talk about the sense of mathematical propositions, or what they are about, we are using a false picture. Here too, I mean, it looks as if there are inessential, arbitrary signs which have an essential element in common, namely the sense.

Page 290

Since mathematics is a calculus and hence isn't really *about* anything, there isn't any metamathematics.

Page 290

What is the relation between a chess problem and a game of chess?--It is clear that chess problems correspond to arithmetical problems, indeed that they are arithmetical problems.

Page 290

The following would be an example of an arithmetical game: We write down a four-figure number at random, e.g. 7368; we are to get as near to this number as possible by multiplying the numbers 7, 3, 6, 8 with each other in any order. The players calculate with pencil and paper, and the person who comes nearest to the number 7368 in the smallest number of steps wins. (Many mathematical puzzles, incidentally, can be turned into games of this kind.)

Page 290

Suppose a human being had been taught arithmetic only for use in an arithmetical game: would he have learnt something different from a person who learns arithmetic for its ordinary use? If he multiplies 21 by 8 in the game and gets 168, does he do something

Page Break 291

different from a person who wanted to find out how many 21×8 is?

Page 291

It will be said: the one wanted to find out a truth, but the other did not want to do anything of the sort.

Page 291

Well, we might want to compare this with a game like tennis. In tennis the player makes a particular movement which causes the ball to travel in a particular way, and we can view his hitting the ball either as an experiment, leading to the discovery of a particular truth, or else as a stroke with the sole purpose of winning the game.

Page 291

But this comparison wouldn't fit, because we don't regard a move in chess as an experiment (though that too we might do); we regard it as a step in a calculation.

Page 291

Someone might perhaps say: In the arithmetical game we do indeed do the multiplication $(21 \times 8)/168$, but the equation $21 \times 8 = 168$ doesn't occur in the game. But isn't that a superficial distinction? And why shouldn't we multiply (and of course divide) in such a way that the equations were written down as equations?

Page 291

So one can only object that in the game the equation is not a proposition. But what does that mean? How does it become a proposition? What must be added to it to make it a proposition?--Isn't it a matter of the use of the equation (or of the multiplication)?--And it is certainly a piece of mathematics when it is used in the transition from one proposition to another. And thus the specific difference between mathematics and a game gets linked up with the concept of proposition (not 'mathematical proposition') and thereby loses its actuality for us.

Page 291

But one could say that the real distinction lay in the fact that in the game there is no room for affirmation and negation. For

Page Break 292

instance, there is multiplication and $21 \times 8 = 148$ would be a false move, but " $(21 \times 8 = 148)$ ", which is a correct arithmetical proposition, would have no business in our game.

Page 292

(Here we may remind ourselves that in elementary schools they never work with inequations. The children are only asked to carry out multiplications correctly and never--or hardly ever--asked to prove an inequation.)

Page 292

When I work out 21×8 in our game the steps in the calculation, at least, are the same as when I do it in order to solve a practical problem (and we could make room in a game for inequations also). But my attitude to the sum in other respects differs in the two cases.

Now the question is: can we say of someone playing the game who reaches the position " $21 \times 8 = 168$ " that he has found out that 21×8 is 168? What does he lack? I think the only thing missing is an application for the sum.

Calling arithmetic a game is no more and no less wrong than calling moving chessmen according to chess-rules a game; for that might be a calculation too.

So we should say: No, the word "arithmetic" is not the name of a game. (That too of course is trivial)--But the meaning of the word "arithmetic" can be clarified by bringing out the relationship between arithmetic and an arithmetical game, or between a chess problem and the game of chess.

But in doing so it is *essential* to recognize that the relationship is not the same as that between a tennis problem and the game of tennis.

By "tennis problem" I mean something like the problem of returning a ball in a particular direction in given circumstances. (A billiard problem would perhaps be a clearer case.) A billiard problem isn't a mathematical problem (although its solution may be an application of mathematics). A billiard problem is a physical

problem and therefore a "problem" in the sense of physics; a chess problem is a mathematical problem and so a "problem" in a different sense, a mathematical sense.

In the debate between "formalism" and "contentful mathematics" what does each side assert? This dispute is so like the one between realism and idealism in that it will soon have become obsolete, for example, and in that both parties make unjust assertions at variance with their day-to-day practice.

Arithmetic *isn't* a game, it wouldn't occur to anyone to include arithmetic in a list of games played by human beings.

What constitutes winning and losing in a game (or success in patience)? It isn't of course, just the winning position. A special rule is needed to lay down who is the winner. ("Draughts" and "losing draughts" differ only in this rule.)

Now is the rule which says "The one who first has his pieces in the other one's half is the winner" a statement? How would it be verified? How do I know if someone has won? Because he is pleased, or something of the kind? Really what the rule says is: you must try to get your pieces as soon as possible, etc.

In this form the rule connects the game with life. And we could imagine that in an elementary school in which one of the subjects taught was chess the teacher would react to a pupil's bad moves in exactly the same way as to a sum worked out wrongly.

I would almost like to say: It is true that in the game there isn't any "true" and "false" but then in arithmetic there isn't any "winning" and "losing".

I once said that it was imaginable that wars might be fought on a kind of huge chessboard according to the rules of chess. But if everything really went simply according to the rules of chess, then you wouldn't need a battlefield for the war, it could be played on an ordinary board; and then it wouldn't be a war in the ordinary sense. But you really could imagine a battle conducted in accordance with the rules of chess--if, say, the "bishop" could fight with the "queen" only when his position in relation to her was such that he would be allowed to "take" her in chess.

Could we imagine a game of chess being played (i.e. a complete set of chess moves being carried out) in such *different surroundings* that what happened wasn't something we could call the playing of a game?

Certainly, it might be a case of the two participants collaborating to solve a *problem*. (And we could easily

construct a case on these lines in which such a task would have a utility).

Page 294

The rule about winning and losing really just makes a distinction between two poles. It is not concerned with what later happens to the winner (or loser)--whether, for instance, the loser has to pay anything.

Page 294

(And similarly, the thought occurs, with "right" and "wrong" in sums.)

Page 294

In logic the same thing keeps happening as happened in the dispute about the nature of definition. If someone says that a definition is concerned only with signs and does no more than substitute one sign for another, people resist and say that that isn't *all* a definition does, or that there are different kinds of definition and the interesting and important ones aren't the mere "verbal definitions".

Page 294

They think, that is, that if you make definition out to be a mere substitution rule for signs you take away its significance and importance. But the *significance* of a definition lies in its application, in its importance for life. The same thing is happening today in the

Page Break 295

dispute between formalism and intuitionism, etc. People cannot separate the importance, the consequences, the application of a fact from the fact itself; they can't separate the description of a thing from the description of its importance.

Page 295

We are always being told that a mathematician works by instinct (or that he doesn't proceed mechanically like a chessplayer or the like), but we aren't told what that's supposed to have to do with the nature of mathematics. If such a psychological phenomenon does play a part in mathematics we need to know how far we can speak about mathematics with complete exactitude, and how far we can only speak with the indeterminacy we must use in speaking of instincts etc.

Page 295

Time and again I would like to say: What *I* check is the *account books* of mathematicians; their mental processes, joys, depressions and instincts as they go about their business may be important in other connections, but they are no concern of mine.

Page Break 296

12

There is no metamathematics.

Page 296

No calculus can decide a philosophical problem.

Page 296

A calculus cannot give us information about the foundations of mathematics.

Page 296

So there can't be any "leading problems" of mathematical logic, if those are supposed to be problems whose solution would at long last give us the right to do arithmetic as we do.

Page 296

We can't wait for the lucky chance of the solution of a mathematical problem.

Page 296

I said earlier "calculus is not a mathematical concept"; in other words, the word "calculus" is not a chesspiece that belongs to mathematics.

Page 296

There is no need for it to occur in mathematics.--If it is used in a calculus nonetheless, that doesn't make the calculus into a metacalculus; in such a case the word is just a chessman like all the others.

Page 296

Logic isn't metamathematics either; that is, work within the logical calculus can't bring to light essential truths *about* mathematics. Cf. here the "decision problem" and similar topics in modern mathematical logic.

Page 296

(Through Russell and Whitehead, especially Whitehead, there entered philosophy a false exactitude that is the worst enemy of real exactitude. At the bottom of this there lies the erroneous opinion that a calculus could be the mathematical foundation of mathematics.)

Page 296

Number is not at all a "fundamental mathematical concept"†1.

Page Break 297

There are so many calculations in which numbers aren't mentioned.

Page 297

So far as concerns arithmetic, what we are willing to call numbers is more or less arbitrary. For the rest, what we have to do is to describe the calculus--say of cardinal numbers--that is, we must give its rules and by doing so we lay the foundations of arithmetic.

Page 297

Teach it to us, and then you have laid its foundations.

Page 297

(Hilbert sets up rules of a particular calculus as rules of metamathematics.)

Page 297

A system's being *based on* first principles is not the same as its being developed from them. It makes a difference whether it is like a house resting on its lowest walls or like a celestial body floating free in space which we have begun to build beneath although we might have built anywhere else.

Page 297

Logic and mathematics are not *based on* axioms, any more than a group is based on the elements and operations that define it. The idea that they are involves the error of treating the intuitiveness, the self-evidence, of the fundamental propositions as a criterion for correctness in logic.

Page 297

A foundation that stands on nothing is a bad foundation.

Page 297

$(p.q) \vee (p.\sim q) \vee (\sim p.q) \vee (\sim p.\sim q)$: That is my tautology, and then I go on to say that every "proposition of logic" can be brought into this form in accordance with specified rules. But that means the same as: can be derived from it. This would take us as far as the Russellian method of demonstration and all we add to it

Page Break 298

is that this initial form is not itself an independent proposition, and that like all other "laws of logic" it has the property that $p.\text{Log} = p$, $p \vee \text{Log} = \text{Log}$.

Page 298

It is indeed the essence of a "logical law" that when it is conjoined with any proposition it yields that proposition. We might even begin Russell's calculus with definitions like

$$p \supset p.q. = .q$$
$$p:p \vee q. = .p, \text{ etc.}$$

Page Break 299

Page 299

If we prove that a problem can be solved, the concept "solution" must occur somewhere in the proof. (There must be something in the mechanism corresponding to the concept.) But the concept cannot have an external description as its proxy; it must be genuinely spelt out.

Page 299

The only proof of the provability of a proposition is a proof of the proposition itself. But there is something we might call a proof of relevance: an example would be a proof convincing me that I *can* verify the equation $17 \times 38 = 456$ before I have actually done so. Well, how is it that I know that I can check $17 \times 38 = 456$, whereas I perhaps wouldn't know, merely by looking, whether I could check an expression in the integral calculus? Obviously, it is because I know that the equation is constructed in accordance with a definite rule and because I know the kind of connection between the rule for the solution of the sum and the way in which the proposition is put together. In that case a proof of relevance would be something like a formulation of the general method of doing things like multiplication sums, enabling us to recognize the general form of the propositions it makes it possible to check. In that case I can say I recognise that this method will verify the equation without having actually carried out the verification.

Page 299

When we speak of proofs of relevance (and other similar mathematical entities) it always looks as if in addition to the particular series of operations called proofs of relevance, we had a quite definite inclusive concept of such proofs or of mathematical proof in general; but in fact the word is applied with many different, more or less related, meanings. (Like words such as "people", "king", "religion", etc.; cf Spengler.) Just think of the role of examples in the explanation of such words. If I want to explain what I mean by "proof", I will have to point to examples of proofs,

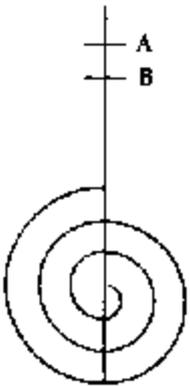

Page Break 300

just as when explaining the word "apple" I point to apples. The definition of the word "proof" is in the same case as the definition of the word "number". I can define the expression "cardinal number" by pointing to examples of cardinal numbers; indeed instead of the expression I can actually use the sign "1, 2, 3, 4, and so on ad inf". I can define the word "number" too by pointing to various kinds of number; but when I do so I am not circumscribing the concept "number" as definitely as I previously circumscribed the concept cardinal number, unless I want to say that it is only the things at present called numbers that constitute the concept "number", in which case we can't say of any new construction that it constructs a kind of number. But the way we want to use the word "proof" in is one in which it isn't simply defined by a disjunction of proofs currently in use; we want to use it in cases of which at present we "can't have any idea". To the extent that the concept of proof is *sharply* circumscribed, it is only through particular proofs, or through series of proofs (like the number series), and we must keep that in mind if we want to speak absolutely precisely about proofs of relevance, of consistency etc.

Page 300

We can say: A proof of relevance *alters* the calculus containing the proposition to which it refers. It cannot *justify* a calculus containing the proposition, in the sense in which carrying out the multiplication 17×23 justifies the writing down of the equation $17 \times 23 = 391$. Not, that is, unless we expressly give the word "justify" that meaning. But in that case we mustn't believe that if mathematics lacks this justification, it is in some more general and widely established sense illegitimate or suspicious. (That would be like someone wanting to say: "the use of the expression 'pile of stones' is fundamentally illegitimate, until we have laid down officially how many stones make a pile." Such a stipulation would modify the use of the word "pile" but it wouldn't "justify" it in any generally recognized sense; and if such an official definition were given, it wouldn't mean that the use earlier made of the word would be stigmatized as incorrect.)

Page Break 301

Page 301

The proof of the verifiability of $17 \times 23 = 391$ is not a "proof" in the same sense of the word as the proof of the equation itself. (A cobbler heels, a doctor heals: both...) We grasp the verifiability of the equation from its proof somewhat as we grasp the verifiability of the proposition "the points A and B are not separated by a turn of the spiral" from the figure. And we see that the proposition stating verifiability isn't a "proposition" in the same sense as the one whose verifiability is asserted. Here again, one can only say: look at the proof, and you will see *what* is proved here, what gets called "the proposition proved".

Page 301

Can one say that at each step of a proof we need a new insight? (The individuality of numbers.) Something of the following sort: if I am given a general (variable) rule, I must recognize each time afresh that this rule may be applied *here* too (that it holds for *this* case too). No act of foresight can absolve me from this act of *insight*. Since the form in which the rule is applied is in fact a new one at every step. But it is not a matter of an act of *insight*, but of an act of *decision*.

Page 301

What I called a proof of relevance does not climb the ladder to its proposition--since that *requires* that you pass every rung--but only shows that the ladder leads in the direction of that proposition.

Page Break 302

(There are no surrogates in logic). Neither is an arrow that points the direction a surrogate for going through all the stages towards a particular goal.

Page Break 303

Consistency proofs

Page 303

Something tells me that a contradiction in the axioms of a system can't really do any harm until it is revealed. We think of a hidden contradiction as like a hidden illness which does harm even though (and perhaps precisely because) it doesn't show itself in an obvious way. But two rules in a game which in a particular instance contradict each other are perfectly in order until the case turns up, and it's only then that it becomes necessary to make a decision between them by a further rule.

Page 303

Mathematicians nowadays make so much fuss about proofs of the consistency of axioms. I have the feeling that if there were a contradiction in the axioms of a system it wouldn't be such a great misfortune. Nothing easier than to remove it.

Page 303

"We may not use a system of axioms before its consistency has been proved."

Page 303

"In the rules of the game no contradictions may occur."

Page 303

Why not? "Because then one wouldn't know how to play."

Page 303

But how does it happen that our reaction to a contradiction is a doubt?

Page 303

We don't have any reaction to a contradiction. We can only say: if it's really meant like that (if the contradiction is *supposed* to be there) I don't understand it. Or: it isn't something I've learnt. I don't understand the sign. I haven't learnt what I am to do with it, whether it is a command, etc.

Page 303

Suppose someone wanted to add to the usual axioms of arithmetic the equation $2 \times 2 = 5$. Of course that would mean that the sign of equality had changed its meaning, i.e. that there would now be different rules for the equals-sign.

Page Break 304

Page 304

If I inferred "I cannot use it as a substitution sign" that would mean that its grammar no longer fitted the grammar of the word "substitute" ("substitution sign", etc.). For the word "can" in that proposition doesn't indicate a physical (physiological, psychological) possibility.

Page 304

"The rules may not contradict each other" is like "negation, when doubled, may not yield a negation". That is, it is part of the grammar of the word "rule" that if "p" is a rule, "p.~p" is not a rule.

Page 304

That means we could also say: the rules may contradict each other, if the rules for the use of the word "rule" are different--if the word "rule" has a different meaning.

Page 304

Here too we cannot give any foundation (except a biological or historical one or something of the kind); all we can do is to establish the agreement, or disagreement between the rules for certain words, and say that these words are used with these rules.

Page 304

It cannot be shown, proved, that these rules *can* be used as the rules of this activity.

Page 304

Except by showing that the grammar of the description of the activity fits the rules.

Page 304

"In the rules there *mustn't* be a contradiction" looks like an instruction: "In a clock the hand *mustn't* be loose on the shaft." We expect a reason: because otherwise... But in the first case the reason would have to be: because otherwise it wouldn't be a set of rules. Once again we have a grammatical structure that cannot be given a logical foundation.

Page 304

In the indirect proof that a straight line can have only *one* continuation through a certain point we make the supposition that a straight line could have two continuations.--If we make that

Page Break 305

supposition, then the supposition must make sense.--But what does it mean to make that supposition? It isn't making a supposition that goes against natural history, like the supposition that a lion has two tails.--It isn't making a supposition that goes against an ascertained fact. What it means is supposing a rule; and there's nothing against that except that it contradicts another rule, and for that reason I drop it.

Page 305

Suppose that in the proof there occurs the following drawing  to represent a straight line bifurcating. There is nothing absurd (contradictory) in that unless we have made some stipulation that it contradicts.

Page 305

If a contradiction is found later on, that means that hitherto the rules have not been clear and unambiguous. So the contradiction doesn't matter, because we can now get rid of it by enunciating a rule.

Page 305

In a system with a clearly set out grammar there are no hidden contradictions, because such a system must include the rule which makes the contradiction is discernible. A contradiction can only be hidden in the sense that it is in the higgledy-piggledy zone of the rules, in the unorganized part of the grammar; and there it doesn't matter since it can be removed by organizing the grammar.

Page 305

Why may not the rules contradict one another? Because otherwise they wouldn't be rules.

Page Break 306

15

Justifying arithmetic and preparing it for its applications
(Russell, Ramsey)

Page 306

One always has an aversion to giving arithmetic a foundation by saying something about its application. It appears firmly enough grounded in itself. And that of course derives from the fact that arithmetic is its own application.

Page 306

You could say: why bother to limit the application of arithmetic, that takes care of itself. (I can make a knife without bothering about what kinds of materials I will have cut with it; that will show soon enough.)

Page 306

What speaks against our demarcating a region of application is the feeling that we can understand arithmetic without having any such region in mind. Or put it like this: our instinct rebels against anything that isn't restricted to an analysis of the thoughts already before us.

Page 306

You could say arithmetic is a kind of geometry; i.e. what in geometry are constructions on paper in arithmetic are calculations (on paper). You could say, it is a more general kind of geometry.

Page 306

It is always a question of whether and how far it's possible to represent the most general form of the application of arithmetic. And here the strange thing is that in a certain sense it doesn't seem to be needed. And if in fact it isn't needed, then it's also impossible.

Page 306

The general form of its application seems to be represented by the fact that nothing is said about it. (And if that's a possible representation, then it is also *the* right one.)

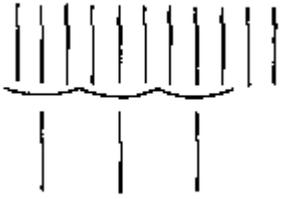

Page 306

The point of the remark that arithmetic is a kind of geometry is simply that arithmetical constructions are autonomous like

geometrical ones and hence so to speak themselves guarantee their applicability.

For it must be possible to say of geometry too that it is its own application.

(In the sense in which we can speak of lines which are possible and lines which are actually drawn we can also speak of possible and actually represented numbers.)

That is an arithmetical construction, and in a *somewhat* extended sense also a geometrical one.

Suppose I wish to use this calculation to solve the following problem: if I have 11 apples and want to share them among some people in such a way that each is given 3 apples how many people can there be? The calculation supplies me with the answer 3. Now suppose I were to go through the whole process of sharing and at the end 4 people each had 3 apples in their hands. Would I then say that the computation gave a wrong result? Of course not. And that of course means only that the computation was not an experiment.

It might look as though the mathematical computation entitled us to make a prediction, say, that I could give three people their share and there will be two apples left over. But that isn't so. What justifies us in making this prediction is an hypothesis of physics, which lies outside the calculation. The calculation is only a study of logical forms, of structures, and of itself can't yield anything new.

If 3 strokes on the paper are the sign for the number 3, then you can say the number 3 is to be applied in our language in the way in which the 3 strokes can be applied.

I said "One difficulty in the Fregean theory is the generality of the words 'Concept' and 'Object'. For, even if you can count

tables, tones, vibrations and thoughts, it is difficult to bracket them all together."†1 But what does "you *can* count them" mean? What it means is that it *makes sense* to apply the cardinal numbers to them. But if we know that, if we know *these* grammatical rules, why do we need to rack our brains about the other grammatical rules when we are only concerned to justify the application of cardinal arithmetic? It isn't difficult "to bracket them all together"; so far as is necessary for the present purpose they are already bracketed together.

But (as we all know well) arithmetic isn't at all concerned about this application. Its applicability takes care of itself.

Hence so far as the foundations of arithmetic are concerned all the anxious searching for distinctions between subject-predicate forms, and constructing functions 'in extension' (Ramsey) is a waste of time.

The equation 4 apples + 4 apples = 8 apples is a substitution rule which I use if instead of substituting the sign "8" for the sign "4 + 4", I substitute the sign "8 apples" for the sign "4 + 4 apples."

But we must beware of thinking that "4 apples + 4 apples = 8 apples" is the concrete equation and $4 + 4 = 8$ the abstract proposition of which the former is only a special case, so that the arithmetic of apples, though much less general than the truly general arithmetic, is valid in its own restricted domain (for apples). There isn't any "arithmetic of apples", because the equation 4 apples + 4 apples = 8 apples is not a proposition about apples. We may say that in this equation the word "apples" has no reference. (And we can always say this about a sign in a rule which helps to determine its meaning.)

How can we make preparations for the reception of something that may happen to exist--in the sense in which Russell and Ramsey always wanted to do this? We get logic ready for the existence of many-placed relations, or for the existence of an infinite number of objects, or the like.

Well, we can make preparations for the existence of a thing: e.g. I may make a casket for jewellery which may be made some time or other--But in this case I can say what the situation must be--what the situation is--for which I am preparing. It is no more difficult to describe the situation now than after it has already occurred; even, if it never occurs at all. (Solution of mathematical problems). But what Russell and Ramsey are making preparations for is a possible grammar.

On the one hand we think that the nature of the functions and of the arguments that are counted in mathematics is part of its business. But we don't want to let ourselves be tied down to the functions now known to us, and we don't know whether people will ever discover a function with 100 argument places; and so we have to make preparations and construct a function to get everything ready for a 100-place relation in case one turns up.--But what does "a 100-place relation turns up (or exists)" mean at all? What concept do we have of one? Or of a 2-place relation for that matter?--As an example of a 2-place relation we give something like the relation between father and son. But what is the significance of this example for the further logical treatment of 2-place relations? Instead of every "aRb" are we now to imagine "a is the father of b"?--If not, is this example or any example essential? Doesn't this example have the same role as an example in arithmetic, when I use 3 rows of 6 apples to explain $3 \times 6 = 18$ to somebody?

Here it is a matter of our concept of *application*.--We have an image of an engine which first runs idle, and then works a machine.

But what does the application add to the calculation? Does it

introduce a new calculus? In that case it isn't any longer *the same* calculation. Or does it give it substance in some sense which is essential to mathematics (logic)? If so, how can we abstract from the application at all, even only temporarily?

No, calculation with apples is essentially the same as calculation with lines or numbers. A machine is an extension of an engine, an application is not in the same sense an extension of a calculation.

Suppose that, in order to give an example, I say "love is a 2-place relation"--am I saying anything about love? Of course not. I am giving a rule for the use of the word "love" and I mean perhaps that we use *this* word in such and such a way.

Yet we do have the feeling that when we allude to the 2-place relation 'love' we put meaning into the husk of the calculus of relations.--Imagine a geometrical demonstration carried out using the cylinder of a lamp instead of a drawing or analytical symbols. How far is this an application of geometry? Does the use of the glass cylinder in the lamp enter into the geometrical thought? And does the use of word "love" in a declaration of love enter into my discussions of 2-place relations?

We are concerned with different uses or meanings of the word "application". "Division is an application of multiplication"; "the lamp is an application of the glass cylinder"; "the calculation is applied to these apples".

At this point we can say: arithmetic is its own application. The calculus is its own application.

In arithmetic we cannot make preparations for a grammatical application. For if arithmetic is only a game, its application too is only a game, and either the same game (in which case it takes us no further) or a different game--and in that case we could play it in pure arithmetic also.

So if the logician says that he has made preparations in arithmetic for the possible existence of 6-place relations, we may ask him: when what you have prepared finds its application, what will be added to it? A new calculus?--but that's something you haven't provided. Or something which doesn't affect the calculus?--then it doesn't interest us, and the calculus you have shown us is application enough.

Page 311

What is incorrect is the idea that the application of a calculus in the grammar of real language correlates it to a reality or gives it a reality that it did not have before.

Page 311

Here as so often in this area the mistake lies not in believing something false, but in looking in the direction of a misleading analogy.

Page 311

So what happens when the 6-place relation is found? Is it like the discovery of a metal that has the desired (and previously described) properties (the right specific weight, strength, etc.)? No; what is discovered is a word that we in fact use in our language as we used, say, the letter R. "Yes, but this word has meaning, and 'R' has none. So now we see that something can correspond to 'R'." But the meaning of the word does not consist in something's corresponding to it, except in a case like that of a name and what it names; but in our case the bearer of the name is merely an extension of the calculus, of the language. And it is *not* like saying "this story really happened, it was not pure fiction".

Page 311

This is all connected with the false concept of logical analysis that Russell, Ramsey and I used to have, according to which we are writing for an ultimate logical analysis of facts, like a chemical analysis of compounds--an analysis which will enable us really

Page Break 312

to discover a 7-place relation, like an element that really has the specific weight 7.

Page 312

Grammar is for us a pure calculus (not the application of a calculus to reality).

Page 312

"How can we make preparations for something which may or may not exist?" means: how can we hope to make an *a priori* construction to cope with all possible results while basing arithmetic upon a logic in which we are still waiting for the results of an analysis of our propositions in particular cases?--One wants to say: "we don't know whether it may not turn out that there are no functions with 4 argument places, or that there are only 100 arguments that can significantly be inserted into functions of *one* variable. Suppose, for example (the supposition does appear possible) that there is only one four-place function F and 4 arguments a, b, c, d; does it make sense in that case to say ' $2 + 2 = 4$ ' since there aren't any functions to accomplish the division into 2 and 2?" So now, one says to oneself, we will make provision for all possible cases. But of course that has no meaning. On the one hand the calculus doesn't make provision for possible existence; it constructs for itself all the existence that it needs. On the other hand what look like hypothetical assumptions about the logical elements (the logical structure) of the world are merely specifications of elements in a calculus; and of course you can make these in such a way that the calculus does not contain any $2 + 2$.

Page 312

Suppose we make preparations for the existence of 100 objects by introducing 100 names and a calculus to go with them. Then let us suppose 100 objects are really discovered. What happens now that the names have objects correlated with them which weren't correlated with them before? Does the calculus change?--What has the correlation got to do with it at all? Does it make it acquire more reality? Or did the calculus previously belong only to mathematics, and now to logic as well?--What sort of questions are "are there 3-place relations", "are there 1000 objects"? How is

Page Break 313

it to be decided?--But surely it is a fact that we can specify a 2-place relation, say love, and a 3-place one, say jealousy, but perhaps not a 27-place one!--But what does "to specify a 2-place relation" mean? It sounds as if we could point to a thing and say "you see, that is the kind of thing" (the kind of thing we described earlier). But nothing of that kind takes place (the comparison with pointing is altogether wrong). "The relation of jealousy cannot be reduced to 2-place relationships" sounds like "alcohol cannot be decomposed into water plus a solid substance". Is that something that is part of the nature of jealousy? (Let's not forget: the proposition "A is jealous of B because of C" is no more and no less reducible than the proposition "A is not jealous of B because of C".) What is pointed to is, say, the group of people A, B and C.--"But suppose that living beings at first knew only plane surfaces, but none the

less developed a 3-dimensional geometry, and that they suddenly became acquainted with 3-dimensional space!" Would this alter their geometry, would it become richer in content?--"Isn't this the way it is? Suppose at some time I had made arbitrary rules for myself prohibiting me from moving in my room in certain directions where there were no physical hindrances to get in my way; and then suppose the physical conditions changed, say furniture was put in the room, in such a way as to force me to move in accordance with the rules which I had originally imposed on myself arbitrarily. Thus, while the 3-dimensional calculus was only a game, there weren't yet three dimensions in reality because the x, y, z belonged to the rules only because I had so decided; but now that we have linked them up to the real 3 dimensions, no other movements are *possible* for them." But that is pure fiction. There isn't any question here of a connection with reality which keeps grammar on the rails. The "connection of language with reality", by means of ostensive definitions and the like, doesn't make the grammar inevitable or provide a justification for the grammar. The grammar remains a free-floating calculus which can only be extended and never supported. The "connection with

Page Break 314

reality" merely extends language, it doesn't force anything on it. We speak of discovering a 27-place relation but on the one hand no discovery can force me to use the sign or the calculus for a 27-place relation, and on the other hand I can describe the operation of the calculus itself simply by using this notation.

Page 314

When it looks in logic as if we are discussing several different universes (as with Ramsey), in reality we are considering different games. The definition of a "universe" in a case like Ramsey's would simply be a definition like

$$(\exists x). \phi x \stackrel{\text{Def}}{=} \phi a \vee \phi b \vee \phi c \vee \phi d.$$

Page Break 315

Ramsey's theory of identity

Page 315

Ramsey's theory of identity makes the mistake that would be made by someone who said that you could use a painting as a mirror as well, even if only for a single posture. If we say this we overlook that what is essential to a mirror is precisely that you can infer from it the posture of a body in front of it, whereas in the case of the painting you have to know that the postures tally before you can construe the picture as a mirror image.

Page 315

If Dirichlet's conception of function has a strict sense, it must be expressed in a *definition* that uses the table to define the function-signs as equivalent.

Page 315

Ramsey defines $\dagger 1$ $x = y$ as

$$(\phi_e) \bullet \phi_e x \exists \phi_e y$$

Page 315

But according to the explanations he gives of his function-sign " ϕ_e "

$(\phi_e) \bullet \phi_e x \exists \phi_e x$ is the statement: "every sentence is equivalent to itself."

$(\phi_e) \bullet \phi_e x \exists \phi_e y$ is the statement: "every sentence is equivalent to every sentence."

So all he has achieved by his definition is what is laid down by the two definitions

$$x = x. \stackrel{\text{Def}}{=} \text{Tautology}$$

$$x = y. \stackrel{\text{Def}}{=} \text{Contradiction}$$

(Here the word "tautology" can be replaced by any arbitrary tautology, and similarly with "contradiction"). So far all that has happened is that definitions have been given of the two distinct signs $x = x$ and $x = y$. These definitions could of course be replaced by two sets of definitions, e.g.

$$\left. \begin{array}{l} a = a \\ b = b \\ c = c \end{array} \right\} = \text{Taut.}$$

$$\left. \begin{array}{l} a = b \\ b = c \\ c = a \end{array} \right\} = \text{Contr.}$$

But then Ramsey writes:

" $(\exists x, y). x \neq y$ ", i.e. " $(\exists x, y). \sim(x = y)$ "--

but he has no right to: for what does the " $x = y$ " mean in this expression? It is neither the sign " $x = y$ " used in the definition above, nor of course the " $x = x$ " in the preceding definition. So it is a sign that is still unexplained. Moreover to see the futility of these definitions, you should read them (as an unbiased person would) as follows: I permit the sign "Taut", whose use we know, to be replaced by the sign " $a = a$ " or " $b = b$ ", etc.; and the sign "Contr." (" \sim Taut.") to be replaced by the sign " $a = b$ " or " $a = c$ ", etc. From which, incidentally, it follows that $(a = b) = (c = d) = (a \neq a) =$ etc.!

It goes without saying that an identity sign defined like that has no resemblance to the one we use to express a substitution rule.

Of course I can go on to define " $(\exists x, y). x \neq y$ ", say as $a \neq a. \vee. a \neq b. \vee. b \neq c. \vee. a \neq c$; but this definition is pure humbug and I should have written straightaway $(\exists x, y). x \neq y. \stackrel{\text{Def}}{=} \text{Taut}$. (That is, I would be given the sign on the left side as a new unnecessary--sign for "Taut.") For we mustn't forget that according to the definitions " $a = a$ ", " $a = b$ ", etc. are independent signs, no more connected with each other than the signs "Taut." and "Contr." themselves.

What is in question here is whether functions in extension are any use; because Ramsey's explanation of the identity sign is just such a specification by extension. Now what exactly is the specification of a function by its extension? Obviously, it is a group of definitions, e.g.

$fa = p$ Def.

$fb = q$ Def.

$fc = r$ Def.

These definitions permit us to substitute for the known propositions "p", "q", "r" the signs "fa" "fb" "fc". To say that these three definitions determine the function $f(\xi)$ is either to say nothing, or to say the same as the three definitions say.

For the signs "fa" "fb" "fc" are no more function and argument than the words "Co(rn)", "Co(al)" and "Co(lt)" are. (Here it makes no difference whether or not the "arguments" "rn", "al", "lt" are used elsewhere as words).

(So it is hard to see what purpose the definitions can have except to mislead us.)

To begin with, the sign " $(\exists x). fx$ " has no meaning; because here the rules for functions in the old sense of the word don't hold at all. According to them a definition like $fa = \dots$ would be nonsense. If no explicit definition is given for it, the sign " $(\exists x). fx$ " can only be understood as a rebus in which the signs have some kind of spurious meaning.

Each of the signs " $a = a$ ", " $a = c$ ", etc. in the definitions $(a = a). \stackrel{\text{Def}}{=} \text{Taut}$. etc. is a *word*.

Moreover, the purpose of the introduction of functions in extension was to analyse propositions about infinite extensions, and it fails of this purpose when a function in extension is introduced by a list of definitions.

There is a temptation to regard the form of an equation as the form of tautologies and contradictions, because it looks as if one can say that $x = x$ is self-evidently true and $x = y$ self-evidently false. The comparison between $x = x$ and a tautology is of course better than that between $x = y$ and a contradiction, because all correct (and "significant") equations of mathematics are actually of the form $x = y$. We might call $x = x$ a degenerate equation (Ramsey quite correctly called tautologies and contradictions degenerate propositions) and indeed a correct degenerate equation (the limiting case of an equation). For we use expressions of the form $x = x$ like correct

equations, and when we do so we are fully conscious that we are dealing with degenerate equations. In geometrical proofs there are propositions in the same case, such as "the angle α is equal to the angle β , the angle γ is equal to itself..."

Page 317

At this point the objection might be made that correct equations of the form $x = y$ must be tautologies, and incorrect ones contradictions, because it must be possible to prove a correct equation

Page Break 318

by transforming each side of it until an identity of the form $x = x$ is reached. But although the original equation is shown to be correct by this process, and to that extent the identity $x = x$ is the goal of the transformation, it is not its goal in the sense that the purpose of the transformation is to give the equation its correct form--like bending a crooked object straight; it is not that the equation at long last achieves its perfect form in the identity. So we can't say: a correct equation is *really* an identity. It just *isn't* an identity.

Page Break 319

17

The concept of the application of arithmetic†1 (mathematics)

Page 319

If we say "it must be essential to mathematics that it can be applied" we mean that its *applicability* isn't the kind of thing I mean of a piece of wood when I say "I will be able to find many applications for it".

Page 319

Geometry isn't the science (natural science) of geometric planes, lines and points, as opposed to some other science of gross physical lines, stripes and surfaces and *their* properties. The relation between geometry and propositions of practical life, about stripes, colour boundaries, edges and corners, etc. isn't that the things geometry speaks of, though *ideal* edges and corners, resemble those spoken of in practical propositions; it is the relation between those propositions and their grammar. Applied geometry is the grammar of statements about spatial objects. The relation between what is called a geometrical line and a boundary between two colours isn't like the relation between something fine and something coarse, but like the relation between possibility and actuality. (Think of the notion of possibility as a shadow of actuality.)

Page 319

You can describe a circular surface divided diametrically into 8 congruent parts, but it is senseless to give such a description of an elliptical surface. And that contains all that geometry says in this connexion about circular and elliptical surfaces.

Page 319

(A proposition based on a wrong calculation (such as "he cut a 3-metre board into 4 one metre parts") is nonsensical, and that throws light on what is meant by "making sense" and "meaning something by a proposition".)

Page Break 320

Page 320

What about the proposition "the sum of the angles of a triangle is 180 degrees"? At all events you can't tell by looking at it that it is a proposition of syntax.

Page 320

The proposition "corresponding angles are equal" means that if they don't appear equal when they are measured I will treat the measurement as incorrect; and "the sum of the angles of a triangle is 180 degrees" means that if it doesn't appear to be 180 degrees when they are measured I will assume there has been a mistake in the measurement. So the proposition is a postulate about the method of describing facts, and therefore a proposition of syntax.

Page Break 321

IV ON CARDINAL NUMBERS

18

Kinds of cardinal number

Page 321

What are numbers?--What numerals signify; an investigation of what they signify is an investigation of the grammar of numerals.

Page 321

What we are looking for is not a definition of the concept of number, but an exposition of the grammar of the word "number" and of the numerals.

Page 321

The reason why there are infinitely many cardinal numbers, is that *we* construct this infinite system and call it the system of cardinal numbers. There is also a number system "1, 2, 3, 4, 5, many" and even a system "1, 2, 3, 4, 5". Why shouldn't I call that too a system of cardinal numbers (a finite one)?

Page 321

It is clear that the axiom of infinity is not what Russell took it for; it is neither a proposition of logic, nor--as it stands--a proposition of physics. Perhaps the calculus to which it belongs, transplanted into quite different surroundings (with a quite different "interpretation"), might somewhere find a practical application; I do not know.

Page 321

One might say of logical concepts (e.g. of the, or a, concept of infinity) that their essence proves their existence.

Page 321

(Frege would still have said: "perhaps there are people who have not got beyond the first five in their acquaintance with the series of cardinal numbers (and see the rest of the series only in an indeterminate form or something of the kind), but this series exists independently of us". Does chess exist independently of us, or not?--)

Page 321

Here is a very interesting question about the position of the concept of number in logic: what happens to the concept of

Page Break 322

number if a society has no numerals, but for counting, calculating, etc. uses *exclusively* an abacus like a Russian abacus?

Page 322

(Nothing would be more interesting than to investigate the arithmetic of such people; it would make one really understand that here there is no distinction between 20 and 21.)

Page 322

Could we also imagine, in contrast with the cardinal numbers, a kind of number consisting of a series like the cardinal numbers without the 5? Certainly; but this kind of number couldn't be used for *any* of the things for which we use the cardinal numbers. The way in which these numbers are missing a five is not like the way in which an apple may have been taken out of a box of apples and can be put back again; it is of their essence to lack a 5; they do not *know* the 5 (in the way that the cardinal numbers do not know the number $\frac{1}{2}$). So these numbers (if you want to call them that) would be used in cases where the cardinal numbers (with the 5) couldn't meaningfully be used.

Page 322

(Doesn't the nonsensicality of the talk of the "basic intuition" show itself here?)

Page 322

When the intuitionists speak of the "basic intuition"--is this a psychological process? If so, how does it come into mathematics? Isn't what they mean only a primitive sign (in Frege's sense); an element of a calculus?

Page 322

Strange as it sounds, it is possible to know the prime numbers--let's say--only up to 7 and thus to have a finite system of prime numbers. And what we call the discovery that there are infinitely many primes is in truth the discovery of a new system with no greater rights than the other.

Page 322

If you close your eyes and see countless glimmering spots of light coming and going, as we might say, it doesn't make sense to speak of a 'number' of simultaneously seen dots. And you can't say "there is always a definite number of spots of light there, we

Page Break 323

just don't know what it is"; that would correspond to a rule applied in a case where you can speak of checking the number.

Page 323

(It makes sense to say: I divide many among many. But the proposition "I couldn't divide the many nuts among the many people" can't mean that it was logically impossible. Also you can't say "in some cases it is possible to divide many among many and in others not"; for in that case I ask: in *which* cases is this possible and in which impossible? And to that no further answer can be given in the many-system.)

Page 323

To say of a part of my visual field that it has no colour is nonsense; and of course it is equally nonsense to say that it has colour (or a colour). On the other hand it makes sense to say it has only *one* colour (is monochrome, or *uniform* in colour) or that it has at least two colours, only two colours, etc.

Page 323

So in the sentence "this square in my visual field has at least two colours" I cannot substitute "one" for "two". Or again: "the square has only one colour" does not mean--on the analogy of $(\exists x).\phi x.\sim(\exists x, y).\phi x.\phi y$ --"the square has one colour but not two colours".

Page 323

I am speaking here of the case in which it is senseless to say "that part of space has no colour". If I am counting the uniformly coloured (monochrome) patches in the square, it does incidentally make sense to say that there aren't any there at all, if the colour of the square is continually changing. In that case of course it also makes sense to say that there are one or more uniformly coloured patches in the square and also that the square has one colour and not two.--But for the moment I am disregarding that use of the sentence "the square has no colour" and am speaking of a system in which it would be called a matter of course that an area of a surface had a colour, a system, therefore, in which strictly speaking there is no such proposition. If you call the proposition self-evident you really mean something that is expressed by a grammatical rule giving the form of propositions about visual space, for

Page Break 324

instance. If you now begin the series of statements giving the number of colours in the square with the proposition "there is one colour in the square", then of course that mustn't be the proposition of grammar about the "colouredness" of space.

Page 324

What do you mean if you say "space is coloured"? (And, a very interesting question: what kind of question is this?) Well, perhaps you look around for confirmation and look at the different colours around you and feel the inclination to say: "wherever I look there is a colour", or "it's all coloured, all as it were painted." Here you are imagining colours in contrast to a kind of colourlessness, which on closer inspection turns into a colour itself. Incidentally, when you look around for confirmation you look first and foremost at static and monochromatic parts of space, rather than at unstable unclearly coloured parts (flowing water, shadows, etc.) If you then have to admit that you call just everything that you see colour, what you want to say is that being coloured is a property of space in itself, not of the parts of space. But that comes to the same as saying of chess that it is chess; and at best it can't amount to more than a description of the game. So what we must do is describe spatial propositions; but we can't justify them, as if we had to bring them into agreement with an independent reality.

Page 324

In order to confirm the proposition "the visual field is coloured" one looks round and says "that there is black, and black is a colour; that is white, and white is a colour", etc. And one regards "black is a colour" as like "iron is a metal" (or perhaps better, "gypsum is a sulphur compound").

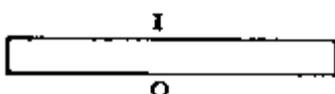

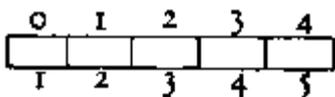

Page 324

If I make it senseless to say that a part of the visual field has a colour, then asking for the analysis of a statement assigning the number of colours in a part of the visual space becomes very like asking for the analysis of a statement of the number of parts of a rectangle that I divide up into parts by lines.

Page 324

Here too I can regard it as senseless to say that the rectangle "consists of no parts". Hence, one cannot say that it consists of one or more parts, or that it has at least *one* part. Imagine the special case of a rectangle divided by parallel lines. It doesn't matter that this is a very special case, since we don't regard a game as less remarkable just because it has only a very limited application.

Page Break 325

Here I can if I want count the parts in the usual manner, and then it is meaningless to say there are 0 parts. But I could also imagine a way of counting which so to say regards the first part as a matter of course and doesn't count it or counts it as 0, and counts only the parts which are added to this by division. Again, one could imagine a custom according to which, say, soldiers in rank and file were always counted by giving the number of soldiers in a line over and above the first soldier (perhaps because we wanted the number of possible combinations of the fugleman with another soldier of the rank.). But a custom might also exist of always giving the number of soldiers as 1 greater than the real one. Perhaps this happened originally in order to deceive a particular officer about the real number, and later came into general use as a way of counting soldiers. (The academic quarter).†1 The number of different colours on a surface might also be given by the number of their possible combinations in pairs and in that case the only numbers that would count would be numbers of the form $n/2(n - 1)$; it would be as senseless then to talk of the 2 or 4 colours of a surface as it now is to talk of the $\sqrt{2}$ or i colours. I want to say that it is not the case that the cardinal numbers are essentially primary and what we might call the combination numbers--1, 2, 6, 10 etc.--are secondary. We might construct an arithmetic of the combination numbers and it would be as self-contained as the arithmetic of the cardinal numbers. But equally of course there might be an arithmetic of the even numbers or of the numbers 1, 3, 4, 5, 6, 7... Of course the decimal system is ill-adapted for the writing of these kinds of number.

Page 325

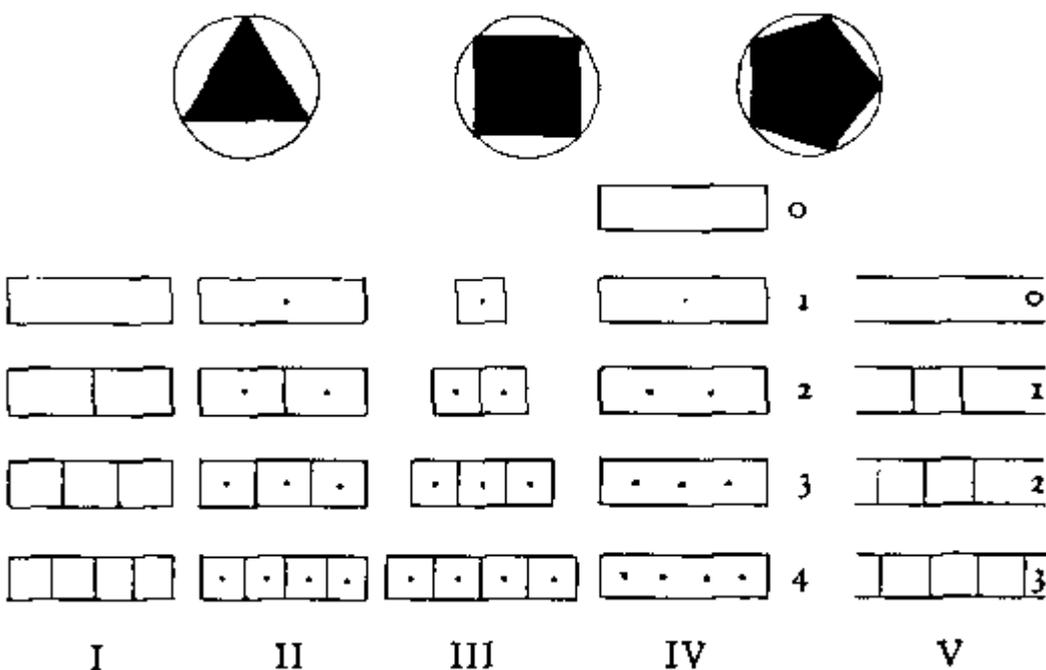

Imagine a calculating machine that calculates not with beads but with colours on a strip of paper. Just as we now use our fingers, or the beads on an abacus, to count the colours on a strip

Page Break 326

so then we would use the colours on a strip to count the beads on a bar or the fingers on our hand. But how would this colour-calculating machine have to be made in order to work? We would need a sign for there being no bead on the bar. We must imagine the abacus as a practical tool and as an instrument in language. Just as we can now represent a number like 5 by the five fingers of a hand (imagine a gesture language) so we would then represent it by a strip with five colours. But I need a sign for the 0, otherwise I do not have the necessary multiplicity. Well, I can either stipulate that a black surface is to denote the 0 (this is of course arbitrary and a monochromatic red surface would do just as well): or that any one-coloured surface is to denote zero, a two-coloured surface 1, etc. It is immaterial which method of denotation I choose. Here we see how the multiplicity of the beads is projected onto the multiplicity of the colours on a surface.

Page 326

It makes no sense to speak of a black two-sided figure in a white circle; this is analogous to its being senseless to say that the rectangle consists of 0 parts (no part). Here we have something like a lower limit of counting before we reach the number one.

Page Break 327

Is counting parts in I the same as counting points in IV? What makes the difference? We may regard counting the parts in I as counting rectangles; but in that case one can also say: "in this row there is *no* rectangle"; and then one isn't counting *parts*. We are disturbed both by the analogy between counting the points and counting the parts, and by the breakdown of the analogy.

There is something odd in counting the undivided surface as "one"; on the other hand we find no difficulty in seeing the surface after a single division as a picture of 2. Here we would much prefer to count "0, 2, 3", etc. And this corresponds to the series of propositions "the rectangle is undivided", "the rectangle is divided into 2 parts", etc.

If it's a question of different colours, you can imagine a way of thinking in which you don't say that here we have two colours, but that here we have a distinction between colours; a style of thought which does not see 3 at all in red, green and yellow; which does indeed recognise as a series a series like: red; blue, green; yellow, black, white; etc., but doesn't connect it with the series |; ||; |||; etc., or not in such a way as to correlate | with the term red.

From the point of view from which it is 'odd' to count the undivided surface as one, it is also natural to count the singly divided one as two. That is what one does if one regards it as two rectangles, and that would mean looking at it from the standpoint from which the undivided one might well be counted as one rectangle. But if one regards the first rectangle in I as the undivided surface, then the second appears as a whole with one division (one distinction) and division here does not necessarily mean dividing line. What I am paying attention to is the distinctions, and here there is a series of an increasing number of distinctions. In that case I will count the rectangles in I "0, 1, 2, etc."

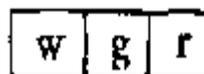

This is all right where the colours on a strip border on each other, as in the schema

But it is different if the arrangement is

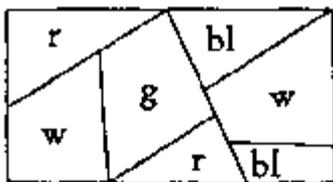

. Of course

I might also correlate each of these two schemata with the schema

and correlate schemata like

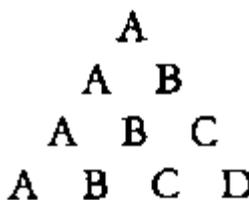

with the schema

, etc. And that way of thinking though

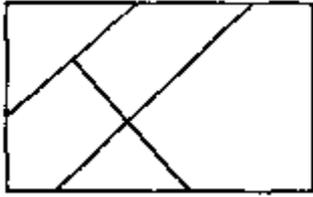

certainly unnatural is perfectly correct.

The most natural thing is to conceive the series of schemata as etc. And here we may denote the first schema by '0', the second by '1', but the third say with '3', if we think of all possible distinctions, and the fourth by '6' Or we may call the third schema '2' (if we are concerned simply with an arrangement) and the fourth '3'.

We can describe the way a rectangle is divided by saying: it is divided into five parts, or: 4 parts have been

cut off it, or: its division-schema is ABCDE, or: you can reach every part by crossing four boundaries or: the rectangle is divided (i.e. into 2 parts), one part is divided again, and both parts of *this* part divided, etc. I want to show that there isn't only *one* method of describing the way it is divided.

Page Break 329

Page 329

But perhaps we might refrain altogether from using a number to denote the distinction and keep solely to the schemata A, AB, ABC, etc.; or we might describe it like this: 1, 12, 123 etc., or, what comes to the same, 0, 01, 012 etc.

Page 329

We may very well call these too numerals.

Page 329

The schemata A, AB, ABC etc., |, ||, |||, etc.;  ,  ,  ,  etc.; 0, 1, 2, 3, etc.; 1, 2, 3, etc.; 1, 12, 121323, etc., etc., are all equally fundamental.

Page 329

We are surprised that the number-schema by which we count soldiers in a barracks isn't supposed also to hold for the parts of a rectangle. But the schema for the soldiers in the barracks is  ,  ,  , etc., the one for the parts of the rectangle is  ,  ,  , etc. Neither is primary in comparison with the other.

Page 329

I can compare the series of division-schemata with the series 1, 2, 3, etc. as well as with the series 0, 1, 2, 3, etc.

Page 329

If I count the parts, then there is no 0 in my number series because the series

A
A B
A B C etc. begins with *one* letter whereas the series  ,  ,  , etc. does not begin with *one* dot. On the other hand, I can represent any fact about the division by this series too, only in that case "I'm not counting the parts".

Page 329

A way of expressing the problem which, though incorrect, is natural is: why can one say "there are 2 colours on this surface" but not "there is *one* colour on this surface?" Or: how must I express the grammatical rule so that it is obvious and so that I'm not any longer tempted to talk nonsense? Where is the false thought, the

Page Break 330

false analogy by which I am misled into misusing language? How must I set out the grammar so that this temptation ceases? I think that setting it out by means of the series

A
A B
A B C
and so on **and** 

and so on

removes the unclarity.

Page 330

What matters is whether in order to count 1 use a number series that begins with 0 or one that begins with 1.

It is the same if I am counting the lengths of sticks or the size of hats.

If I counted with strokes, I might write them thus $|, \vee, \nabla, \swarrow$, in order to show that what matters is the *distinction* between the directions and that a simple stroke corresponds to 0 (i.e. is the beginning).

Here incidentally there is a certain difficulty about the numerals (1), ((1) + 1), etc.: beyond a certain length we cannot distinguish them any further without counting the strokes, and so without translating the signs into different ones. "||||||" and "||||||" cannot be distinguished in the same sense as 10 and 11, and so they aren't in the same sense distinct signs. The same thing could also happen incidentally in the decimal system (think of the numbers 111111111 and 1111111111), and that is not without significance.

Imagine someone giving us a sum to do in a stroke-notation, say ||||| + |||||, and, while we are calculating, amusing himself by removing and adding strokes without our noticing. He would keep on saying: "but the sum isn't right", and we would keep going through it again, fooled every time.--Indeed, strictly speaking, we wouldn't have any concept of a criterion for the correctness of the calculation.

Here one might raise questions like: is it only *very probable* that $464 + 272 = 736$? And in that case isn't $2 + 3 = 5$ also only very probable? And where is the objective truth which this probability approaches? That is, how do we get a concept of $2 + 3$'s really *being* a certain number, apart from what it *seems* to us to be?

For if it were asked: what is the criterion in the stroke-notation for our having the same numeral in front of us twice?--the answer might be: "if it looks the same both times" or "if it contains the same number of lines both times". Or should it be: if a one-one correlation etc. is possible?

How can I know that ||||| and ||||| are the *same* sign? After all it is not enough that they look *alike*. For having roughly the same gestalt can't be what is to constitute the identity of the signs, but just their being the same in number.

(The problem of the distinction between $1 + 1 + 1 + 1 + 1 + 1 + 1$ and $1 + 1 + 1 + 1 + 1 + 1 + 1$ is much more fundamental than appears at first sight. It is a matter of the distinction between physical and visual number.)

$$19$$

$$2 + 2 = 4$$

A cardinal number is an internal property of a list. Are numbers essentially concerned with concepts? I believe this amounts to asking whether it makes sense to ascribe a number to objects that haven't been brought under a concept. Does it, for example, make sense to say "a, b and c are three objects"?--Admittedly we have a feeling: why talk about concepts, the number of course depends only on the *extension* of the concept, and once that has been determined the concept may drop out of the picture. The concept is only a method for determining an extension, but the extension is autonomous and, in its essence, independent of the concept; for it's quite immaterial which concept we have used to determine the extension. That is the argument for the extensional viewpoint. The immediate objection to it is: if a concept is really only an expedient for aiming at an extension, then there is no place for concepts in arithmetic; in that case we must simply divorce a class completely from the concept which happens to be associated with it. But if it isn't like that, then an extension independent of the concept is just a chimaera, and in that case it's better not to speak of it at all, but only of the concept.

The sign for the extension of a concept is a list. We might say, as an approximation, that a number is an external property of a concept and an internal property of its extension (the list of objects that fall under it). A number is a schema for the extension of a concept. That is, as Frege said, a statement of number is a statement about a concept (a predicate). It's not about the extension of a concept, i.e. a list that may be something like the extension of a concept. But a number-statement about a concept has a similarity to a proposition saying that a determinate list is the extension of the concept. I use such a list when I say "a, b, c, d, fall under the concept $F(x)$ ": "a, b, c, d," is the list. Of course this proposition

says the same as Fa.Fb.Fc.Fd; but the use of the list in writing the proposition shows its relationship to " $(\exists x, y, z, u). Fx.Fy.Fz.Fu$ " which we can abbreviate as " $(\exists |||x).F(x)$."

What arithmetic is concerned with is the schema $|||$.--But does arithmetic talk about the lines that I draw with pencil on paper?--Arithmetic doesn't talk about the lines, it *operates* with them.

A statement of number doesn't always contain a generalization or indeterminacy: "The line AB is divided into 2 (3, 4, etc.) equal parts."

If you want to know what $2 + 2 = 4$ means, you have to ask how we work it out. That means that we consider the process of calculation as the essential thing; and that's how we look at the matter in ordinary life, at least as far as concerns the numbers that we have to work out. We mustn't feel ashamed of regarding numbers and sums in the same way as the everyday arithmetic of every trader. In everyday life we don't work out $2 + 2 = 4$ or any of the rules of the multiplication table; we take them for granted like axioms and *use them* to calculate. But of course we could work out $2 + 2 = 4$ and children in fact do so by counting off. Given the sequence of numbers 1 2 3 4 5 the

1 2 1 2

calculation is 1 2 3 4

Abbreviative Definitions:

$$\begin{aligned}
 (\exists x). \phi x : \sim (\exists x, y). \phi x. \phi y & \stackrel{\text{Def}}{=} .(\epsilon x). \phi x \\
 (\exists x, y). \phi x. \phi y : \sim (\exists x, y, z). \phi x. \phi y. \phi z & \stackrel{\text{Def}}{=} .(\epsilon x, y). \phi x. \phi y, \text{ etc.} \\
 (\epsilon x). \phi x & \stackrel{\text{Def}}{=} .(\epsilon |x). \phi x \\
 (\epsilon x, y). \phi x. \phi y & \stackrel{\text{Def}}{=} .(\epsilon ||x). \phi x. \stackrel{\text{Def}}{=} .(\epsilon 2x). \phi x, \text{ etc.}
 \end{aligned}$$

It can be shewn that

$$(\epsilon ||x). \phi x. (\epsilon |||x). (\psi x). \underbrace{\sim (\exists x). \phi x. \psi x}_{\text{Ind.}} \supset .(\epsilon ||||x). \phi x \vee \psi x$$

is a tautology.

Does that prove the arithmetical proposition $2 + 3 = 5$? Of course not. It does not even show that $(\epsilon ||x). \phi x. (\epsilon |||x). \psi x. \text{Ind.} \supset .(\epsilon || + |||x). \phi x \vee \psi x$ is tautologous, because nothing was said in our definitions about a sum $(|| + |||)$. (I will write the tautology in the abbreviated form " $\epsilon ||. \epsilon |||. \supset . \epsilon ||||$ ".) Suppose the question is, given a left hand side, to find what number of lines to the right of " \supset " makes the whole a tautology. We can find the number, we can indeed discover that in the case above it is $|| + |||$; but we can equally well discover that it is $| + ||||$ or $| + ||| + |$, for it is all of these. We can also find an inductive proof that the algebraic expression

$$\epsilon n. \epsilon m. \supset . \epsilon n + m$$

is tautologous. Then I have a right to regard a proposition like

$$\epsilon 17. \epsilon 28. \supset . \epsilon (17 + 28)$$

as a tautology. But does that give us the equation $17 + 28 = 45$? Certainly not. I still have to work it out. In accordance with this general rule, it also makes sense to write $\epsilon 2. \epsilon 3. \supset . \epsilon 5$ as a tautology if, as it were, I don't yet know what $2 + 3$ yields; for $2 + 3$ only has sense in so far as it has still to be worked out.

Hence the equation $|| + ||| = ||||$ only has a point if the sign "||||" can be recognised in the same way as the sign "5", that is, independently of the equation.

The difference between my point of view and that of contemporary writers on the foundations of arithmetic is that I am not obliged to despise particular calculi like the decimal system. For me one calculus is as good as another. To look down on a particular calculus is like wanting to play chess without real pieces, because playing with pieces is too particularized and not abstract enough. If the pieces really *don't* matter then one lot is just as good as

another. And if the games are really distinct from each other, then one game is as good, i.e. as interesting, as the other. None of them is more sublime than any other.

Page Break 335

Page 335

Which proof of $\varepsilon||. \varepsilon|||. \supset. \varepsilon||||$ expresses our knowledge that this is a correct logical proposition?

Page 335

Obviously, one that makes use of the fact that one can treat $(\exists x)...$ as a logical sum. We may translate from a symbolism like $\begin{array}{|c|c|} \hline * & * \\ \hline \end{array}$ ("if there is a star in each square, then there are two in the whole rectangle") into the Russellian one. And it isn't as if the tautologies in that notation expressed an idea that is confirmed by the proof after first of all appearing merely plausible; what appears plausible to us is that this expression is a tautology (a law of logic).

Page 335

The series of propositions

$$(\exists x): aRx.xRb$$

$$(\exists x, y): aRx.xRy.yRb$$

$$(\exists x, y, z): aRx.xRy.yRz.zRb, \text{ etc.}$$

may perfectly well be expressed as follows:

Page 335

"There is one term between a and b".

Page 335

"There are two terms between a and b", etc.,

and may be written in some such way as:

$$(\exists 1x).aRxRb, (\exists 2x).aRxRb, \text{ etc.}$$

Page 335

But it is clear that in order to understand this expression we need the explanation above, because otherwise by analogy with $(\exists 2x).\phi x. = .(\exists x, y).\phi x.\phi y$ you might believe that $(\exists 2x).aRxRb$ was equivalent to the expression $(\exists x, y).aRxRb.aRyRb$.

Page 335

Of course I might also write " $(\exists 2x, y).F(x, y)$ " instead of " $(\exists x, y).F(x, y)$ ". But then the question would be: what am I to take " $(\exists 3x, y).F(x, y)$ " as meaning? But here a rule can be given; and indeed we need one that takes us further in the number series as far as we want to go. E.g.:

$$(\exists 3x, y).F(x, y). = .(\exists x, y, z):F(x, y).F(x, z).F(y, z)$$

$$(\exists 4x, y).F(x, y). = .(\exists x, y, z, u):F(x, y).F(x, z)...$$

followed by the combinations of two elements, and so on. But we might also give the following definition:

$$(\exists 3x, y).F(x, y). = .(\exists x, y, z):F(x, y).F(y, x).F(x, z).$$

$$F(z, x).F(y, z).F(x, y), \text{ and so on.}$$

Page Break 336

Page 336

" $(\exists 3 x, y).F(x, y)$ " would perhaps correspond to the proposition in word-language "F(x, y) is satisfied by 3 things"; and that proposition too would need an explanation if it was not to be ambiguous.

Page 336

Am I now to say that in these different cases the sign "3" has different meanings? Isn't it rather that the sign "3" expresses what is common to the different interpretations? Why else would I have chosen it? Certainly, in each of these contexts, the same rules hold for the sign "3". It is replaceable by 2 + 1 as usual and so on. But at all events a proposition on the pattern of $\varepsilon||. \varepsilon|||. \supset. \varepsilon||||$ is no longer a tautology. Two men who live at peace with each other and three other men who live at peace with each other do not make five men who live at peace with each other. But that does not mean that 2 + 3 are no longer 5; it is just that addition cannot be applied in that way. For one might say: 2 men who... and 3 men who..., each of whom lives at peace with each of the first group, = 5 men who...

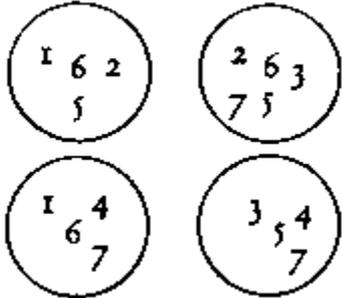

Page 336

In other words, the signs of the form $(\exists 1x, y).F(x, y), (\exists 2x, y). F(x, y)$ etc. have the same multiplicity as the

cardinal numbers, like the signs $(\exists 1x).\phi x$, $(\exists 2x).\phi x$, etc. and also like the signs $(\epsilon 1x).\phi x$, $(\epsilon 2x).\phi x$, etc.

Page 336

"There are only 4 red things, but they don't consist of 2 and 2, as there is no function under which they fall in pairs". That would mean regarding the proposition $2 + 2 = 4$ thus: if you can see 4 circles on a surface, every two of them always have a particular property in common; say a sign inside the circle. (In that case of course every three of the circles too will have to have a sign in common etc.) If I am to make any assumption at all about reality, why not *that*? The 'axiom of reducibility' is essentially the same kind of thing. In this sense one might say that 2 and 2 do always make 4, but 4 doesn't always consist of 2 and 2. (It is only because of the utter vagueness and generality of the axiom of reducibility that we are seduced

Page Break 337

into believing that--if it is a significant sentence at all--it is more than an arbitrary assumption for which there is no ground. For this reason, in this and all similar cases, it is very illuminating to drop this generality, which doesn't make the matter any more mathematical, and in its place to make very specific assumptions.)

Page 337

We feel like saying: 4 does not always have to consist of 2 and 2, but if it does consist of groups it can consist of 2 and 2, or of 3 and 1 etc.; but not of 2 and 1 or 3 and 2, etc. In that way we get everything prepared in case 4 is actually divisible into groups. But in that case arithmetic doesn't have anything to do with the actual division, but only with the possibility of division. The assertion might just as well be the assertion that any two of a group of 4 dots on paper are always joined by a line.

Page 337

Or that around every 2 such groups of 2 dots in the real world there is always a circle drawn.

Page 337

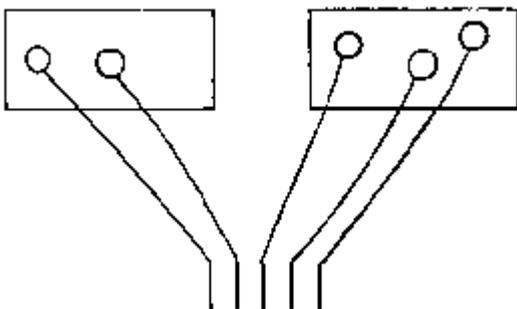

Add to this that a statement like "you can see two black circles in a white rectangle" doesn't have the form $(\exists x, y)$, etc.". For, if I give the circles names, the names refer to the precise location of the circles and I can't say of them that they are either in this rectangle or in the other. I can indeed say "there are 4 circles in both rectangles taken together" but that doesn't mean that I can say of each individual circle that it is in one rectangle or the other. For in the case supposed the sentence "this circle is in this rectangle" is senseless.

Page 337

But what does the proposition "there are 4 circles in the 2 rectangles taken *together*" mean? How do I establish that? By adding the numbers in each? In that case the number of the circles in the two rectangles *means* the result of the addition of the two numbers.--Or is it something like the result of taking a count through both rectangles? Or the number of lines I get if I correlate a line to a circle no matter whether it is in this rectangle *or* in the

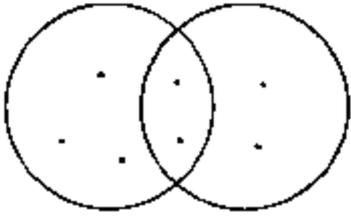

Page Break 338

other? If "this circle" is individuated by its position, we can say "every line is correlated either to a circle in this rectangle or to a circle in the other rectangle" but not "this circle is either in this

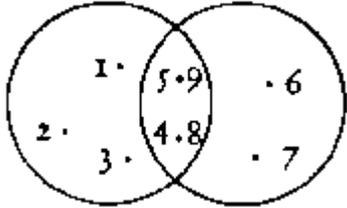

rectangle or in the other". *This* can only be *here* if "this" and "here" do not mean the same. By contrast *this* line can be correlated to a circle in this rectangle because it remains *this* line, even if it is correlated to a circle in the other

rectangle.

Page 338

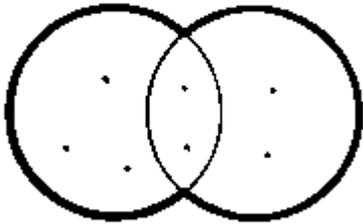

In these two circles together are there 9 dots or 7? As one normally understands the question, 7. But must I understand it so? Why shouldn't I count twice the points that are common to both circles?

Page 338

It is a different matter if we ask "how many dots are within the black lines?" For here I can say: in the sense in which there are 5 and 4 in the circles, there are 7.

Page Break 339

Page 339

Now we might say: by the sum of 4 and 5 I mean the number of the objects which fall under the concept $\phi x \vee \psi x$, if it is the case that $(\exists 4x) \uparrow 1. \phi x. (\exists 5x). \psi x$. Ind. That doesn't mean that the sum of 4 and 5 may only be used in the context of propositions like $(\exists 4x). \phi x$; it means: if you want to construct the sum of n and m, insert the numbers on the left hand side of " \supset " in the form $(\exists nx). \phi x. (\exists mx). \psi x$, etc., and the sum of m and n will be the number which has to go on the right hand side in order to make the whole proposition a tautology. So that is a method of addition--a very long-winded one.

Page 339

Compare: "Hydrogen and oxygen yield water", "2 dots and 3 dots yield 5 dots".

Page 339

So do e.g. 2 dots in my visual field, that I "see as 4" and not "as 2 and 2", consist of 2 and 2? Well, what does that mean? Is it asking whether in some way they are divided into groups of 2 dots each? Of course not (for in that case they would presumably have had to be divided in all other conceivable ways as well). Does it mean that they *can* be divided into groups of 2 and 2, i.e. that it *makes sense* to speak of such groups in the four?--At any rate it does correspond to the sentence $2 + 2 = 4$ that I can't say that the group of 4 dots I saw consisted of separate groups of 2 and 3. Everyone will say: that's impossible, *because* $3 + 2 = 5$. (And "impossible" here means "nonsensical".)

Page 339

"Do 4 dots consist of 2 and 2?" may be a question about a physical or visual fact; for it isn't the question in arithmetic. The

Page Break 340

arithmetical question, however, certainly could be put in the form: "Can a group of 4 dots consist of separate groups of 2?"

Page 340

"Suppose that I used to believe that there wasn't anything at all except one function and the 4 objects that satisfy it. Later I realise that it is satisfied by a fifth thing too: does this make the sign '4' become senseless?"--Well, if there is no 4 in the *calculus* then '4' is senseless.

Page 340

If you say it would be possible when adding to make use of the tautology $(\exists 2x).\phi x.(\exists 3x).\psi x.Ind. \supset.(\exists 5x).\phi x \vee \psi x... A)$ this is how it would have to be understood: first it is possible to establish according to certain rules that $(\exists x).\phi x. (\exists x).\psi x.Ind.. \supset.(\exists x, y):\phi x \vee \psi x.\phi y \vee \psi y.$ is tautological. $(\exists x).\phi x$ is an abbreviation for $(\exists x).\phi x. \sim(\exists x, y).\phi x.\phi y.$ I will abbreviate further tautologies like A thus: $(E).(E).\supset.(E)$

Page 340

Therefore

$(\exists x).(E x). \supset.(\exists x, y).(E x, y).(E x). \supset.(\exists x, y, z).$

and other tautologies follow from the rules. I write "and other tautologies" and not "and so on ad inf." since one doesn't yet have to use that concept.

Page 340

†1 When the numbers were written out in the decimal system there were rules, namely the addition rules for every pair of numbers from 0 to 9, and, used appropriately, these sufficed for the addition of all numbers. Now which rule corresponds to these elementary

Page Break 341

rules? It is obvious that in a calculation like σ we don't have to keep as many rules in mind as in $17 + 28$. Indeed we need only *one* general rule. We don't need any rules like $3 + 2$; on the contrary, we now seem to be able to deduce, or work out, how many $3 + 2$ makes.

Page 341

We are given the sum $2 + 3 = ?$ and we write

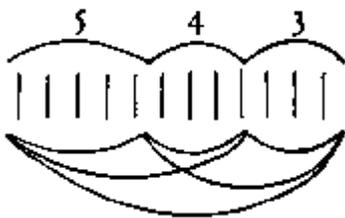

1, 2, 3, 4, 5, 6, 7
1, 2; 1, 2, 3

Page 341

That is in fact how children calculate when they "count off". (And that calculus must be as good as any other.)

Page 341

It is clear incidentally that the problem whether $5 + (4 + 3) = (5 + 4) + 3$ can be solved in *this* way:

for this construction has precisely the same multiplicity as every other proof of that proposition.

A	B	C	D	E	F	G	H	I	J	K	L	MNO
A	B	C	D	E,	A	B	C	D				
A								I,	A	B	C	
A					A	B	C	D,	A	B	C	
A					A		G					
A				E,	A		G					
A							L					

Page 341

If I name each number after its last letter, that is a proof that $(E + D) + C = E + (D + C) = L$

Page 341

This is a good form of proof, because it shows clearly that the result is really worked out and because from it you can read off the general proof as well.

Page 341

It may sound odd, but it is good advice at this point: don't do philosophy here, do mathematics.

Page Break 342

Our calculus doesn't at all need to be acquainted with the construction of a series '(E x)', '(E x, y)', '(E x, y, z)' etc.; we can simply introduce two or three such signs without the "etc.". We can then introduce a calculus with a finite series of signs by laying down a sequence of certain signs, say the letters of the alphabet, and writing:

(E a).(E a). \supset .(E a, b)
 (E a, b).(E a). \supset .(E a, b, c)
 (E a, b).(E a, b). \supset .(E a, b, c, d)
 etc. up to z.

The right hand side (the side to the right of " \supset ") can then be found from the left hand side by a calculus like:

a b c d e f . . . z
 a b - - -
 - - a b c

B)

a b c d e

This calculus could be derived from the rules for the construction of tautologies as a simplification.--If I presuppose this law for constructing a fragment of the series out of two others, I can then introduce as a designation of that fragment the expression "sum of the two others", and thus give the definition:

a + a $\stackrel{\text{Def}}{=}$ ab
 a + ab $\stackrel{\text{Def}}{=}$ abc

and so on up to z.

If the rules for the calculus B had been explained by examples, we could regard those definitions too as particular cases of a general rule and then set problems like "abc + ab =?". It is now tempting to confuse the tautology

α) (E a, b). (E a, b). \supset . (E a, b, c, d)

with the equation

β) ab + ab = abcd

But the latter is a replacement rule, the former isn't a rule but just a tautology. The sign " \supset " in α in no way corresponds to the "=" in β .

We forget that the sign " \supset " in α doesn't say that the two signs to the left and right of it yield a tautology.

On the other hand we might construct a calculus in which the equation $\xi + \eta = \eta$ was obtained as a transformation of the equation

γ) (E ξ).(E η). \supset .(E ζ) = Taut.

So that I as it were get $\zeta = \xi + \eta$ if I work out ζ from the equation γ .

In these discussions, how does the concept of sum make its entry?--There is no mention of summation in the original calculus that lays down that the form

δ) (E ξ).(E η). \supset (E ζ)

is tautologous where $\xi = xy$, $y = x$ and $\zeta = xyz$.--Later we introduce into the calculus a number system (say the system a, b, c, d,... z), and finally we define the sum of two numbers as the number that solves the equation γ .

If we wrote "(E x).(E x). \supset .(E x, y)" instead of "(E x). (E x). \supset . (E x + x)" it would make no sense; unless the

notation already went, not

Page 343

ι) "(E x), etc.", "(E x, y) etc.", "(E x, y, z), etc."

but

Page 343

κ) "(E x), etc.", "(E x + x) etc.", "(E x + x + x), etc."

For why should we suddenly write

"(E x, y).(E x). ⊃.(E xy + x)" instead of "(E x, y).(E x). ⊃.(E x, y, z)"?

That would just confuse the notation.--Then we say: it will greatly simplify the writing of the tautologies if we can write in the right bracket simply the expressions in the two left brackets. But so far that notation hasn't been explained: I don't know what (E xy + x) means, or that (E xy + x) = (E x, y, z).

Page 343

But if the notation already went "(E x)", "(E x + x)", "(E x + x + x)" that would only give a sense to the expression "(E x + x + x + x + x)" and not to (E (x + x) + (x + x)).

Page 343

The notation κ is in the same case as ι. A quick way of calculating whether you get a tautology of the form δ is to draw connecting lines, thus

Page Break 344

$(E x, y) . (E x, y) . \supset . (E x, y, z, u)$

and analogously

$(E x + x) . (E x + x) . \supset . (E x \cdot x \cdot | x \cdot | x)$

Page 344

The connecting lines only correspond to the rule which we have to give in any case for checking the tautology. There is still no mention of addition; that doesn't come in until I decide--e.g.--to write "xy + yx" instead of "x, y, z, u" and adjoin a calculus with rules that allow the derivation of the replacement rule "xy + yx = xyzu".

Again, addition doesn't come in when I write in the notation κ "(E x).(E x). ⊃.(E x + x)"; it only comes in when I distinguish between "x + x" and "(x) + (x)" and write (x) + (x) = (x + x)

Page 344

I can define "the sum of ξ and η" "(ξ + η)" as the number (or "the expression" if we are afraid to use the word "number")--I can define "ξ + η" as the number ζ that makes the expression δ tautologous; but we can also define "ξ + η" (independently of the calculus of tautologies) by the calculus B and then *derive* the equation (E ξ).(E η). ⊃. (E ξ + η) = Taut.

Page 344

A question that suggests itself is this: must we introduce the cardinal numbers in connection with the notation (∃x, y,...).φx.φy...? Is the calculus of the cardinal numbers somehow bound up with the calculus of the signs "(∃x, y,...).φx.φy...? Is that kind of calculus perhaps in the nature of things the only application of the cardinal numbers? So far as concerns the "application of the cardinal numbers in the grammar", we can refer to what we said about the concept of the application of a calculus. We might put our question in this way too: in the propositions of our language--if we imagine them translated into Russell's notation--do the cardinal numbers always occur after the sign "∃"? This question

Page Break 345

is closely connected with another: Is a numeral always used in language as a characterization of a concept--a function? The answer to that is that our language does always use the numerals as attributes of concept-words--but that these concept-words belong to different grammatical systems that are so totally distinct from each other (as you see from the fact that some of them have meaning in contexts in which others are senseless), that a norm making them all concept-words is an uninteresting one. But the notation "(∃x, y,...) etc." is just such a norm. It is a straight translation of a norm of our word-language, the expression "there is...", which is a form of expression into which countless grammatical forms are squeezed.

Moreover there is another sense of numeral in which numerals are not connected with " \exists ": that is, in so far as " $(\exists 3)_x \dots$ " is not contained in " $(\exists 2 + 3)_x \dots$ ".

If we disregard functions containing "=" ($x = a. \vee .x = b$, etc.), then on Russell's theory $5 = 1$ if there are no functions that are satisfied by only *one* argument, or by only 5 arguments. Of course at first this proposition seems nonsensical; for in that case how can one sensibly say that there are no such functions? Russell would have to say that the statement that there are five-functions and the statement that these are one-functions can only be separated if we have in our symbolism a five-class and a one-class. Perhaps he could say that his view is correct because without the paradigm of the class 5 in the symbolism, I can't say at all that a function is satisfied by five arguments. That is to say, from the existence of the sentence " $(\exists \phi: (\exists 1 x). \phi x$ " its truth already follows.--So you seem to be able to say: look at this sentence, and you will see that it is true. And in a sense irrelevant for our purposes that is indeed possible: think of the wall of a room on which is written in red "in this room there is something red".--

This problem is connected with the fact that in an ostensive definition I do not state anything about the paradigm (sample); I only use it to make a statement. It belongs to the symbolism and is not one of the objects to which I apply the symbolism.

For instance, suppose that "1 foot" were defined as the length of a particular rod in my room, so that instead of saying "this door is 6 ft high" I would say "this door is six times as high as *this* length" (pointing to the unit rod). In that case we couldn't say things like "the proposition 'there is an object whose length is 1 ft' proves itself, because I couldn't express the proposition at all if there were no object of that length". (That is, if I introduced the sign "*this* length" instead of "1 foot", then the statement that the unit rod is 1 foot long would mean "this rod has this length" (where I point both times to the same rod).) Similarly one cannot say of a group of strokes serving as a paradigm of 3, that it consists of 3 strokes.

"If the proposition isn't true, then the proposition doesn't exist" means: "if the proposition doesn't exist, then it doesn't exist". And one proposition can never describe the paradigm in another, unless it ceases to be a paradigm. If the length of the unit rod can be described by assigning it the length "1 foot", then it isn't the paradigm of the unit of length; if it were, every statement of length would have to be made by means of it.

If we can give any sense at all to a proposition of the form " $\sim(\exists \phi): (\exists x). \phi x$ " it must be a proposition like: "there is no circle on this surface containing only *one* black speck" (I mean: it must have that sort of *determined* sense, and not remain vague as it did in Russellian logic and in my logic in the *Tractatus*).

If it follows from the propositions

$$\rho) \sim(\exists \phi): (\exists x). \phi x$$

$$\text{and } \sigma) \sim(\exists \phi): (\exists x, y). \phi x. \phi y$$

that $1 = 2$, then here "1" and "2" don't mean what we commonly

mean by them, because in word-language the propositions ρ and σ would be "there is no function that is satisfied by only one thing" and "there is no function that is satisfied by only two things." And according to the rules of our language these are propositions with different senses.

One is tempted to say: "In order to express ' $(\exists x, y). \phi x. \phi y$ ' we need 2 signs 'x' and 'y'." But that has no meaning. What we *need* for it, is, perhaps, pen and paper; and the proposition means no more than "to express 'p' we need 'p'."

If we ask: but what then does " $5 + 7 = 12$ " mean--what kind of significance or point is left for this expression after the elimination of the tautologies, etc. from the arithmetical calculus?--the answer is: this equation is a replacement rule which is based on certain general replacement rules, the rules of addition. The content of $5 + 7 = 12$ (supposing someone didn't know it) is precisely what children find difficult when they are learning this proposition in arithmetic lessons.

No investigation of concepts, only insight into the number-calculus can tell us that $3 + 2 = 5$. That is what makes us rebel against the idea that

" $(\exists x)\phi x \cdot (\exists x)\psi x \text{ Ind.} : \supset (\exists x)\phi x \vee \psi x$ "†1

could be the proposition $3 + 2 = 5$. For what enables us to tell that this expression is a tautology cannot itself be the result of an examination of concepts, but must be recognizable from the calculus. For the grammar is a calculus. That is, nothing of what the tautology calculus contains apart from the number calculus serves to justify it and if it is number we are interested in the rest is mere decoration.

Children learn in school that $2 \times 2 = 4$, but not that $2 = 2$.

Statements of number within mathematics

What distinguishes a statement of number about a concept from one about a variable? The first is a proposition about the concept, the second a grammatical rule concerning the variable.

But can't I specify a variable by saying that its values are to be all objects satisfying a certain function? In that way I do not indeed *specify* the variable unless I *know* which objects satisfy the function, that is, if these objects are given me in another way (say by a list); and then giving the function becomes superfluous. If we do not know whether an object satisfies the function, then we do not know whether it is to be a value of the variable, and the grammar of the variable is in that case simply not expressed in this respect.

Statements of number *in* mathematics (e.g. "The equation $x^2 = 1$ has 2 roots") are therefore quite a different kind of thing from statements of number outside mathematics ("There are 2 apples on the table").

If we say that A B admits of 2 permutations, it sounds as if we had made a *general* assertion, analogous to "There are 2 men in the room" in which nothing further is said or need be known about the men. But this isn't so in the A B case. I cannot give a more general description of A B, B A and so the proposition that no permutations are possible cannot say less than that the permutations A B, B A are possible. To say that 6 permutations of 3 elements are possible cannot say less, i.e. anything more general, than is shown by the schema:

A B C
A C B
B A C
B C A
C A B
C B A

For it's *impossible* to know the number of possible permutations without knowing which they are. And if this weren't so, the theory of combinations wouldn't be capable of arriving at its general formulae. The law which we see in the formulation of the permutations is represented by the equation $p = n!$ In the same sense, I believe, as that in which a circle is given by its equation.--Of course I can correlate the number 2 with the permutations A B, B A just as I can 6 with the complete set of permutations of A, B, C, but that does not give me the theorem of combination theory.--What I see in A B, B A is an internal relation which therefore cannot be described. That is, *what* cannot be described is that which makes this class of permutations complete.--I can only count what is actually there, not possibilities. But I can e.g. work out how many rows a man must write if in each row he puts a permutation of 3 elements and goes on until he cannot go any further without repetition. And this means, he needs 6 rows to write down the permutations A B C, A C B, etc., since these just are "the permutations of A, B, C". But it makes no sense to say that these are all permutations of A B C.

We could imagine a combination computer exactly like the Russian abacus.

It is clear that there is a mathematical question: "How many permutations of--say--4 elements are there?", a question of precisely the same kind as "What is 25×18 ?". For in both cases there is a general method of solution.

Page 349

But still it is only with respect to this method that this question exists.

Page 349

The proposition that there are 6 permutations of 3 elements is identical with the permutation schema and thus there isn't here a proposition "There are 7 permutations of 3 elements", for no such schema corresponds to it.

Page Break 350

Page 350

You could also conceive the number 6 in this case as another kind of number, the permutation-number of A, B, C. Permutation as another kind of counting.

Page 350

If you want to know what a proposition means, you can always ask "How do I know that?" Do I know that there are 6 permutations of 3 elements in the same way in which I know that there are 6 people in this room? No. Therefore the first proposition is of a different *kind* from the second.

Page 350

You may also say that the proposition "There are 6 permutations of 3 elements" is related to the proposition "There are 6 people in this room" in precisely the same way as is " $3 + 3 = 6$ ", which you could also cast in the form "There are 6 units in $3 + 3$ ". And just as in the one case I can count the rows in the permutation schema, so in the other I can count the strokes in

|||
|||

Just as I can prove that $4 \times 3 = 12$ by means of the schema

○ ○ ○
○ ○ ○
○ ○ ○
○ ○ ○

I can also prove $3! = 6$ by means of the permutation schema.

Page 350

The proposition "the relation R links two objects", if it is to mean the same as "R is a two-place relation", is a proposition of grammar.

Page Break 351

Page 351

How should we regard the propositions "these hats are of the same size", or "these rods have the same length" or "these patches have the same colour"? Should we write them in the form " $(\exists L).La. Lb$ "? But if that is intended in the usual way, and so is used with the usual rules, it would mean that it made sense to write " $(\exists L).La$ ", i.e. "the patch has a colour", "the rod has a length". Of course I can write " $(\exists L).La.Lb$ " for "a and b have the same length" provided that I know and bear in mind that " $(\exists L).La$ " is senseless; but then the notation becomes misleading and confusing ("to have a length", "to have a father").--What we have here is something that we often express in ordinary language as follows: "If a has the length L, so does b"; but here the sentence "a has the length L" has no sense, or at least not as a statement about a; the proposition should be reworded "if we call the length of a 'L', then the length of b is L" and 'L' here is essentially a variable. The proposition incidentally has the form of an example, of a proposition that could serve as an example for the general sentence; we might go on: "for example, if the length of a is 5 metres, then the length of b is 5 metres, etc."--Saying "the rods a and b have the same length" says nothing about the length of each rod; for it doesn't even say "that each of the two has a length". So it is quite unlike "A and B have the same father" and "the name of the father of A and B is 'N'", where I simply substitute the proper name for the general description. It is not that there is a certain length of which we are at first only told that a and b both possess it, and of which '5m' is the name. If the lengths are lengths in the visual field we can say the two lengths are the same, without in general being able to "name" them with a number.--The written form of the proposition "if L is the length of a, the length of b too is L" is derived from the form of an example. And we might express the general proposition by actually enumerating

examples and adding "etc.". And If I say, "a and b are the same length; if the length of a is L, then the length of b is L; if a is 5 m long then b is 5 m long, if a is 7 m long, then b is 7 m long, etc.", I am repeating the same proposition. The third formulation shows that the "and" in the proposition doesn't stand between two forms, as it does in " $(\exists x).\phi x.\psi x$ ", where one can also write " $(\exists x).\phi x$ " and " $(\exists x).\psi x$ ".

Let us take as an example the proposition "there are the same number of apples in each of the two boxes". If we write this proposition in the form "there is a number that is the number of the apples in each of the boxes" here too we cannot construct the form "there is a number that is the number of apples in this box" or "the apples in this box have a number". If I write: $(\exists x).\phi x.\sim(\exists x, y).\phi x.\phi y. = .(\exists_n 1x).\phi x. = \phi 1$, etc. then we might write the proposition "the number of apples in both boxes is the same" as " $(\exists x).\phi n.\psi n$ ". But " $(\exists n).\phi n$ " would not be a proposition.

If you want to write the proposition "the same number of objects fall under ϕ and ψ " in a perspicuous notation, the first temptation is to write it in the form " $\phi n.\psi n$ ". And that doesn't feel as if it were a logical product of ϕn and ψn , which would mean that it made sense to write $\phi n.\psi 5$; it is essential that the same letter should follow ψ as follows ϕ , and $\phi n.\psi n$ is an abstraction from the logical products $\phi 4.\psi 4$, $\phi 5.\psi 5$, etc., rather than itself a logical product. (So ϕn doesn't follow from $\phi n.\psi n$. The relation of $\phi n \cdot \psi n$ to a logical product is more like that of a differential quotient to a quotient.) It is no more a logical product than the photograph of a family group is a group of photographs. Therefore the form " $\phi n.\psi n$ " can be misleading and perhaps we should prefer a notation of the form " $\overline{\phi n, \psi n}$ "; or even " $(\exists n).\phi n.\psi n$ ", provided that the grammar of this sign is fixed. We can then stipulate $(\exists n).\phi n = \text{Taut.}$, which is the same as $(\exists n).\phi n.p. = .p$.

Therefore $(\exists n).\phi n \vee \psi n. = \text{Taut.}$, $(\exists n).\phi n. \supset \psi n. = \text{Taut.}$, $(\exists n).\phi n|\psi n. = \text{Cont.}$, etc.

$$\begin{aligned} \phi 1.\psi 1.(\exists n).\phi n.\psi n &= .\phi 1.(\exists n).\phi n.\psi n \\ \phi 2.\psi 2.(\exists n).\phi n.\psi n &= .\phi 2.(\exists n).\phi n.\psi n \\ \text{etc. ad inf.} \end{aligned}$$

And in general the calculation rules for $(\exists n)\phi n.\psi n$ can be derived from the fact that we can write

$$(\exists n).\phi n.\psi n = \phi 0.\psi 0. \vee .\phi 1.\psi 1. \vee .\phi 2.\psi 2. \vee .\phi 3.\psi 3$$

and so on ad inf.

It is clear that this is not a logical sum, because "and so on ad inf." is not a sentence. The notation $(\exists n).\phi n.\psi n$ however is not proof against misunderstanding, because you might wonder why you shouldn't be able to put Φn instead of $\phi n.\psi n$ though if you did $(\exists n).\Phi n$ should of course be meaningless. Of course we can clear that up by going back to the notation $\sim(\exists x).\phi x$ for $\phi 0$, $(\exists x)\phi x.\sim(\exists x,y).\phi x.\phi y$ for $\phi 1$, etc., i.e. to $(\exists_n 0x).\phi x$ for $\phi 0$, $(\exists_n 1x).\phi x$ for $\phi 1$ respectively, and so on. For then we can distinguish between

$$(\exists_n 1x).\phi x(\exists_n 1x).\psi x \text{ and } (\exists_n 1x).\phi x.\psi x$$

And if we go back to $(\exists n).\phi n.\psi n$, that means $(\exists n):(\exists_n nx).\phi x.(\exists_n nx).\psi x$ (which is not nonsensical) and not $(\exists n):(\exists_n nx).\phi x.\psi x$, which is nonsensical.

The expressions "same number", "same length", "same colour", etc. have grammars which are similar but not the same. In each case it is tempting to regard the proposition as an endless logical sum whose terms have the form $\phi n.\psi n$. Moreover, each of these words has several different meanings, i.e. can itself be replaced by several words with different grammars. For "same number" does not mean the same when applied to lines simultaneously present in the visual field as in connection with the apples in two boxes; and "same length" applied in visual space is different from "same length" in Euclidean space; and the meaning of "same colour" depends on the criterion we adopt for sameness of colour.

If we are talking about patches in the visual field seen simultaneously, the expression "same length" varies in

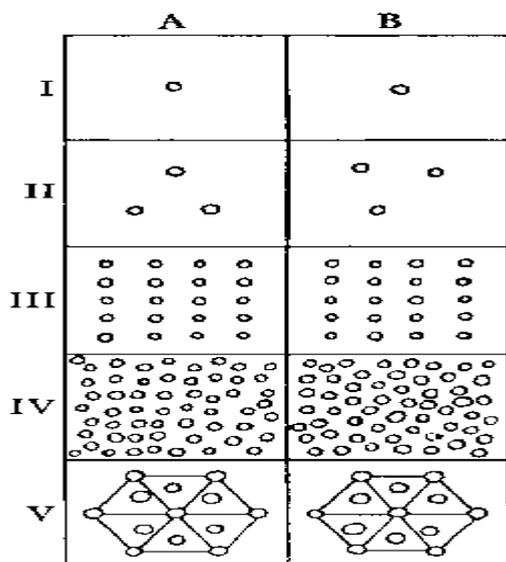

meaning

Page Break 354

depending on whether the lines are immediately adjacent or at a distance from each other. In word-language we often get out of the difficulty by using the expression "it looks".

Page 354

Sameness of number, when it is a matter of a number of lines "that one can take in at a glance", is a different sameness from that which can only be established by counting the lines.

Page 354

Different criteria for sameness of number: in I and II the number that one immediately recognizes; in III the criterion of correlation; in IV we have to count both groups; in V we recognize the same pattern. (Of course these are not the only cases.)

Page 354

We want to say that equality of length in Euclidean space consists in both lines measuring the same number of cm, both 5 cm, both 10 cm etc.; but where it is a case of two lines in visual space being equally long, there is no length L that both lines have.

Page Break 355

Page 355

One wants to say: two rods must always have either the same length or different lengths. But what does that mean? What it is, of course, is a rule about modes of expression. "There must either be the same number or a different number of apples in the two boxes." The method whereby I discover whether two lines are of the same length is supposed to be the laying of a ruler against each line: but do they have the same length when the rulers are *not* applied? In that case we would say we don't know whether during that time the two lines have the same or different lengths. But we might also say that during that time they have no length, or perhaps no numerical length.

Page 355

Something similar, if not exactly the same, holds of sameness between numbers.

Page 355

When we cannot immediately see the number of dots in a group, we can sometimes keep the group in view as a whole while we count, so that it makes sense to say it hasn't altered during the counting. It is different when we have a group of bodies or patches that we cannot keep in a single view while we count them, so that we don't have the same criterion for the group's not changing while it is counted.

Page 355

Russell's definition of sameness of number is unsatisfactory for various reasons. The truth is that in mathematics we don't need any such definition of sameness of number. He puts the cart before the horse.

Page 355

What seduces us into accepting the Russellian or Fregean explanation is the thought that two classes of objects (apples in two boxes) have the same number if they *can* be correlated 1 to 1. We imagine correlation as a check of sameness of number. And here we do distinguish in thought between being correlated and being connected by a relation; and correlation becomes something that is related to connection as the "geometrical straight line" is

related to a real line, namely a kind of ideal connection that is as it were sketched in advance by Logic so that reality only has to trace it. It is possibility conceived as a shadowy actuality. This in turn is connected with the idea of $(\exists x).\phi x$ as an expression of the possibility of ϕx .

" ϕ and ψ have the same number" (I will write this " $S(\phi, \psi)$ " or simply " S ") is supposed to follow from " $\phi 5.\psi 5$ "; but it doesn't follow from $\phi 5.\psi 5$ that ϕ and ψ are connected by a 1-1 relation R (this I will write $\Pi(\phi, \psi)$ or " Π "). We get out of the difficulty by saying that in that case there is a relation like

$$"x = a.y = b. \vee .x = c.y = d.\vee., \text{ etc.}"$$

But if so, then in the first place why don't we define S without more ado as the holding of such a relation? And if you reply that this definition wouldn't include sameness of number in the case of infinite numbers, we shall have to say that this only boils down to a question of "elegance", because for finite numbers in the end I have to take refuge in "extensional" relations. But these too get us nowhere; because saying that between ϕ and ψ there holds a relation e.g. of the form $x = a.y = b. \vee .x = c.y = d$ says only that

$$(\exists x, y).\phi x.\psi y.\sim(\exists x, y, z).\phi x.\phi y.\phi z:(\exists x, y)\psi x.\psi y.\sim(\exists x, y, z).\psi x.\psi y.\psi z.$$

(Which I write in the form

$$(\exists_n 2x).\phi x.(\exists_n 2x).\psi x.)$$

And saying that between ϕ and ψ there holds *one* of the relations $x = a.y = b; x = a.y = b. \vee .x = c.y = d; \text{ etc.}$ etc. means only that there obtains one of the facts $\phi 1.\psi 1; \phi 2.\psi 2$ etc. etc. Then we retreat into greater generality, saying that between ϕ and ψ there holds *some* 1-1 relation, forgetting that in order to specify this generality we have to make the rule that "some relation" includes also relations of the form $x = a.y = b, \text{ etc.}$ By saying more one does

not avoid saying the less that is supposed to be contained in the more. Logic cannot be duped.

So in the sense of S in which S follows from $\phi 5.\psi 5$, it is not defined by Russell's definition. Instead, what we need is a series of definitions.

$$\left. \begin{array}{l} \phi_0.S = \phi_0.\psi_0 = \psi_0.S \\ \phi_1.S = \phi_1.\psi_1 = \psi_1.S \\ \text{etc. ad inf.} \end{array} \right\} \dots \alpha$$

On the other hand Π is used as a criterion of sameness of number and of course *in another sense of S* it can also be equated with S . (And then we can only say: if in a given notation $S = \Pi$, then S means the same as Π .)

Though Π does not follow from $\phi 5.\psi 5$, $\phi 5.\psi 5$ does from $\Pi.\phi 5$.

$$\Pi.\phi 5 = \Pi.\phi 5.\psi 5 = \Pi.\psi 5$$

etc.

We can therefore write:

$$\begin{array}{l} \Pi.\phi 0 = \Pi.\phi 0.\psi 0 = \Pi.\psi 0.S \\ \Pi.\phi 1 = \Pi.\phi 1.\psi 1 = \Pi.\psi 1.S \quad \dots \beta \\ \Pi.\phi 2 = \Pi.\phi 2.\psi 2 = \Pi.\psi 2.S \\ \text{and so on ad inf.} \end{array}$$

And we can express this by saying that the sameness of number follows from Π . And we can also give the rule $\Pi.S = \Pi$; it accords with the rules, or *the* rule, β and the rule α .

We could perfectly well drop the rule " S follows from Π ", that is, $\Pi.S = \Pi$; the rule β does the same job.

If we write S in the form

$\phi_0.\psi_0. \vee.\phi_1.\psi_1. \vee.\phi_2.\psi_2. \vee\dots$ ad inf.

we can easily derive $\Pi.S = \Pi$ by grammatical rules that correspond to ordinary language. For

$(\phi_0.\psi_0. \vee.\phi_1.\psi_1. \vee \text{etc. ad inf.}).\Pi = \phi_0.\psi_0.\Pi. \vee.\phi_1.\psi_1 \Pi. \vee \text{etc. ad inf.} = \phi_0.\Pi. \vee \phi_1.\Pi. \vee \phi_2.\Pi. \vee . \text{etc. ad inf.} = \Pi.(\phi_0 \vee \phi_1 \vee \phi_2 \vee \text{etc. ad inf.}) = \Pi$

The proposition " $\phi_0 \vee \phi_1 \vee \phi_2 \vee \text{etc. ad inf.}$ " must be treated as a tautology.

Page Break 358

⋮
-
▪ ▪
▪ ▪
▪ ▪
▪ ▪

We can regard the concept of sameness of number in such a way that it makes no sense to attribute sameness of number or its opposite to two groups of points except in the case of two series of which one is correlated 1-1 to at least a part of the other. Between such series all we can talk about is unilateral or mutual inclusion.

Page 358

This has really no more connection with particular numbers than equality or inequality of length in the visual field has with numerical measurement. We *can*, but need not, connect it with numbers. If we connect it with the number series, then the relation of mutual inclusion or equality of length between the rows becomes a relation of sameness of number. But then it isn't only that ψ_5 follows from $\Pi.\phi_5$. We also have Π following from $\phi_5.\psi_5$. That means that here $S = \Pi$.

Page Break 359

V MATHEMATICAL PROOF

22

In other cases, if I am looking for something, then even before it is found I can describe what finding it is; not so, if I am looking for the solution of a mathematical problem.

Mathematical Expeditions and Polar Expeditions

Page 359

How can there be conjectures in Mathematics? Or better, what sort of thing is it that looks like a conjecture in mathematics? Such as making a conjecture about the distribution of the primes.

Page 359

I might e.g. imagine that someone is writing primes in series in front of me without my knowing they are the primes--I might for instance believe he is writing numbers just as they occur to him--and I now try to detect a law in them. I might now actually form an hypothesis about this number sequence, just as I could about any sequence yielded by an experiment in physics.

Page 359

Now in what sense have I, by so doing, made an hypothesis about the distribution of the primes?

Page 359

You might say that an hypothesis in mathematics has the value that it trains your thoughts on a particular object--I mean a particular region--and we might say "we shall surely discover something interesting about these things".

Page 359

The trouble is that our language uses each of the words "question", "problem", "investigation", "discovery", to refer to such basically different things. It's the same with "inference", "proposition", "proof".

Page 359

The question again arises, what kind of verification do I count as valid for my hypothesis? Or can I *faute de mieux* allow an empirical one to hold for the time being until I have a "strict proof"? No. Until there is such a proof, there is no connection at all between my hypothesis and the "concept" of a prime number.

Page Break 360

Only the so-called proof establishes any connection between the hypothesis and the primes *as such*. And that is shown by the fact that--as I've said--until then the hypothesis can be construed as one belonging purely to physics.--On the other hand when we have supplied a proof, it doesn't prove what was conjectured at all, since I can't conjecture to infinity. I can only conjecture what can be confirmed, but experience can only confirm a finite number of conjectures, and you can't conjecture the proof until you've got it, and not then either.

Suppose that someone, without having proved Pythagoras' theorem, has been led by measuring the sides and hypoteneuses of right angled triangles to "conjecture" it. And suppose he later discovered the proof, and said that he had then proved what he had earlier conjectured. At least one remarkable question arises: at what point of the proof does what he had earlier confirmed by individual trials emerge? For the proof is essentially different from the earlier method.--Where do these methods make contact, if the proof and the tests are only different aspects of the same thing (the same generalisation) if, as alleged, there is some sense in which they give the same result?

I have said: "from a single source only one stream flows", and one might say that it would be odd if the same thing were to come from such different sources. The thought that the same thing can come from different sources is familiar from physics, i.e. from hypotheses. In that area we are always concluding from symptoms to illnesses and we know that the most different symptoms can be symptoms of the same thing.

How could one guess from statistics the very thing the proof later showed?

How can the proof produce the same generalisation as the earlier trials made probable?

I am assuming that I conjectured the generalisation without conjecturing the proof. Does the proof now prove exactly the generalisation that I conjectured?!

Suppose someone was investigating even numbers to see if they confirmed Goldbach's conjecture. Suppose he expressed the conjecture--and it can be expressed--that if he continued with this investigation, he would never meet a counterexample as long as he lived. If a proof of the theorem is then discovered, will it also be a proof of the man's conjecture? How is that possible?

Nothing is more fatal to philosophical understanding than the notion of proof and experience as two different but comparable methods of verification.

What kind of discovery did Sheffer make when he found that $p \vee q$ and $\sim p$ can be expressed by $p|q$? People had no method of looking for $p|q$, and if someone were to find one today, it wouldn't make any difference.

What was it we didn't know before the discovery? (It wasn't anything that we didn't know, it was something with which we weren't acquainted.)

You can see this very clearly if you imagine someone objecting that $p|p$ isn't at all the same as is said by $\sim p$. The reply of course is that it's only a question of the system $p|q$, etc. having the necessary multiplicity. Thus Sheffer found a symbolic system with the necessary multiplicity.

Does it count as looking for something, if I am unaware of Sheffer's system and say I would like to construct a system with only *one* logical constant? No!

Systems are certainly not all in *one* space, so that I could say: there are systems with 3 and with 2 logical constants and now I am trying to reduce the number of constants *in the same way*. There is no "*same way*" here.

Suppose prizes are offered for the solution--say--of Fermat's problem. Someone might object to me: How can you say that this problem doesn't exist? If prizes are offered for the solution, then surely the problem must exist. I would have to say: Certainly, but the people who talk about it don't understand the grammar of the expression

"mathematical problem" or of the word "solution". The prize is really offered for the solution of a scientific problem; for the *exterior* of the solution (hence also for instance we talk about a Riemannian *hypothesis*). The conditions of the problem are external conditions; and when the problem is solved, what happens corresponds to the setting of the problem in the way in which solutions correspond to problems in physics.

Page 362

If we set as a problem to find a construction for a regular pentagon, the way the construction is specified in the setting of the problem is by the physical attribute that it is to yield a pentagon that *is shown by measurement* to be regular. For we don't get the concept of *constructive division into five* (or of a *constructive pentagon*) until we get it from the construction.

Page 362

Similarly in Fermat's theorem we have an empirical structure that we interpret as a *hypothesis*, and not--of course--as the product of a construction. So in a certain sense what the problem asks for is not what the solution gives.

Page 362

Of course a proof of the contradictory of Fermat's theorem (for instance) stands in the same relation to the problem as a proof of the proposition itself. (Proof of the impossibility of a construction.)

Page 362

We can represent the impossibility of the trisection of an angle as a physical impossibility, by saying things like "don't try to divide the angle into 3 equal parts, it is hopeless!" But in so far as we can do that, it is not *this* that the "proof of impossibility" proves. That it is *hopeless* to attempt the trisection is something connected with physical facts.

Page Break 363

Page 363

Imagine someone set himself the following problem. He is to discover a game played on a chessboard, in which each player is to have 8 pieces; the two white ones which are in the outermost files at the beginning of the game (the "consuls") are to be given some special status by the rules so that they have a greater freedom of movement than the other pieces; one of the black pieces (the "general") is to have a special status; a white piece takes a black one by being put in its place (and vice versa); the whole game is to have a certain analogy with the Punic wars. Those are the conditions that the game is to satisfy.--There is no doubt that that is a problem, a problem not at all like the problem of finding out how under certain conditions white can win in chess.--But now imagine the problem: "How can white win in 20 moves in the war-game whose rules we don't yet know precisely?"--That problem would be quite analogous to the problems of mathematics (other than problems of calculation).

Page 363

What is hidden must be capable of being found. (Hidden contradictions.)

Page 363

Also, what is hidden must be completely describable before it is found, no less than if it had already been found.

Page 363

It makes good sense to say that an object is so well hidden that it is impossible to find it; but of course the impossibility [[sic]] here is not a logical one; i.e. it makes *sense* to speak of finding an object to describe the finding; we are merely denying that it will happen.

Page 363

[We might put it like this: If I am looking for something,--I mean, the North Pole, or a house in London--I can *completely* describe what I am looking for before I have found it (or have found that it isn't there) and either way this description will be logically acceptable. But when I'm "looking for" something in mathematics, unless I am doing so *within* a system, what I am looking for cannot be described, or can only apparently be described; for if I could describe it in every particular, I would already

Page Break 364

actually *have* it; and before it is *completely* described I can't be sure whether *what* I am looking for is logically acceptable, and therefore describable at all. That is to say, the incomplete description leaves out just what is necessary for something to be capable of being looked for at all. So it is only an apparent description of what is being "looked for."†1

Page 364

Here we are easily misled by the legitimacy of an incomplete description when we are looking for a real object, and here again there is an unclarity about the concepts "description" and "object". If someone says, I am

going to the North Pole and I expect to find a flag there, that would mean, on Russell's account, I expect to find something (an x) that is a flag--say of such and such a colour and size. In that case too it looks as if the expectation (the search) concerns only an indirect knowledge and not the object itself; as if that is something that I don't really know (knowledge by acquaintance) until I have it in front of me (having previously been only indirectly acquainted with it). But that is nonsense. There whatever I can perceive--to the extent that it is a fulfilment of my expectation--I can also describe in advance. And here "describe" means not saying something or other about it, but rather expressing it. That is, if I am looking for something I must be *able* to describe it *completely*.

Page 364

The question is: can one say that at present mathematics is as it were jagged--or frayed--and for that reason we shall be able to round it off? I think you can't say that, any more than you can say that reality is untidy, because there are 4 primary colours, seven notes in an octave, three dimensions in visual space, etc.

Page 364

You can't round off mathematics any more than you can say "let's round off the four primary colours to eight or ten" or "let's round off the eight tones in an octave to ten".

Page Break 365

Page 365

The comparison between a mathematical expedition and a polar expedition. There is a point in drawing this comparison and it is a very useful one.

Page 365

How strange it would be if a geographical expedition were uncertain whether it had a goal, and so whether it had any route whatsoever. We can't imagine such a thing, it's nonsense. But this is precisely what it is like in a mathematical expedition. And so perhaps it is a good idea to drop the comparison altogether.

Page 365

Could one say that arithmetical or geometrical problems can always look, or can falsely be conceived, as if they referred to objects in space whereas they refer to space itself?

Page 365

By "space" I mean what one can be *certain* of while searching.

Page Break 366

Proof and the truth and falsehood of mathematical propositions

Page 366

A mathematical proposition that has been proved has a bias towards truth in its grammar. In order to understand the sense of $25 \times 25 = 625$ I may ask: how is this proposition proved? But I can't ask how its contradictory is or would be proved, because it makes no sense to speak of a proof of the contradictory of $25 \times 25 = 625$. So if I want to raise a question which won't depend on the truth of the proposition, I have to speak of *checking* its truth, not of proving or disproving it. The method of checking corresponds to what one may call the sense of the mathematical proposition. The description of this method is a general one and brings in a system of propositions, for instance of propositions of the form $a \times b = c$.

Page 366

We can't say "I will work out *that* it is so", we have to say "*whether* it is so", i.e., whether it is *so* or otherwise.

Page 366

The method of checking the truth corresponds to the sense of a mathematical proposition. If it's impossible to speak of such a check, then the analogy between "mathematical proposition" and the other things we call propositions collapses. Thus there is a check for propositions of the form " $(\exists k)_n \dots$ " and " $\sim(\exists k)_n \dots$ " which bring in intervals.

Page 366

Now consider the question "does the equation $x^2 + ax + b = 0$ have a solution in the real numbers?". Here again there is a check and the check decides between $(\exists \dots)$, etc. and $\sim(\exists \dots)$, etc. But can I in the same sense also ask and check "whether the equation has a solution"? Not unless I include this case too in a system with others.

Page 366

(In reality the "proof of the fundamental theorem of algebra..." constructs a new kind of number.)

Equations are a kind of number. (That is, they can be treated similarly to the numbers.)

A "proposition of mathematics" that is proved by an induction is not a "proposition" in the same sense as the answer to a mathematical question unless one can look for the induction in a system of checks.

"Every equation G has a root." And suppose it has no root? Could we describe that case as we can describe its not having a rational solution? What is the criterion for an equation not having a solution? For this criterion must be given if the mathematical *question* is to have a sense and if the apparent existence proposition is to be a "proposition" in the sense of an answer to a question.

(What does the description of the contradictory consist of? What supports it? What are the examples that support it, and how are they related to particular cases of the proved contradictory? These questions are not side-issues, but absolutely essential.)

(The philosophy of mathematics consists in an exact scrutiny of mathematical proofs--not in surrounding mathematics with a vapour.)

In discussions of the provability of mathematical propositions it is sometimes said that there are substantial propositions of mathematics whose truth or falsehood must remain undecided. What the people who say that don't realize is that such propositions, *if* we can use them and want to call them "propositions", are not at all the same as what are called "propositions" in other cases; because a proof alters the grammar of a proposition. You can certainly use one and the same piece of wood first as a weathervane and then as a signpost; but you can't use it fixed as a weathervane and moving as a signpost. If some one wanted to say "There are also moving signposts" I would answer "You really mean 'There are also moving *pieces of wood*'. I don't say that a moving piece of wood can't possibly be used at all, but only that it can't be used as a signpost".

The word "proposition", if it is to have any meaning at all here, is equivalent to a calculus: to a calculus in which $p \vee \sim p$ is a tautology (in which the "law of the excluded middle" holds). When it is supposed not to hold, we have altered the concept of proposition. But that does not mean we have made a discovery (found something that is a proposition and yet doesn't obey such and such a law); it means we have made a new stipulation, or set up a new game.

If you want to know what is proved, look at the proof

Mathematicians only go astray, when they want to talk about calculi in general; they do so because they forget the particular stipulations that are the foundations of each particular calculus.

The reason why all philosophers of mathematics miss their way is that in logic, unlike natural history, one cannot justify generalizations by examples. Each particular case has maximum significance, but once you have it the story is complete, and you can't draw from it any general conclusion (or any conclusion *at all*).

There is no such thing as a logical fiction and hence you can't work with logical fictions; you have to work out each example fully.

In mathematics there can only be mathematical troubles, there can't be philosophical ones.

The philosopher only marks what the mathematician casually throws off about his activities.

The philosopher easily gets into the position of a ham-fisted director, who, instead of doing his own work and merely supervising his employees to see they do their work well, takes over their jobs until one day he finds himself overburdened with other people's work while his employees watch and criticize him. He is particularly

inclined to saddle himself with the work of the mathematician.

Page 369

If you want to know what the expression "continuity of a function" means, look at the proof of continuity; that will show what it proves. Don't look at the result as it is expressed in prose, or in the Russellian notation, which is simply a translation of the prose expression; but fix your attention on the calculation actually going

Page Break 370

on in the proof. The verbal expression of the allegedly proved proposition is in most cases misleading, because it conceals the real purport of the proof, which can be seen with full clarity in the proof itself.

Page 370

"Is the equation satisfied by any numbers?"; "It is satisfied by numbers"; "It is satisfied by all (no) numbers." Does your calculus have proofs? And what proofs? It is only from them that we will be able to gather the sense of these proportions and questions.

Page 370

Tell me *how* you seek and I will tell you *what* you are seeking.

Page 370

We must first ask ourselves: is the mathematical proposition proved? If so, how? For the proof is part of the grammar of the proposition!--The fact that this is so often not understood arises from our thinking once again along the lines of a misleading analogy. As usual in these cases, it is an analogy from our thinking in natural sciences. We say, for example, "this man died two hours ago" and if someone asks us "how can you tell that?" we can give a series of indications (symptoms). But we also leave open the possibility that medicine may discover hitherto unknown methods of ascertaining the time of death. That means that we can already describe such possible methods; it isn't their description that is discovered. What is ascertained experimentally is whether the description corresponds to the facts. For example, I may say: one method consists in discovering the quantity of haemoglobin in the blood, because this diminishes according to such and such a law in proportion to the time after death. Of course that isn't correct, but if it were correct, nothing in my imaginary description would change. If you call the medical discovery "the discovery of a proof that the man died two hours ago" you must go on to say that this discovery does not change anything in the grammar of the proposition "the man died two hours ago". The discovery is the discovery that a particular hypothesis is true (or: agrees with

Page Break 371

the facts). We are so accustomed to these ways of thinking, that we take the discovery of a proof in mathematics, sight unseen, as being the same or similar. We are wrong to do so because, to put it concisely, the mathematical proof couldn't be described before it is discovered.

Page 371

The "medical proof" didn't incorporate the hypothesis it proved into any new calculus, so it didn't give it any new sense; a mathematical proof incorporates the mathematical proposition into a new calculus, and alters its position in mathematics. The proposition with its proof doesn't belong to the same category as the proposition without the proof. (Unproved mathematical propositions--signposts for mathematical investigation, stimuli to mathematical constructions.)

Page 371

Are all the variables in the following equations variables of the same kind?

$$x^2 + y^2 + 2xy = (x + y)^2$$

$$x^2 + 3x + 2 = 0$$

$$x^2 + ax + b = 0$$

$$x^2 + xy + z = 0?$$

Page 371

That depends on the use of the equations.--But the distinction between no. 1 and no. 2 (as they are ordinarily used) is not a matter of the extension of the values satisfying them. How do you prove the proposition "No. 1 holds for all values of x and y" and how do you prove the proposition "there are values of x that satisfy No. 2?" There is no more and no less similarity between the senses of the two propositions than there is between the proofs.

Page 371

But can't I say of an equation "I know it doesn't hold for some substitutions--I've forgotten now *which*; but whether it doesn't hold in general, I don't know?" But what do you mean when you say you know that? How do you know? Behind the words "I know..." there isn't a certain state of mind to be the sense of those words. What can you do with that knowledge? That's what

will show what the knowledge consists in. Do you know a method for ascertaining that the equation doesn't hold in general? Do you remember that the equation doesn't hold for some values of x between 0 and 1000? Or did someone just show you the equation and say he had found values of x that didn't satisfy the equation, so that perhaps you don't yourself know how to establish it for a given value? etc. etc.

"I have worked out that there is no number that..."--In what system of calculation does that calculation occur?--That will show us to which proposition-system the worked-out proposition belongs. (One also asks: "how does one work out *something like that*?")

"I have discovered that there is such a number."

"I have worked out that there is no such number."

In the first sentence I cannot substitute "no such" for "such a". What if in the second I put "such a" for "no such"? Let's suppose the result of a calculation isn't the proposition " $\sim(\exists n)$ " but " $(\exists n)$ etc." Does it then make sense to say something like "Cheer up! *Sooner or later* you must come to such a number, if only you try long enough"? That would only make sense if the result of the proof had not been " $(\exists n)$ etc." but something that sets limits to testing, and therefore a quite different result. That is, the contradictory of what we call an existence theorem, a theorem that tells us to look for a number, is not the proposition " (n) etc." but a proposition that says in such and such an interval there is no number which... What is the contradictory of what is proved?--For that you must look at the proof. We can say that the contradictory of a proved proposition is what would have been proved instead of it if a particular miscalculation had been made in the proof. If now, for instance, the proof that $\sim(\exists n)$ etc is the case is an induction that shows that however far I go such a number cannot occur, the contradictory of this proof (using this expression for the sake of argument) is not an existence proof in our sense. This case isn't like a proof that one or none of the numbers a, b, c, d has the

property ϵ ; and that is the case that one always has before one's mind as a paradigm. In that case I could make a mistake by believing that c had the property and after I had seen the error I would know that *none* of the numbers had the property. But at this point the analogy just collapses.

(This is connected with the fact that I can't eo ipso use the negations of equations in every calculus in which I use equations. For $2 \times 3 \neq 7$ doesn't mean that the equation $2 \times 3 = 7$ isn't to occur, like the equation $2 \times 3 = \text{sine}$; the negation is an exclusion within a predetermined system. I can't negate a definition as I can negate an equation derived by rules.)

If you say that in an existence proof the interval isn't essential, because another interval might have done as well, of course that doesn't mean that not specifying an interval would have done as well.--The relation of a proof of non-existence to a proof of existence is not the same as that of a proof of p to a proof of its contradictory.

One should suppose that in a proof of the contradictory of " $(\exists n)$ " it must be possible for a negation to creep in which would enable " $\sim(\exists n)$ " to be proved erroneously. Let's for once start at the other end with the proofs, and suppose we were shown them first and then asked: what do these calculations prove? Look at the proofs and *then* decide what they prove.

I don't need to *assert* that it must be possible to construct the n roots of equations of the n -th degree; I merely say that the proposition "this equation has n roots" hasn't *the same* meaning if I've proved it by enumerating the constructed roots as if I've proved it in a different way. If I find a formula for the roots of an equation, I've constructed a new calculus; I haven't filled in a gap in an old one.

Hence it is nonsense to say that the proposition isn't proved until such a construction is produced. For when we do that we construct

something new, and what we now mean by the fundamental theorem of algebra is what the present 'proof' shows us.

"Every existence proof must contain a construction of what it proves the existence of." You can only say "I won't call anything an 'existence proof' unless it contains such a construction". The mistake lies in pretending to possess a clear *concept* of existence.

Page 374

We think we can prove a something, existence, in such a way that we are then convinced of it *independently of the proof*. (The idea of proofs independent of each other--and so presumably independent of what is proved.) Really, existence is what is proved by the procedures we call "existence proofs". When the intuitionists and others talk about this they say: "This state of affairs, existence, can be proved only thus and not thus." And they don't see that by saying that they have simply defined what *they* call existence. For it isn't at all like saying "that a man is in the room can only be proved by looking inside, not by listening at the door".

Page 374

We have no concept of existence independent of our concept of an existence proof.

Page 374

Why do I say that we don't discover a proposition like the fundamental theorem of algebra, and that we merely construct it?--Because in proving it we give it a new sense that it didn't have before. Before the so-called proof there was only a rough pattern of that sense in the word-language.

Page 374

Suppose someone were to say: chess only had to be *discovered*, it was always there! Or: the *pure* game of chess was always there; we only made the material game alloyed with matter.

Page 374

If a calculus in mathematics is altered by discoveries, can't we preserve the old calculus? (That is, do we have to throw it away?)

Page Break 375

That is a very interesting way of looking at the matter. After the discovery of the North Pole we don't have two earths, one with and one without the North pole. But after the discovery of the law of the distribution of the primes, we do have two kinds of primes.

Page 375

A mathematical question must be no less exact than a mathematical proposition. You can see the misleading way in which the mode of expression of word-language represents the sense of mathematical propositions if you call to mind the multiplicity of a mathematical proof and consider that the proof belongs to the *sense* of the proved proposition, i.e. determines that sense. It isn't something that brings it about that we believe a particular proposition, but something that shows us *what* we believe--if we can talk of believing here at all. In mathematics there are concept words: cardinal number, prime number, etc. That is why it seems to make sense straight off if we ask "how many prime numbers are there?" (Human beings believe, if only they hear words...) In reality this combination of words is so far nonsense; until it's given a special syntax. Look at the proof "that there are infinitely many primes," and then at the question that it appears to answer. The result of an intricate proof can have a simple verbal expression only if the system of expressions to which this expression belongs has a multiplicity corresponding to a system of such proofs. Confusions in these matters are entirely the result of treating mathematics as a kind of natural science. And this is connected with the fact that mathematics has detached itself from natural science; for, as long as it is done in immediate connection with physics, it is clear that *it* isn't a natural science. (Similarly, you can't mistake a broom for part of the furnishing of a room as long as you use it to clean the furniture).

Page 375

The main danger is surely that the prose expression of the result of a mathematical operation may give the illusion of a calculus that doesn't exist, by bearing the outward appearance of belonging to a system that isn't there at all.

Page Break 376

Page 376

A proof is a proof of a particular proposition if it goes by a rule correlating the proposition to the proof. That is, the proposition must belong to a system of propositions, and the proof to a system of proofs. And every proposition in mathematics must belong to a calculus of mathematics. (It cannot sit in solitary glory and refuse to mix with other propositions.)

Page 376

So even the proposition "every equation of nth degree has n roots" isn't a proposition of mathematics unless it corresponds to a system of propositions and its proof corresponds to an appropriate system of proofs. For what good reason have I to correlate that chain of equations etc. (that we call the proof) to *this* prose sentence? Must it

not be clear--according to a rule--from the proof itself which proposition it is a proof of?

Page 376

Now it is a part of the nature of *what we call propositions* that they must be capable of being negated. And the negation of what is proved also must be connected with the proof; we must, that is, be able to show in what different, contrasting, conditions it would have been the result.

Page Break 377

25
*Mathematical problems,
Kinds of problem,
Search
"Projects" in mathematics*

Page 377

Where you can ask you can look for an answer, and where you cannot look for an answer you cannot ask either. Nor can you find an answer.

Page 377

Where there is no method of looking for an answer, there the question too cannot have any sense.--Only where there is a method of solution is there a question (of course that doesn't mean: "only where the solution has been found is there a question"). That is: where we can only expect the solution of the problem from some sort of revelation, there isn't even a question. To a revelation no question corresponds.

Page 377

The supposition of undecidability presupposes that there is, so to speak, an underground connection between the two sides of an equation; that though the bridge cannot be built in symbols, it does exist, because otherwise the equation would lack sense.--But the connection only exists if we have made it by symbols; the transition isn't produced by some dark speculation different in kind from what it connects (like a dark passage between two sunlit places).

Page 377

I cannot use the expression "the equation E yields the solution S" unambiguously until I have a method of solution; because "yields" refers to a structure that I cannot designate unless I am acquainted with it. For that would mean using the word "yields" without knowing its grammar. But I might also say: When I use the word "yields" in such a way as to bring in a method of solution, it doesn't have the same meaning as when this isn't the case. Here the word "yields" is like the word "win" (or "lose") when at one time the criterion for "winning" is a particular set of events in the game (in that case I must know the rules of the game in order to be able to say that someone has won) and at another by "winning"

Page Break 378

I mean something that I could express roughly by "must pay".

Page 378

If we employ "yields" in the first meaning, then "the equation yield S" means: if I transform the equation in accordance with certain rules, I get S. Just as the equation $25 \times 25 = 620$ says that I get 620 if I apply the rules for multiplication to 25×25 . But in this case these rules must already be given to me before the word "yields" has a meaning, and before the question whether the equation yields S has a sense.

Page 378

It is not enough to say "p is provable"; we should say: provable according to a particular system.

Page 378

And indeed the proposition doesn't assert that p is provable according to the system S, but according to its own system, the system that p belongs to. That p belongs to the system S cannot be asserted (that has to show itself).--We can't say, p belongs to the system S; we can't ask, to which system does p belong; we cannot search for p's system. "To understand p" means, to know its system. If p appears to cross over from one system to another, it has in fact changed its sense.

Page 378

It is impossible to make discoveries of novel rules holding of a form already familiar to us (say the sine of an angle). If they are new rules, then it is not the old form.

Page 378

If I know the rules of elementary trigonometry, I can check the proposition $\sin 2x = 2 \sin x \cdot \cos x$, but not the

proposition $\sin x = \frac{x}{3!} + \frac{x^5}{5!} \dots$ but that means that the sine function of elementary trigonometry and that of

higher trigonometry are different concepts.

Page 378

The two propositions stand as it were on two different planes. However far I travel on the first plane I will never come to the proposition on the higher plane.

Page 378

A schoolboy, equipped with the armoury of elementary trigonometry and asked to test the equation $\sin x = x - \frac{x^3}{3!}$ simply wouldn't find what he needs to tackle the problem. He not merely couldn't answer the question, he couldn't even understand it.

Page Break 379

(It would be like the task the prince set the smith in the fairy tale: fetch me a 'Fiddle-de-dee'. Busch, *Volksmärchen*).

Page 379

We call it a problem, when we are asked "how many are 25×16 ", but also when we are asked: what is $\int \sin^2 x \, dx$. We regard the first as much easier than the second, but we don't see that they are "problems" in different senses. *Of course* the distinction is not a psychological one; it isn't a question of whether the pupil can solve the problem, but whether the calculus can solve it, or which calculus can solve it.

Page 379

The distinctions to which I can draw attention are ones that are familiar to every schoolboy. Later on we look down on those distinctions, as we do on the Russian abacus (and geometrical proofs using diagrams); we regard them as inessential, instead of seeing them as essential and fundamental.

Page 379

Whether a pupil *knows a rule* for ensuring a solution to $\int \sin^2 x \, dx$ is of no interest; what does interest us is whether the *calculus* we have before us (and that he happens to be using) contains such a rule.

Page 379

What interests us is not whether the pupil can do it, but whether the calculus can do it, and *how it* does it.

Page 379

In the case of $25 \times 16 = 370$ the calculus we use prescribes every step for the checking of the equation.

Page 379

"I *succeeded* in proving this" is a remarkable expression. (That is something no one would say in the case of $25 \times 16 = 400$).

Page 379

One could lay down: "whatever one can tackle is a problem.--Only where there can be a problem, can something be asserted."

Page Break 380

Page 380

Wouldn't all this lead to the paradox that there are no difficult problems in mathematics, since if anything is difficult it isn't a problem? What follows is, that the "difficult mathematical problems", i.e. the problems for mathematical research, aren't in the same relationship to the problem " $25 \times 25 = ?$ " as a feat of acrobatics is to a simple somersault. They aren't related, that is, just as very easy to very difficult; they are 'problems' in different meanings of the word.

Page 380

"You say 'where there is a question, there is also a way to answer it', but in mathematics there are questions that we do not see any way to answer." Quite right, and all that follows from that is that in this case we are not using the word 'question' in the same sense as above. And perhaps I should have said "here there are two different forms and I want to use the word 'question' only for the first". But this latter point is a side-issue. What is important is that we are here concerned with two different forms. (And if you want to say they are just two different *kinds* of question you do not know your way about the grammar of the word "kind".)

Page 380

"I know that there is a solution for this problem, although I don't yet know what kind of solution"†1--In what symbolism do you know it?

Page 380

"I know that here there must be a law." Is this knowledge an amorphous feeling accompanying the utterance of the sentence?

Page Break 381

Page 381

That does not interest us. And if it is a symbolic process--well, then the problem is to represent it in a visible symbolism.

Page 381

What does it mean to *believe* Goldbach's theorem? What does this belief consist in? In a feeling of certainty as we state or hear the theorem? That does not interest us. I don't even know how far this feeling may be caused by the proposition itself. How does the belief connect with this proposition? Let us look and see what are the consequences of this belief, where it takes us. "It makes me search for a proof of the proposition."--Very well; and now let us look and see what your searching really consists in. Then we shall know what belief in the proposition amounts to.

Page 381

We may not overlook a difference between forms--as we may overlook a difference between suits, if it is very slight.

Page 381

For us--that is, in grammar--there are in a certain sense no 'fine distinctions'. And altogether the word distinction doesn't mean at all the same as it does when it is a question of a distinction between two things.

Page 381

A philosopher feels changes in the style of a derivation which a contemporary mathematician passes over calmly with a blank face. What will distinguish the mathematicians of the future from those of today will really be a greater sensitivity, and *that* will--as it were--prune mathematics; since people will then be more intent on absolute clarity than on the discovery of new games.

Page 381

Philosophical clarity will have the same effect on the growth of mathematics as sunlight has on the growth of potato shoots. (In a dark cellar they grow yards long.)

Page 381

A mathematician is bound to be horrified by my mathematical comments, since he has always been trained to avoid indulging in

Page Break 382

thoughts and doubts of the kind I develop. He has learned to regard them as something contemptible and, to use an analogy from psycho-analysis (this paragraph is reminiscent of Freud), he has acquired a revulsion from them as infantile. That is to say, I trot out all the problems that a child learning arithmetic, etc., finds difficult, the problems that education represses without solving. I say to those repressed doubts: you are quite correct, go on asking, demand clarification!

Page Break 383

Page 383

From the inequality

$$1 + 1/2 + 1/3 + 1/4 + \dots \neq (1 + 1/2 + 1/2^2 + 1/2^3 + \dots)(1 + 1/3 + 1/3^2 + \dots)$$

can we derive a number which is still missing from the combinations on the right hand side? Euler's proof that there are infinitely many prime numbers is meant to be an existence proof, but how is such a proof possible without a construction?

$$\sim 1 + 1/2 + 1/3 + \dots = (1 + 1/2 + 1/2^2 + \dots)(1 + 1/3 + 1/3^2 + \dots)$$

The argument goes like this: The product on the right is a series of fractions $1/n$ in whose denominators all multiples of the form $2^v 3^u$ occur; if there were no numbers besides these, then this series would necessarily be the same as the series $1 + 1/2 + 1/3 + \dots$ and in that case the sums also would necessarily be the same. But the left hand side is ∞ and the right hand side only a finite number $2/1 \cdot 3/2 = 3$, so there are infinitely many fractions missing in the right-hand series, that is, *there are* on the left hand side fractions that do not occur on the right. †1 And now the question is: is this argument correct? If it were a question of finite series, everything would be perspicuous. For then the method of summation would enable us to find out which terms occurring in the left hand series were missing from the right hand series. Now we might ask: how does it come about that the left hand series gives ∞ ? What must it contain in addition to the terms on the right to make it infinite? Indeed the question arises: does an equation, like $1 + 1/2 + 1/3 + \dots = 3$ above have any sense at all? I certainly can't find out from it *which* are the extra terms on the left. How do we know that all the terms on the right hand side also occur on the left? In the case of finite series I can't say that until I have ascertained it term by term;--and if I do so I see at the same time which are the extra ones.--Here there is no connection between the result of the sum and the terms, and only such a connection could furnish a proof. Everything becomes clearest if we imagine the business done with a finite equation:

Page Break 384

$$1 + 1/2 + 1/3 + 1/4 + 1/5 + 1/6 \neq (1 + 1/2)(1 + 1/3) = 1 + 1/2 + 1/3 + 1/6$$

Here again we have that remarkable phenomenon that we might call proof by circumstantial evidence in mathematics--something that is absolutely never permitted. It might also be called a proof by *symptoms*. The result of the summation is (or is regarded as) a symptom that there are terms on the left that are missing on the right. The connection between the symptom and what we would like to have proved is a *loose* connection. That is, no bridge has been built, but we rest content with *seeing* the other bank.

Page 384

All the terms on the right hand side occur on the left, but the sum on the left hand side is ∞ and the sum of the right hand side is only a finite number, *so there must...* but in mathematics nothing *must be* except what *is*.

Page 384

The bridge has to be built.

Page 384

In mathematics there are no symptoms: it is only in a psychological sense that there can be symptoms for mathematicians.

Page 384

We might also put it like this: in mathematics nothing can be inferred unless it can be *seen*.

Page 384

That reasoning with all its looseness no doubt rests on the confusion between a sum and the limiting value of a sum.

Page 384

We do see dearly that *however far* we continue the right-hand series we can always continue the left hand one far enough to contain all the terms of the right hand one. (And that leaves it *open* whether it then contains other terms as well).

Page 384

We might also put the question thus: if you had only this proof, what would you bet on it? If we discovered the primes up to N , could we later go on for ever looking for a further prime number--since the proof guarantees that we will find one?--Surely that is nonsense. For "if we only search long enough" has no meaning. (That goes for existence proofs in general).

Page 384

Could I add further prime numbers to the left hand side in this proof? Certainly not, because I don't know how to discover any, and that means that I have no concept of prime number; the proof

Page Break 385

hasn't given me one. I could only add arbitrary numbers (or series).

(Mathematics is dressed up in false interpretations).

("Such a number *has to* turn up" has no meaning in mathematics. That is closely connected with the fact that "in logic nothing is more general or more particular than anything else").

If the numbers were all multiples of 2 and 3 then

$$\left(\lim_{n \rightarrow \infty} \sum_{v=0}^{v=n} \frac{1}{2^v} \right) \cdot \left(\lim_{n \rightarrow \infty} \sum_{v=0}^{v=n} \frac{1}{3^v} \right) \text{ would have to yield } \lim_{n \rightarrow \infty} \sum_{n=1}^{n=n} \frac{1}{n}$$

but it does not... What follows from that? (The law excluded middle). Nothing follows, except that the limiting values of the sums are different; that is, nothing. But now we might investigate how this comes about. And in so doing we may hit on numbers that are not representable as $2^v \cdot 3^\mu$. Thus we shall hit on larger prime numbers, but we will never see that *no* number of such original numbers will suffice for the formulation of all numbers.

$$1 + 1/2 + 1/3 + \dots \neq 1 + 1/2 + 1/2^2 + 1/2^3$$

However many terms of the form $1/2^v$ I take they never add up to more than 2, whereas the first four terms of the left-hand series already add up to more than 2. (So *this* must already contain the proof.) This also gives us at the same time the construction of a number that is not a power of 2, for the rule now says: find a segment of the series that adds up to more than 2: this must contain a number that is not a power of 2.

$$(1 + 1/2 + 1/2^2 + \dots) \cdot (1 + 1/3 + 1/3^3 + \dots) \dots (1 + 1/n + 1/n^2 + \dots) = n$$

If I extend the sum $1 + 1/2 + 1/3 + \dots$ until it is greater than n , this part must contain a term that doesn't occur in the right hand series, for if the right hand series contained all those terms it would yield a larger and not a smaller sum.

The condition for a segment of the series $1 + 1/2 + 1/3 + \dots$ say $1/n + 1/(n+1) + 1/(n+2) + \dots + 1/(n+v)$ being equal to or greater than 1 is as follows.

To make:

$$1/n + 1/(n+1) + 1/(n+2) + \dots + 1/(n+v) \stackrel{!}{\geq} 1.$$

transform the left hand side into:

$$\begin{aligned}
& 1 + \frac{n}{n+1} + \frac{n}{n+2} + \dots + \frac{n}{n+v} = \\
& \frac{1 + \left(1 - \frac{1}{n+1}\right) + \left(1 - \frac{2}{n+2}\right) + \dots + \left(1 - \frac{n-1}{n+(n-1)}\right) + \frac{n}{2n}}{n} + \\
& \frac{\frac{n}{2n+1} + \frac{n}{2n+2} + \dots + \frac{n}{n+v}}{n} = \\
& = \frac{n - \frac{1}{2}n(n-1) \frac{1}{n+1} + (v-n+1) \frac{n}{n+v}}{n} = 1 - \frac{n-1}{2n+2} + \\
& \frac{v-n+1}{n+v} \approx 1 \\
& \therefore 2nv + 2v - 2n^2 - 2n + 2n + 2 - n^2 - nv + n + v \approx 0 \\
& nv + 3v - 3n^2 + 2 + n \approx 0 \\
& v \approx \frac{3n^2 - (n+2)}{n+3} < 3n-1
\end{aligned}$$

Page Break 387

27

The trisection of an angle, etc.

Page 387

We might say: in Euclidean plane geometry we can't look for the trisection of an angle, because there is no such thing, and we can't look for the bisection of an angle, because there is such a thing.

Page 387

In the world of Euclid's Elements I can no more ask for the trisection of an angle than I can search for it. It just isn't mentioned.

Page 387

(I can locate the problem of the trisection of an angle within a larger system but can't ask within the system of Euclidean geometry whether it's soluble. In what *language* should I ask this? In the Euclidean?--But neither can I ask in Euclidean language about the possibility of bisecting an angle within the Euclidean system. For in that language that would boil down to a question about absolute possibility, which is always nonsense.)

Page 387

Incidentally, here we must make a distinction between different sorts of question, a distinction which will show once again that what we call a "question" in mathematics is not the same as what we call by that name in everyday life. We must distinguish between the question "how does one divide an angle into two equal parts?" and the question "is *this* construction the bisection of an angle?" A question makes sense only in a calculus which gives us a method for its solution; and a calculus may well give us a method for answering the one question without giving us a method for answering the other. For instance, Euclid doesn't shew us how to look for the solutions to his problems; he gives them to us and then proves that they are solutions. And this isn't a psychological or pedagogical matter, but a mathematical one. That is, the *calculus* (the one he gives us) doesn't enable us to look for the construction. A calculus which does enable us to do that is a *different* one.

Page Break 388

(Compare methods of integration with methods of differentiation, etc.)

Page 388

In mathematics there are very different things that all get called proofs, and the differences between them are *logical* differences. The things called 'proofs' have no more internal connection with each other than the things called '*numbers*'.

What kind of *proposition* is "It is impossible to trisect an angle with ruler and compass"? The same kind, no doubt, as "There is no $F(3)$ in the series of angle-divisions $F(n)$, just as there is no 4 in the series of combination-numbers $[n.(n - 1)]/2$ ". But what kind of proposition is *that*? The same kind as "there is no $\frac{1}{2}$ in the series of cardinal numbers". That is obviously a (superfluous) rule of the game, something like: in draughts there is no piece that is called "the queen". The question whether trisection is possible is then the question whether there is such a thing in the game as trisection, whether there is a piece in draughts called "the queen" that has some kind of a role like that of the queen in chess. Of course this question could be answered simply by a stipulation; but it wouldn't set any problem or task of calculation, and so it wouldn't have the same sense as a question whose answer was: I will work out whether there is such a thing. (Something like: I will work out whether any of the numbers 5, 7, 18, 25 is divisible by 3). Now is the question about the possibility of trisecting an angle that sort of question? It is if you have a general system in the calculus for calculating the possibility of division into n equal parts.

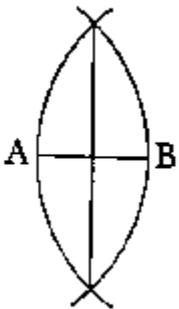

Now why does one call *this* proof the proof of *this* proposition? A proposition isn't a name; as a proposition it belongs to a system of language. If I can say "there is no such thing as trisection" then it makes sense to say "there is no such thing as quadrisection", etc., etc. And if *this* is a proof of the first proposition (a part of its syntax), then there must be corresponding proofs (or disproofs) for the other propositions of the proposition-system, otherwise they don't belong to the same system.

I can't ask whether 4 occurs among the combination-numbers

if that is my number-system. And I can't ask whether $\frac{1}{2}$ occurs in the cardinal numbers, or show that it isn't one of them, unless by "cardinal numbers" I mean part of a system that contains $\frac{1}{2}$ as well. (Equally I can't either say or prove that 3 is one of the cardinal numbers.) The question really means something like this: "If you divide $\frac{1}{2}$ do you get whole numbers?", and that can only be asked in a system in which divisibility and indivisibility is familiar. (The *working out* must make sense.)

If we don't mean by "cardinal numbers" a subset of the rational numbers, then we can't work out whether $\frac{81}{3}$ is a cardinal number, but only whether the division $\frac{81}{3}$ comes out or not.

Instead of the problem of trisecting an angle with straightedge and compass we might investigate a parallel, and much more perspicuous problem. There is nothing to prevent us restricting the possibilities of construction with straightedge and compass still further. We might for instance lay down the condition that the angle of the compass may not be changed. And we might lay down that the only construction we know--or better: that our calculus knows--is the one used to bisect a line AB, namely

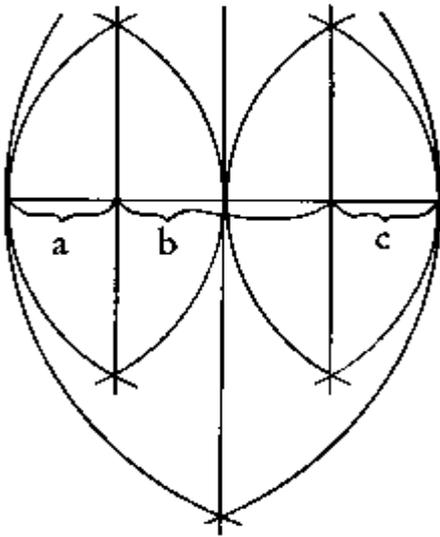

(That might actually be the primitive geometry of a tribe. I said above that the number series "1, 2, 3, 4, 5, many" has equal rights with the series of cardinal numbers†1 and that would go for this geometry too. In general it is a good dodge in our investigations to imagine the arithmetic or geometry of a primitive people.)

I will call this geometry the system α and ask: "in the system α is it possible to trisect a line?"

What kind of trisection is meant in this question?--that's obviously what the sense of the question depends on. For instance, is what is meant physical trisection--trisection, that is, by trial and error and measurement? In that case the answer is perhaps yes. Or optical trisection--trisection, that is, which yields three parts which look the same

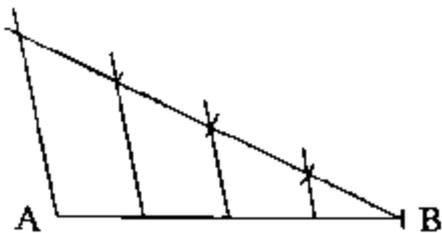

length? It is quite easily imaginable that the parts a, b, and c might look the same length if, for instance, we were looking through some distorting medium.

Page 390

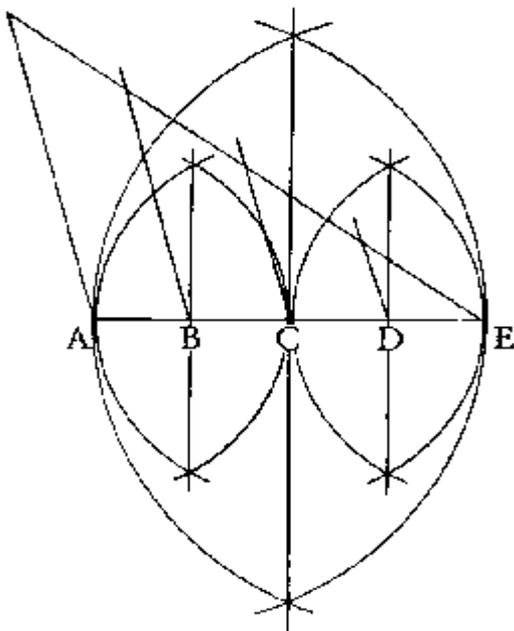

We might represent the results of division in the system α by the numbers $2, 2^2, 2^3$, etc. in accordance with the number of the segments produced; and the question whether trisection is possible might mean: does any of the numbers in this series = 3? Of course that question can only be asked if $2, 2^2, 2^3$, etc. are imbedded in another system (say the cardinal number system); it can't be asked if these numbers are themselves our number system for in that case we, or our system, are not acquainted with the number 3. But if our question is: is one of the numbers $2, 2^2$, etc. equal to 3, then here nothing is really said about a *trisection* of the line. None the less, we might look in this manner at the question about the possibility of trisection.--We get a different view, if we adjoin to the system α a system in which lines are divided in the manner of this figure:

Page Break 391

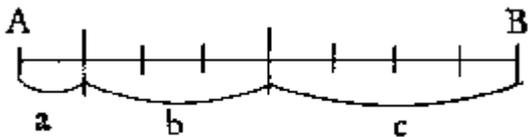

Page 391

It can then be asked: is a division into 180 sections a division of type α ? And this question might again boil down to: is 108 a power of 2? But it might also indicate a different decision procedure (have a different sense) if we connected the systems α and β to a system of geometrical constructions in such a way that it could be proved in the system that the two constructions "must yield" the same division points B, C, D.

Page 391

Suppose that someone, having divided a line AB into 8 sections in the system α , groups these into the lines a, b, c, and asks: is that a trisection into 3 equal sections? (We could make the case more easily imaginable if we took a larger number of original sections,

Page Break 392

which would make it possible to form groups of sections which looked the same length). The answer to that question would be a proof that 2^3 is not divisible by 3; or an indication that the sections are in the ratio 1:3:4. And now you might ask: but surely I do have a concept of trisection in the system, a concept of a division which yields the parts a, b, c, in the ratio 1:1:1? Certainly, I have now introduced a new concept of 'trisection of a line'; we might well say that by dividing the line AB into eight parts we have divided the line CB into 3 equal parts, if that is just *to mean* we have produced a line that consists of 3 equal parts.

Page 392

The perplexity in which we found ourselves in relation to the problem of trisection was roughly this: if the trisection of an angle is impossible--logically impossible--how can we ask questions about it at all? How can we describe what is logically impossible and significantly raise the question of its possibility? That is, how can one put together *logically* ill-assorted concepts (in violation of grammar, and therefore nonsensically) and significantly ask about the possibility of the combination?--But the same paradox would arise if we asked "is $25 \times 25 = 620$?"; for after all it's *logically* impossible that that equation should be correct; I certainly can't describe what it would be like if...--Well, a doubt whether $25 \times 25 = 620$ (or whether it = 625) has no more and no less sense than the method of checking gives it. It is quite correct that we don't here imagine, or describe, what it is like for 25×25 to be 620; what that means is that we are dealing with a type of question that is (logically) different from "is this street 620 or 625 metres long"?

Page 392

(We talk about a "division of a circle into 7 segments" and also of a division of a cake into 7 segments).

Page Break 393

Page 393

If you say to someone who has never tried "try to move your ears", he will first move some part of his body near his ears that he has moved before, and either his ears will move at once or they won't. You might say of this process: he is trying to move his ears. But if it can be called trying, it isn't trying in at all the same sense as trying to move your ears (or your hands) in a case where you already "know how to do it" but someone is holding them so that you can move them only with difficulty or not at all. It is the first sense of trying that corresponds to trying "to solve a mathematical problem" when there is no method for its solution. One can always ponder on the apparent problem. If someone says to me "try by sheer will power to move that jug at the other end of the room" I will look at it and perhaps make some strange movements with my face muscles; so that even in that case there seems to be such a thing as trying.

Page 393

Think of what it means to *search for* something in one's memory. Here there is certainly *something like* a search in the strict sense.

Page 393

But trying to produce a phenomenon is not the same as *searching* for it.

Page 393

Suppose I am feeling for a painful place with my hand. I am searching in touch-space not in pain-space. That means: what I find, if I find it, is really a place and not the pain. That means that even if experience shows that pressing produces a pain, pressing isn't searching for a pain, any more than turning the handle of a generator is searching for a spark.

Page Break 394

Page 394

Can one try to beat the wrong time to a melody? How does such an attempt compare with trying to lift a weight that is too heavy?

Page 394

It is highly significant that one can see the group |||| in different ways (in different groupings); but what is still more noteworthy is that one can do it at will. That is, that there is a quite definite process of producing a particular "view" at will; and correspondingly a quite definite process of unsuccessfully attempting to do so. Similarly, you can to order see the figure below in such a way that first one and then the other vertical line is the nose, and first one and then the other line becomes the mouth; in certain circumstances you can try in vain to do the one or the other.

Page 394

The essential thing here is that this attempt is the same kind of thing as trying to lift a weight with the hand; is isn't like the sort of trying where one does different things, tries out different means, in order (e.g.) to lift a weight. In the two cases the word "attempt" has quite different meanings. (An extremely significant grammatical fact.)

Page Break 395

VI INDUCTIVE PROOFS AND PERIODICITY

29

How far is a proof by induction a proof of a proposition?

Page 395

If a proof by induction is a proof of $a + (b + c) = (a + b) + c$, we must be able to say: *the calculation gives the result* that $a + (b + c) = (a + b) + c$ (and no other result).

Page 395

In that case the general method of calculating it must already be known, and we must be able to work out $a + (b + c)$ straight off in the way we can work out 25×16 . So first there is a general rule taught for working out all such problems, and later the particular cases are worked out.--But what is the general method of working out here? It must be based on general rules for signs (--say, the associative law--).

Page 395

If I negate $a + (b + c) = (a + b) + c$ it only makes sense if I mean to say something like: $a + (b + c)$ isn't $(a + b) + c$, but $(a + 2b) + c$. For the question is: In what space do I negate the proposition? If I mark it off and exclude it, what do I exclude it from?

Page 395

To check $25 \times 25 = 625$ I work out 25×25 until I get the right hand side;--can I work out $a + (b + c) = (a + b) + c$, and get the result $(a + b) + c$? Whether it is provable or not depends on whether we treat it as calculable or not. For if the proposition is a rule, a paradigm, which every calculation has to follow, then it makes no more sense to talk of working out the equation, than to talk of working out a definition.

Page 395

What makes the calculation possible is the system to which the proposition belongs; and that also determines what miscalculations can be made in the working out. E.g. $(a + b)^2$ is $a^2 + 2ab + b^2$ and not $a^2 + ab + b^2$; but $(a + b)^2 = -4$ is not a possible miscalculation in this system.

Page Break 396

Page 396

I might also say very roughly (see other remarks): " $25 \times 64 = 160, 64 \times 25 = 160$; that proves that $a \times b = b \times a$ " (this way of speaking need not be absurd or incorrect; you only have to interpret it correctly). The conclusion can be correctly drawn from that; so in *one* sense " $a.b = b.a$ " can be proved.

Page 396

And I want to say: It is *only* in the sense in which you can call working out such an example a proof of the algebraic proposition that the proof by induction is a proof of the proposition. Only to that extent is it a check of the algebraic proposition. (It is a check of its structure, not its generality).

Page 396

(Philosophy does not examine the calculi of mathematics, but only what mathematicians say about these calculi.)

Page Break 397

Recursive proof and the concept of proposition. Is the proof a proof that a proposition is true and its contradictory false?

Page 397

Is the recursive proof of

$$a + (b + c) = (a + b) + c \dots A$$

an answer to a question? If so, what question? Is it a proof that an assertion is true and its contradictory false?

Page 397

What Skolem†1 calls a recursive proof of A can be written thus;

$$\left. \begin{aligned} \mathbf{a} + (\mathbf{b} + \mathbf{1}) &= (\mathbf{a} + \mathbf{b}) + \mathbf{1} \\ \mathbf{a} + (\mathbf{b} + (\mathbf{c} + \mathbf{1})) &= \mathbf{a} + ((\mathbf{b} + \mathbf{c}) + \mathbf{1}) = (\mathbf{a} + (\mathbf{b} + \mathbf{c})) + \mathbf{1} \\ (\mathbf{a} + \mathbf{b}) + (\mathbf{c} + \mathbf{1}) &= ((\mathbf{a} + \mathbf{b}) + \mathbf{c}) + \mathbf{1} \end{aligned} \right\} \mathbf{B}$$

Page 397

In this proof the proposition proved obviously doesn't occur at all.--What we have to do is to make a general stipulation permitting the step to it. This stipulation could be expressed thus

$$\left. \begin{aligned} \alpha \quad \varphi(\mathbf{1}) &= \psi(\mathbf{1}) \\ \beta \quad \varphi(\mathbf{c} + \mathbf{1}) &= F(\varphi(\mathbf{c})) \\ \gamma \quad \psi(\mathbf{c} + \mathbf{1}) &= F(\psi(\mathbf{c})) \end{aligned} \right\} \Delta \quad \varphi(\mathbf{c}) = \psi(\mathbf{c})$$

Page 397

If three equations of the form α, β, γ are proved, we say "the equation Δ is proved for all cardinal numbers". This is a definition of this latter form of expression in terms of the first. It shows that we aren't using the word "prove" in the second case in the same way as in the first. In any case it is misleading to say that we have proved the equation Δ or A. Perhaps it is better to say that we have proved its generality, though that too is misleading in other respects.

Page 397

Now has the proof B answered a question, or proved an assertion true? And which is the proof B? Is it the

group of three equations of the form α, β, γ or the class of proofs of these equations? These equations do *assert* something (they don't prove anything in the sense in which *they* are proved). But the proofs

Page Break 398

of α, β, γ answer the question whether these three equations are correct and prove true the assertion that they are correct. All I can do is to explain: the question whether A holds for all cardinal numbers is to mean: "for the functions

$$\phi(\xi) = a + (b + \xi), \psi(\xi) = (a + b) + \xi$$

are the equations α, β, γ valid?" And then that question is answered by the recursive proof of A, if what that means is the proofs of α, β, γ (or the laying down of α and the use of it to prove β and γ).

Page 398

So I can say that the recursive proof shows that the equation A satisfies a certain condition; but it isn't the kind of condition that the equation $(a + b)^2 = a^2 + 2ab + b^2$ has to fulfil in order to be called "correct". If I call A "correct" because equations of the form α, β, γ can be proved for it, I am no longer using the word "correct" in the same way as in the case of the equations α, β, γ or $(a + b)^2 = a^2 + 2ab + b^2$.

Page 398

$$\underline{1}/\underline{3} = \underline{0}\cdot\underline{3}$$

What does " $\underline{1}/\underline{3} = \underline{0}\cdot\underline{3}$ " mean? Does it mean the same as " $\underline{1}$..."?--Or is that division the proof of the first proposition? That is, does it have the same relationship to it as a calculation has to what is proved?

" $\underline{1}/\underline{3} = \underline{0}\cdot\underline{3}$ " is not the same kind of thing as

$$"1/2 = 0 \cdot 5";$$

$$\underline{1}/\underline{2} = \underline{0}\cdot\underline{5}$$

$$\underline{1}/\underline{3} = \underline{0}\cdot\underline{3}$$

what " $\underline{0}$... " corresponds to is " $\underline{1}$... " not

$$\underline{1}/\underline{3} = \underline{0}\cdot\underline{3}$$

" $\underline{1}$... "†1

Page 398

Instead of the notation " $1/4 = 0 \cdot 25$ " I will adopt for this occasion the following " $\underline{1}/\underline{4} = \underline{0}\cdot\underline{25}$ " So, for

example, " $\underline{3}/\underline{8} = \underline{0}\cdot\underline{375}$ ". Then I can say, what corresponds to this proposition is not

Page Break 399

$$\underline{1}/\underline{3} = \underline{0}\cdot\underline{333} \dots \underline{0}\cdot\underline{3}$$

$\underline{1}/\underline{3} = \underline{0}\cdot\underline{3}$, but e.g. " $\underline{1}$... " is not a result of division (quotient) in the same sense as $0 \cdot 375$. For we were acquainted with the numeral " $0 \cdot 375$ " before the division $3/8$; but what does " $\underline{0}\cdot\underline{3}$ " mean when detached from

the periodic division?--The assertion that the division $a:b$ gives $0.\underline{c}$ as quotient is the same as the assertion that the first place of the quotient is c and the first remainder is the same as the dividend.

Page 399

The relation of B to the assertion that A holds for all cardinal numbers is the same as that of

$$\underline{1}/\underline{3} = \underline{0}\cdot\underline{3} \text{ to } \underline{1}/\underline{3} = \underline{0}\cdot\underline{3}$$

Page 399

The contradictory of the assertion "A holds for all cardinal numbers" is: one of the equations α, β, γ is false. And the corresponding question isn't asking for a decision between $\forall x.fx$ and $\exists x.\sim fx$.

Page 399

The construction of the induction is not a proof, but a certain arrangement of proofs (a pattern in the sense of an ornament). And one can't exactly say either: if I prove three equations, then I prove one. Just as the movements of a suite don't amount to a single movement.

Page 399

We can also say: we have a rule for constructing, in a certain game, decimal fractions consisting only of 3's; but if you regard *this rule* as a kind of number, it can't be the result of a division; the only result would be what we

$$a/d = c$$

may call periodic division which has the form a .

Page Break 400

31

Induction. (x).φx and (∃x).φx. Does the induction prove the general proposition true and an existential proposition false?

Page 400

$$3 \times 2 = 5 + 1$$

$$3 \times (a + 1) = 3 + (3 \times a) = (5 + b) + 3 = 5 + (b + 3)$$

Page 400

Why do you call this induction the proof that $(n):n > 2 \supset 3 \times n \neq 5$? Well, don't you see that if the proposition holds for $n = 2$, it also holds for $n = 3$, and then also for $n = 4$, and that it goes on like that for ever? (What am I explaining when I explain the way a proof by induction works?) So you call it a proof of $f(2).f(3).f(4)$, etc." but isn't it rather the form of the proofs of " $f(2)$ " and " $f(3)$ " and " $f(4)$ ", etc.? Or does that come *to the same thing*? Well, if I call the induction the proof of *one* proposition, I can do so only if that is supposed to mean no more than that it proves every proposition of a certain form. (And my expression relies on the analogy with the relationship between the proposition "all acids turn litmus paper red" and the proposition "sulphuric acid turns litmus paper red").

Page 400

Suppose someone says "let us check whether $f(n)$ holds for all n " and begins to write the series

$$3 \times 2 = 5 + 1$$

$$3 \times (2 + 1) = (3 \times 2) + 3 = (5 + 1) + 3 = 5 + (1 + 3)$$

$$3 \times (2 + 2) = (3 \times (2 + 1)) + 3 = (5 + (1 + 3)) + 3 = 5 + ((1 + 3) + 3)$$

and then he breaks off and says "I see it holds for all n "--So he has seen an *induction*! But was he *looking for* an induction? He didn't have any method for looking for one. And if he hadn't discovered one, would he *ipso facto* have found a number which does not satisfy the condition?--The rule for checking can't be: let's see whether there is an induction or a case for which the law does not hold.--If the law of excluded middle doesn't hold, that can only mean that our expression isn't comparable to a proposition.

Page 400

When we say that the induction proves the general proposition, we think: it proves that this proposition and not its contradictory

Page Break 401

is true. But what would be the contradictory of the proposition proved? Well, that $(\exists n).\sim f(n)$ is the case. Here we combine two concepts: one derived from my current concept of the proof of $(n).f(n)$, and another taken from the analogy with $(\exists x).\phi x$. (Of course we have to remember that " $(n). f(n)$ " isn't a proposition until I have a criterion for its truth; and then it only has the sense that the criterion gives it. Although, before getting the criterion, I could look out for something like an analogy to $(x).fx \dagger 1$). What is the opposite of what the induction proves? The proof of $(a + b)^2 = a^2 + 2ab + b^2$ works out this equation in contrast to something like $(a + b)^2 = a^2 + 3ab + b^2$. What does the inductive proof work out? The equations: $3 \times 2 = 5 + 1$, $3 \times (a + 1) = (3 \times a) + 3$, $(5 + b) + 3 = 5 + (b + 3)$ as opposed to things like $3 \times 2 = 5 + 6$, $3 \times (a + 1) = (4 \times a) + 2$, etc. But this opposite does not correspond to the proposition $(\exists x).\phi x$ --Further, what does conflict with the induction is every proposition of the form $\sim f(n)$, i.e. the propositions " $\sim f(2)$ ", " $\sim f(3)$ ", etc.; that is to say, the induction is *the common element* in the working out of $f(2)$, $f(3)$, etc.; but it isn't the working out of "all propositions of the form $f(n)$ ", since of course no class of propositions occurs in the proof that I call "all propositions of the form $f(n)$ ". Each one of these calculations is a checking of a proposition of the form $f(n)$. I was able to investigate the correctness of this proposition and employ a method to check it; all the induction did was to bring this into a simple form. But if I call the induction "the proof of a general proposition", I can't ask whether that proposition is correct (any more than whether the form of the cardinal numbers is correct). Because the things I call inductive proofs give me no method of *checking* whether the general proposition is correct or incorrect; instead, the method has to show me how to work out (check) whether or not an induction can be constructed for a particular case within a system of propositions. (If I may so put it, what is checked in this way is whether all n have this or that property; not whether all of them have it, or whether there are some that don't have it.

For example, we work

Page Break 402

out that the equation $x^2 + 3x + 1 = 0$ has no rational roots (that there is no rational number that...), and the equation $x^2 + 2x + \frac{1}{2} = 0$ has none, but the equation $x^2 + 2x + 1 = 0$ does, etc.)

Page 402

Hence we find it odd if we are told that the induction is a proof of the general proposition; for we feel rightly that in the language of the induction we couldn't have posed the general question at all. It wasn't that we began with an alternative between which we had to decide. (We only seemed to, so long as we had in mind a calculus with finite classes).

Page 402

Prior to the proof asking about the general proposition made no sense at all, and so wasn't even a question, because the question would only have made sense if a general method of decision had been known *before* the particular proof was discovered.

Page 402

The proof by induction isn't something that settles a disputed question.

Page 402

If you say: "the proposition '(n).fn' follows from the induction" only means that every proposition of the form f(n) follows from the induction and "the proposition $(\exists n).\sim fn$ contradicts the induction" only means "every proposition of the form $\sim f(n)$ is disproved by the induction", then we may agree; but we shall ask: what is the correct way for us to use the expression "the proposition (n).f(n)"? What is its grammar? (For from the fact that I use it in certain contexts it doesn't follow that I use it everywhere in the same way as the expression "the proposition (x). ϕx .")

Page 402

Suppose that people argued whether the quotient of the division $1/3$ must contain only threes, but had no

$$\begin{array}{r} 1.0/3 \\ \mathbf{I} \end{array}$$

method of deciding it. Suppose one of them noticed the inductive property of $\mathbf{I} = 0.3$ and said: now I know that there must be only threes in the quotient. The others had not thought of *that* kind of decision. I suppose that they had vaguely imagined some kind of decision by checking each step, though of course they could never have reached a decision in this way. If they hold on to their extensional

Page Break 403

viewpoint, the induction does produce a decision because in the case of each extension of the quotient it shows that it consists of nothing but threes. But if they drop their extensional viewpoint the induction decides nothing, or

$$\begin{array}{r} 1.0/3 \\ \mathbf{I} \end{array}$$

nothing that is not decided by working out $\mathbf{I} = 0 \cdot 3$, namely that the remainder is the same as the dividend. But nothing else. Certainly, there is a valid question that may arise, namely, is the remainder left after this division the same as the dividend? This question now takes the place of the old extensional question, and of course I can keep the old wording, but it is now extremely misleading since it always makes it look as if having the induction were only a vehicle--a vehicle that can take us into infinity. (This is also connected with the fact that the sign "etc." refers to an internal property of the bit of the series that precedes it, and not to its extension.)

Page 403

Of course the question "is there a rational number that is a root of $x^2 \times 3x + 1 = 0$?" is decided by an induction; but in this case I have actually constructed a method of forming inductions; and the question is only so phrased because it is a matter of constructing inductions. That is, a question is settled by an induction, if I can look for the induction in advance; if everything in its sign is settled in advance bar my acceptance or rejection of it in such a way that I can decide yes or no by calculating; as I can decide, for instance, whether in $5/7$ the remainder is equal to the dividend or not. (The employment in these cases of the expressions "all..." and "there is..." has a certain similarity with the employment of the word "infinite" in the sentence "today I bought a straightedge with an infinite radius of curvature").

Page 403

$$\begin{array}{r} 1/3 \\ \mathbf{I} \end{array}$$

The periodicity of \mathbf{I} decides nothing that had been left open. Suppose someone had been looking in vain, before the discovery of the periodicity, for a 4 in the development of $1/3$, he

still couldn't significantly have put the question "is there a 4 in the development of 1/3?". That is, *independently of* the fact that he didn't actually discover any 4s, we can convince him that he doesn't have a method of deciding his question. Or we might say: quite apart from the result of his activity we could instruct him about the grammar of his question and the nature of his search (as we might instruct a contemporary mathematician about analogous problems). "But as a result of discovering the periodicity he does stop looking for a 4! So it does convince him that he will never find one."--No. The discovery of the periodicity will cure him of looking *if* he makes the appropriate adjustment. We might ask him: "Well, how about it, do you still want to look for a 4?" (Or has the periodicity so to say, changed your mind?)

The discovery of the periodicity is really the construction of a new symbol and a new calculus. For it is misleading to say that it consists in our having *realised* that the first remainder is the same as the dividend. For if we had asked someone unacquainted with periodic division whether the first remainder in this division was the same as the dividend, of course he would have answered "yes"; and so he did realise. But that doesn't mean he must have

$$a/b = c$$

realised the periodicity; that is, it wouldn't mean he had discovered the calculus with the sign **a** .

Isn't what I am saying what Kant meant, by saying that $5 + 7 = 12$ is not analytic but synthetic *a priori*?

Is there a further step from writing the recursive proof to the generalization? Doesn't the recursion schema already say all that is to be said?

We commonly say that the recursive proofs show that the algebraic equations hold for all cardinal numbers; for the time being it doesn't matter whether this expression is well or ill chosen, the point is whether it has the same clearly defined meaning in all cases.

And isn't it clear that the recursive proofs in fact show *the same* for all "proved" equations?

And doesn't that mean that between the recursive proof and the proposition it proves there is always the same (internal) relation?

Anyway it is quite clear that there must be a recursive, or better, iterative "proof" of this kind (A proof conveying the insight that "that's the way it must be with all the numbers".)

I.e. it seems clear *to me*; and it seems that by a process of iteration I could make the correctness of these theorems for the cardinal numbers intelligible to someone else.

But how do I know that $28 + (45 + 17) = (28 + 45) + 17$ without having proved it? How can a general proof give me a particular proof? I might after all go through the particular proof, and how would the two proofs meet in it? What happens if they do not agree?

In other words: suppose I wanted to show someone that the associative law is really part of the nature of number, and isn't something that only accidentally holds in this particular case; wouldn't I use a process of iteration to try to show that the law holds and must go on holding? Well--that shows us what we mean here by saying that a law must hold for all numbers.

And what is to prevent us calling this process a proof of the law?

This concept of "making something comprehensible" is a boon in a case like this.

For we might say: the criterion of whether something is a proof of a proposition is whether it could be used for making it comprehensible. (Of course here again all that is involved is an extension of our grammatical

investigation of the word "proof" and not any psychological interest in the process of making things comprehensible.)

Page 406

"This proposition is proved for all numbers by the recursive procedure." That is the expression that is so very misleading. It sounds as if here a proposition saying that such and such holds for all cardinal numbers is proved true by a particular route, and as if this route was a route through a space of conceivable routes.

Page 406

But really the recursion shows nothing but itself, just as periodicity too shows nothing but itself.

Page 406

We are not saying that when $f(1)$ holds and when $f(c + 1)$ follows from $f(c)$, the proposition $f(x)$ is *therefore* true of all cardinal numbers; but: "the proposition $f(x)$ holds for all cardinal numbers" *means* "it holds for $x = 1$, and $f(c + 1)$ follows from $f(c)$ ".

Page 406

Here the connection with generality in finite domains is quite clear, for in a finite domain that would certainly be a proof that $f(x)$ holds for all values of x , and *that* is the reason why we say in the arithmetical case that $f(x)$ holds for all numbers.

Page 406

At least I have to say that any objection that holds against the proof $B \dagger 1$ holds also e.g. against the formula $(a + b)^n = \text{etc.}$

Page 406

Here too, I would have to say, I am merely assuming an algebraic rule that agrees with the inductions of arithmetic.

Page Break 407

$$\begin{aligned} f(n) \times (a + b) &= f(n + 1) \\ f(1) &= a + b \\ \text{therefore } f(1) \times (a + b) &= (a + b)^2 = f(2) \\ \text{therefore } f(2) \times (a + b) &= (a + b)^3 = f(3), \text{ etc.} \end{aligned}$$

Page 407

So far all is clear. But then: "*therefore* $(a + b)^n = f(n)$ "!

Page 407

Is a further inference drawn here? Is there still something to be established?

Page 407

But if someone shows me the formula $(a + b)^n = f(n)$ I could ask: how have we got there? And the answer would be the group

$$\begin{aligned} f(n) \times (a + b) &= f(n + 1) \\ f(1) &= a + b \end{aligned}$$

So isn't it a proof of the algebraic proposition?--Or is it rather an answer to the question "what does the algebraic proposition mean?"

Page 407

I want to say: once you've got the induction, it's all over.

Page 407

The proposition that A holds for all cardinal numbers is really the complex B plus its proof, the proof of β and γ . But that shows that this proposition is not a proposition in the same sense as an equation, and this proof is not in the same sense a proof of a proposition.

Page 407

Don't forget that it isn't that we first of all have the concept of proposition, and then come to know that equations are mathematical propositions, and later realise that there are also other kinds of mathematical propositions.

Page Break 408

Page 408

(Editor's note: What follows between the square brackets we have taken from one of the manuscript books that Wittgenstein used for this chapter; although it is not in the typescript--"A" and "B" are given above, on p. 397.)

$$\begin{array}{l}
 \text{[(R)} \\
 \text{(I)} \\
 \left. \begin{array}{l}
 a + (b + (c + 1)) \stackrel{R}{=} a + ((b + c) + 1) = \\
 (a + b) + (c + 1) \stackrel{R}{=} ((a + b) + c) + 1
 \end{array} \right\} a + (b + c) = (a + b) + c \\
 \\
 \text{(II)} \\
 \left. \begin{array}{l}
 (a + 1) + 1 \stackrel{R}{=} (a + 1) + 1 \\
 1 + (a + 1) \stackrel{R}{=} (1 + a) + 1
 \end{array} \right\} a + 1 = 1 + a \\
 \\
 \text{(III)} \\
 \left. \begin{array}{l}
 a + (b + 1) \stackrel{R}{=} (a + b) + 1 \\
 (b + 1) + a \stackrel{R}{=} (b + (1 + a)) \stackrel{M}{=} b + (a + 1) \stackrel{R}{=} \\
 \qquad \qquad \qquad = (b + a) + 1
 \end{array} \right\} a + b = b + a \\
 \\
 \begin{array}{l}
 a \cdot 1 = a \dots \text{(D)} \\
 a \cdot (b + 1) = a \cdot b + a \text{(M)}
 \end{array} \\
 \\
 \text{(IV)} \\
 \left. \begin{array}{l}
 a \cdot (b + (c + 1)) \stackrel{R}{=} a \cdot ((b + c) + 1) \stackrel{M}{=} \\
 \qquad \qquad \qquad = a \cdot (b + c) + a \\
 a \cdot b + (a \cdot (c + 1)) \stackrel{M}{=} a \cdot b + (a \cdot c + a) \stackrel{M}{=} \\
 \qquad \qquad \qquad = (a \cdot b + a \cdot c) + a
 \end{array} \right\} a \cdot (b + c) = a \cdot b + a \cdot c
 \end{array}$$

Page 408

(A step by step investigation of this proof would be very instructive.) The first step in I, $a + (b + (c + 1)) = a + ((b + c) + 1)$, if it is made in accordance with R, shows that the variables in R are not meant in the same way as those in the equations of I; since R would otherwise allow only the replacement of $a + (b + 1)$ by $(a + b) + 1$, and not the replacement of $b + (c + 1)$ by $(b + c) + 1$.

Page Break 409

The same appears in the other steps in the proof.

Page 409

If I said that the proof of the two lines of the proof justifies me in inferring the rule $a + (b + c) = (a + b) + c$, that wouldn't mean anything, unless I had deduced that in accordance with a previously established rule. But this rule could only be

$$\left. \begin{array}{l}
 F_1(1) = F_2(1), F_1(x + 1) = f\{F_1(x)\} \\
 F_2(x + 1) = f\{F_2(x)\}
 \end{array} \right\} F_1(x) = F_2(x) \dots (\rho).$$

Page 409

But this rule is vague in respect of F_1 , F_2 and f .]

Page 409

We cannot appoint a calculation to be a proof of a proposition.

Page 409

I would like to say: Do we *have to* call the recursive calculation the proof of proposition I? That is, won't another relationship do?

Page 409

(What is infinitely difficult is to "see all round" the calculus.)

Page 409

In the one case "The step is justified" means that it can be carried out in accordance with definite forms that have been given. In the other case the justification might be that the step is taken in accordance with paradigms that themselves satisfy a certain condition.

Page 409

Suppose that for a certain board game rules are given containing only words with no "r" in them, and that I call a rule justified, if it contains no "r". Suppose someone then said, he had laid down only *one* rule for a certain game, namely, that its moves must obey rules containing no "r"s. Is that a rule of the game (in the first sense)? Isn't

the game played in accordance with the class of rules all of which have only to satisfy the first rule?

Page 409

Someone shows me the construction of B and then says that A has been proved. I ask "How? All I see is that you have used $\alpha[\rho]$ to build a construction around A". Then he says "But when that is

Page Break 410

possible, I say that A is proved". To that I answer: "That only shows me the new sense you attach to the word 'prove'."

Page 410

In one sense it means that you have used $\alpha[\rho]$ to construct the paradigm in such and such a way, in another, it means as before that an equation is in accordance with the paradigm.

Page 410

If we ask "is that a proof or not?" we are keeping to the word-language.

Page 410

Of course there can be no objection if someone says: if the terms of a step in a construction are of such and such a kind, I say that the legitimacy of the step is proved.

Page 410

What is it in me that resists the idea of B as a proof of A? In the first place I observe that in my calculation I now here use the proposition about "all cardinal numbers". I used ρ to construct the complex B and then I took the step to the equation A; in all that there was no mention of "all cardinal numbers". (This proposition is a bit of word-language accompanying the calculation, and can only mislead me.) But it isn't only that this general proposition completely drops out, it is that no other takes its place.

Page 410

So the proposition asserting the generalisation drops out; "nothing is *proved*", "nothing *follows*".

Page 410

"But the equation A follows, it is that that takes the place of the general proposition." Well, to what extent does it follow? Obviously, I'm here using "follows" in a sense quite different from the normal one, because what A follows from isn't a proposition. And that is why we feel that the word "follows" isn't being correctly applied.

Page 410

If you say "it follows from the complex B that $a + (b + c) = (a + b) + c$ ", we feel giddy. We feel that somehow or other you've said something nonsensical although outwardly it sounds correct.

Page Break 411

Page 411

That an equation follows, already has a meaning (has its own definite grammar).

Page 411

If I am told "A follows from B", I want to ask: "*what* follows?" That $a + (b + c)$ is equal to $(a + b) + c$, is something postulated, if it doesn't follow in the normal way from an equation.

Page 411

We can't fit our concept of following from to A and B; it doesn't fit.

Page 411

"I will prove to you that $a + (b + n) = (a + b) + n$." No one then expects to see the complex B. You expect to hear another rule for a, b, and n permitting the passage from one side to the other. If instead of that I am given B with the schema $\rho \dagger 1$ I can't call it a proof, because I mean something else by "proof".

Page 411

I shall very likely say something like "oh, so that's what you call a 'proof', I had imagined..."

Page 411

The proof of $17 + (18 + 5) = (17 + 18) + 5$ is certainly carried out in accordance with the schema B, and this numerical proposition is of the form A. Or again: B is a proof of the numerical proposition: but for that very reason, it isn't a proof of A.

Page 411

"I will derive A_I, A_{II}, A_{III} from a single proposition."†2--This

Page Break 412

of course makes one think of a derivation that *makes use* of these propositions--We think we shall be given smaller links of some kind to replace all these large ones in the chain.

Here we have a definite picture; and we are offered something quite different.

The inductive proof puts the equation together as it were crossways instead of lengthways.

If we work out the derivation, we finally come to the point at which the construction of B is completed. But at this point we say "therefore this equation holds"! But these words now don't mean the same as they do when we elsewhere deduce an equation from equations. The words "The equation follows from it" already have a meaning. And although an equation is constructed here, it is by a different principle.

If I say "the equation follows from the complex", then here an equation is 'following' from something that is not an equation.

We can't say: if the equation follows from B, then it does follow from a proposition, namely from $\alpha.\beta.\gamma$; for what matters is *how* I get A from that proposition; whether I do so in accordance with a rule of inference; and what the relationship is between the equation and the proposition $\alpha.\beta.\gamma$. (The rule leading to A in this case makes a kind of cross-section through $\alpha.\beta.\gamma$; it doesn't view the proposition in the same way as a rule of inference does.)

If we have been promised a derivation of A from α and now see the step from B to A, we feel like saying "oh, that isn't what was meant". It is as if someone had promised to give me something and then says: see, I'm giving you my trust.

The fact that the step from B to A is not an inference indicates also what I meant when I said that the logical product $\alpha.\beta.\gamma$ does not express the generalization.

I say that A_I, A_{II} etc. are used in proving $(a + b)^2 = \text{etc.}$ because the steps from $(a + b)^2$ to $a^2 + 2ab + b^2$ are all of the form A_I or A_{II} , etc. In this sense the step in III from $(b + 1) + a$ to $(b + a) + 1$ is also made in accordance with A_I , but the step from $a + n$ to $n + a$ isn't!

The fact that we say "*the correctness* of the equation is proved" shows that not every construction of the equation is a proof.

Someone shows me the complexes B and I say "they are not proofs of the equations A". Then he says: "You still haven't seen the system on which the complexes are constructed", and points it out to me. How could that make the Bs into proofs?

This insight makes me ascend to another, a higher, level; whereas a *proof* would have to be carried out on the lower level.

Nothing except a definite transition to an equation from other equations is a proof of that equation. Here there is no such thing, and nothing else can do anything to make B into a proof of A.

But can't I say that if I have proved this *about* A, I have thereby proved A? Wherever did I get the illusion that by doing this I had proved it? There must surely be some deep reason for this.

Well, if it is an illusion, at all events it arose from our expression in word-language "this proposition holds for *all* numbers"; for on this view the algebraic proposition is only another way of writing the proposition of word-language. And that form of expression caused us to confuse the case of *all* the numbers with the case of 'all the people in this room'. (What we do to distinguish the cases is to ask: how does one verify the one and the other?)

If I suppose the functions ϕ, ψ, F exactly defined and then write the schema for the inductive proof:

So when we said above we could begin with R, this beginning with R is in a way a piece of humbug. It isn't like beginning a calculation by working out 526×718 . For in the latter case setting out the problem is the first step on the journey to the solution. But in the former case I immediately drop the R and have to begin again somewhere else. And when it turns out that I construct a complex of the form R, it is again immaterial whether I explicitly set it out earlier, since setting it out hasn't helped me at all mathematically, i.e. in the calculus. So what is left is just the fact that I now have a complex of the form R in front of me.

We might imagine we were acquainted only with the proof B_I and could then say: all we have is this construction--no mention of an analogy between this and other constructions, or of a general principle in carrying out the constructions.--If I then see B and A like this I'm bound to ask: but why do you call that a proof of A precisely?--(I am not asking: why do you call it a *proof* of A)! What has this complex to do with A_I ? Any reply will have to make me aware of the relation between A and B which is expressed in V.†1

Someone shows us B, and explains to us the relationship with A_I , that is, that the right side of A was obtained in such and such a manner etc. etc. We understand him; and he asks us: is that a proof of A? We would answer: certainly *not*!

Had we understood everything there was to understand about the proof? Had we seen the general form of the connection between A and B? Yes!

We might also infer from that that in this way we can construct a B from every A and *therefore conversely an A from every B as well*.

The proof is constructed on a definite plan (a plan used to construct other proofs as well). But this plan cannot make the proof a proof. For all we have here is one of the embodiments of the plan, and we can altogether disregard the plan as a general concept. The proof has to speak for itself and the plan is only embodied in it, it isn't itself a constituent part of the proof. (That is what I've been wanting to say all the time). Hence it's no use to me if someone draws my attention to the similarity between proofs in order to convince me that they are proofs.

Isn't our principle: not to use a *concept-word* where one isn't necessary?--That means, in cases where the concept word really stands for an enumeration, to say so.

When I said earlier "that isn't a proof" I meant 'proof' in an already established sense according to which it can be gathered from A and B by themselves. In this sense I can say: I understand perfectly well what B does and what relationship it has to A; all further information is superfluous and what is there isn't a proof. In this sense I am concerned only with A and B; I don't see anything beyond them, and nothing else concerns me.

If I do this, I can see clearly enough the relationship in accordance with the rule V, but it doesn't enter my head to use it as an expedient in construction. If someone told me while I was considering B and A that there is a rule according to which we could have constructed B from A (or conversely), I could only say to him "don't bother me with irrelevant trivialities." Because of course it's something that's obvious, and I see immediately that it doesn't make B a proof of A. For the general rule couldn't shew that B is a proof of A *and not of some other proposition*, unless it were

a proof in the first place. That means, that the fact that the connection between B and A is in accordance with a rule can't show that B is a *proof* of A. Any and every such connection could be used as a construction of B from A (and conversely).

So when I said "R certainly isn't used for the construction, so we have no concern with it" I should have said: I am only concerned with A and B. It is enough if I confront A and B with each other and ask: "is B a proof of A?" So I don't need to construct A from B according to a previously established rule; it is sufficient for me to place the particular As--however many there are--in confrontation with particular Bs. I don't need a previously established

construction rule (a rule needed to obtain the As).

Page 418

What I mean is: in Skolem's calculus we don't *need* any such concept, the list is *sufficient*.

Page 418

Nothing is lost if instead of saying "we have proved the fundamental laws A in this fashion" we merely show that we can coordinate with them constructions that resemble them in certain respects.

Page 418

The concept of generality (and of recursion) used in these proofs has no greater generality than can be read immediately from the proofs.

Page 418

The bracket } in R, which unites α , β , and $\gamma \dagger 1$ can't mean any more than that we regard the step in A (or a step of the form A) as justified

Page Break 419

if the terms (sides) of the steps are related to each other in the ways characterized by the schema B. B then takes the place of A. And just as before we said: the step is permitted in my calculus if it corresponds to one of the As, so we now say: it is permitted if it corresponds to one of the Bs.

Page 419

But that wouldn't mean we had gained any simplification or reduction.

Page 419

We are given the calculus of equations. In that calculus "proof" has a fixed meaning. If I now call the inductive calculation a proof, it isn't a proof that saves me checking whether the steps in the chain of equations have been taken in accordance with *these* particular rules (or paradigms). If they have been, I say that the last equation of the chain is proved, or that the chain of equations is correct.

Page 419

Suppose that we were using the first method to check the calculation $(a + b)^3 = \dots$ and at the first step someone said: "yes, that step was certainly taken in accordance with $a(b + c) = a.b + a.c$, but is *that* right?" And then we showed him the inductive derivation of that equation.--

Page 419

The question "Is the equation G right? $\dagger 1$ " means in one meaning: can it be derived in accordance with the paradigms?--In the other case it means: can the equations α , β , γ be derived in accordance with the paradigm (or the paradigms?)--And here we have put the two meanings of the question (or of the word "proof") on the same level (expressed them in a single system) and can now compare them (and see that they are not the same).

Page 419

And indeed the new proof doesn't give you what you might expect: it doesn't base the calculus on a smaller foundation--as happens if we replace $p \vee q$ and $\sim p$ by $p|q$, or reduce the number of axioms, or something similar. For if we now say that all the basic equations A have been derived from ρ alone, the word "derived" here means something quite different. (After this promise we expect

Page Break 420

the big links in the chain to be replaced by smaller ones, not by two half links. $\dagger 1$) And in one sense these derivations leave everything as it was. For in the new calculus the links of the old one essentially continue to exist as links. The old structure is *not* taken to pieces. So that we have to say the proof goes on in the same way as before. And in the *old* sense the irreducibility remains.

Page 420

So we can't say that Skolem has put the algebraic system on to a smaller foundation, for he hasn't 'given it foundations' in the same sense as is used in algebra.

Page 420

In the inductive proof doesn't α show a connection between the As? And doesn't this show that we are here concerned with proofs?--The connection shown is not the one that breaking up the A steps into ρ steps would establish. And *one* connection between the As is already visible before any proof.

Page 420

I can write the rule R like *this*

$$\left. \begin{array}{l} \mathbf{a} + (\mathbf{1} + \mathbf{1}) = (\mathbf{a} + \mathbf{1}) + \mathbf{1} \\ \mathbf{a} + (\boldsymbol{\xi} + \mathbf{1}) = (\mathbf{a} + \boldsymbol{\xi}) + \mathbf{1} \\ \mathbf{a} + ((\boldsymbol{\xi} + \mathbf{1}) + \mathbf{1}) = (\mathbf{a} + (\boldsymbol{\xi} + \mathbf{1})) + \mathbf{1} \end{array} \right\} \mathbf{S}$$

or like this

$$\mathbf{a} + (\mathbf{b} + \mathbf{1}) = (\mathbf{a} + \mathbf{b}) + \mathbf{1}$$

if I take R or S as a definition or substitute for that form†2.

Page 420

Page Break 421

Page 421

If I then say that the steps in accordance with the rule R are justified thus:

$$\left. \begin{array}{l} \boldsymbol{\alpha} \quad \mathbf{a} + (\mathbf{b} + \mathbf{1}) = (\mathbf{a} + \mathbf{b}) + \mathbf{1} \\ \boldsymbol{\beta} \quad \mathbf{a} + (\mathbf{b} + (\mathbf{c} + \mathbf{1})) = \mathbf{a} + ((\mathbf{b} + \mathbf{c}) + \mathbf{1}) = (\mathbf{a} + (\mathbf{b} + \mathbf{c})) + \mathbf{1} \\ \boldsymbol{\gamma} \quad (\mathbf{a} + \mathbf{b}) + (\mathbf{c} + \mathbf{1}) = ((\mathbf{a} + \mathbf{b}) + \mathbf{c}) + \mathbf{1} \end{array} \right\} \mathbf{B}$$

you can reply: "If that's what you call a justification, then you have justified the steps. But you haven't told us any more than if you had just drawn our attention to the rule R and its formal relationship to α (or to α , β , and γ)."

Page 421

So I might also have said: I take the rule R in such and such a way as a paradigm for my steps.

Page 421

Suppose now that Skolem, following his proof of the associative law, takes the step to:

$$\left. \begin{array}{l} \mathbf{a} + \mathbf{1} = \mathbf{1} + \mathbf{a} \\ \mathbf{a} + (\mathbf{b} + \mathbf{1}) = (\mathbf{a} + \mathbf{b}) + \mathbf{1} \\ (\mathbf{b} + \mathbf{1}) + \mathbf{a} = \mathbf{b} + (\mathbf{1} + \mathbf{a}) = \mathbf{b} + (\mathbf{a} + \mathbf{1}) = (\mathbf{b} + \mathbf{a}) + \mathbf{1} \end{array} \right\} \mathbf{C}$$

If he says the first and third steps in the third line are justified according to the already proved associative law, that tells us no more than if he said the steps were taken in accordance with the paradigm $\mathbf{a} + (\mathbf{b} + \mathbf{c}) = (\mathbf{a} + \mathbf{b}) + \mathbf{c}$ (i.e. they correspond to the paradigm) and a schema α, β, γ was derived by steps according to the paradigm α .--"But does B justify these steps, or not?"--"What do you mean by the word 'justify'?--"Well, the step is

Page Break 422

justified if a theorem really has been proved that holds for all numbers"--But in what case would that have happened? What do you call a proof that a theorem holds for all cardinal numbers? How do you know whether a theorem is really valid for all cardinal numbers, since you can't test it? Your *only* criterion is the proof itself. So you *stipulate* a form and call it the form of the proof that a proposition holds for all cardinal numbers. In that case we really gain nothing by being first shown the general form of these proofs; for that doesn't show that the individual proof really gives us what we want from it; because, I mean, it doesn't justify the proof or demonstrate that it is a proof of a theorem for all cardinal numbers. Instead, the recursive proof has to be its own justification. If we really want to justify our proof procedure as a proof of a generalisation of this kind, we do something different: we give a series of examples and then we are satisfied by the examples and the law we recognize in them, and we say: yes our proof really gives us what we want. But we must remember that by giving this series of examples we have only translated the notations B and C into a different notation. (For the series of examples is not an incomplete application of the general form, but another expression of the law.) An explanation in word-language of the proof (of what it proves) only translates the proof into another form of expression: because of this we can drop the explanation altogether. And if we do so, the mathematical relationships become much clearer, no longer obscured by the equivocal expressions of word-language. For example, if I put B right beside A, without interposing any expression of word-language like "for all cardinal numbers, etc." then the misleading appearance of a proof of A by B cannot arise. We then see quite soberly how far the relationships between B and A and $\mathbf{a} + \mathbf{b} = \mathbf{b} + \mathbf{a}$ extend and where they stop. Only thus do we learn the real structure and important features of that relationship, and escape the confusion caused by the form of word-language, which makes everything uniform.

Here we see first and foremost that we are interested in the tree

of the structures B, C, etc., and that in it is visible on all sides, like a particular kind of branching, the following form

$$\phi(1) = \psi(1)$$

$$\phi(n + 1) = F(\phi n)$$

$$\psi(n + 1) = F(\psi n)$$

These forms turn up in different arrangements and combinations but they are not elements of the construction in the same sense as the paradigms in the proof of $(a + (b + (c + 1))) = (a + (b + c)) + 1$ or $(a + b)^2 = a^2 + 2ab + b^2$. The aim of the "recursive proofs" is of course to connect the algebraic calculus with the calculus of numbers. And the tree of the recursive proofs doesn't "justify" the algebraic calculus unless that is supposed to mean that it connects it with the arithmetical one. It doesn't justify it in the sense in which the list of paradigms justifies the algebraic calculus, i.e. the steps in it.

So tabulating the paradigms for the steps makes sense in the cases where we are interested in showing that such and such transformations are all made by means of those transition forms, arbitrarily chosen as they are. But it doesn't make sense where the calculation is to be justified in another sense, where mere looking at the calculation--independently of any comparison with a table of previously established norms--must shew us whether we are to allow it or not. Skolem did not have to promise us any proof of the associative and commutative laws; he could simply have said he would show us a connection between the paradigms of algebra and the calculation rules of arithmetic. But isn't this hair-splitting? Hasn't he reduced the number of paradigms? Hasn't he, for instance, replaced very pair of laws with a single one, namely, $a + (b + 1) = (a + b) + 1$? No. When we prove e.g. $(a + b)^4 = \text{etc.}$ (k) we can while doing so make use of the previously proved proposition $(a + b)^2 = \text{etc.}$ (l). But in that case the steps in k which are justified by l can also be justified by the rules used to prove l. And then the relation of l to those first rules is the same as that of a sign introduced by definition to the primary signs used to define it: we can always eliminate the definitions and go back to the primary signs. But when we take a step in C that is justified by B,

we can't take the same step with $a + (b + 1) = (a + b) + 1$ alone. What is called proof here doesn't break a step in to smaller steps but does something quite different.

The recursive proof does not reduce the number of fundamental laws

So here we don't have a case where a group of fundamental laws is proved by a smaller set while everything else in the proofs remains the same. (Similarly in a system of fundamental concepts nothing is altered in the later development if we use definitions to reduce the number of fundamental concepts.)

(Incidentally, how very dubious is the analogy between "fundamental laws" and "fundamental concepts"!)

It is something like this: all that the proof of a *ci-devant* fundamental proposition does is to continue the system of proofs backwards. But the recursive proofs don't continue backwards the system of algebraic proofs (with the old fundamental laws); they are a new system, that seems only to run parallel with the first one.

It is a strange observation that in the inductive proofs the irreducibility (independence) of the fundamental rules must show itself after the proof no less than before. Suppose we said the same thing about the case of normal proofs (or definitions), where fundamental rules *are* further reduced, and a new relationship between them is discovered (or constructed).

If I am right that the independence remains intact after the recursive proof, that sums up everything I have to say against the concept of recursive "proof".

The inductive proof doesn't break up the step in A. Isn't it that that makes me baulk at calling it a proof? It's that that tempts me to say that whatever it does--even if it is constructed by R and α --it can't do more than show something *about* the step.

If we imagine a mechanism constructed from cogwheels made simply out of uniform wedges held together by a ring, it is still the cogwheels that remain in a certain sense the units of the mechanism.

It is like this: if the barrel is made of hoops and wattles, it is these, combined as they are (as a complex) that hold the liquid and form new units as containers.

Imagine a chain consisting of links which can each be replaced by two smaller ones. Anything which is anchored by the chain can also be anchored entirely by the small links instead of by the large ones. But we might also imagine every link in the chain being made of two parts, each perhaps shaped like half a ring, which together formed a link, but could not individually be used as links.

Then it wouldn't mean at all the same to say, on the one hand: the anchoring done by the large links can be done entirely by small links--and on the other hand: the anchoring can be done entirely by half large links. What is the difference?

One proof replaces a chain with large links by a chain with small links, the other shows how one can put together the old large links from several parts.

The similarity as well as the difference between the two cases is obvious.

Of course the comparison between the proof and the chain is a logical comparison and therefore a completely exact expression of what it illustrates.

Recurring decimals

$$1/3 = 0.\dot{3}$$

We regard the periodicity of a fraction, e.g. of 1/3 as consisting in the fact that something called the extension of the infinite decimal contains only threes; we regard the fact that in this division the remainder is the same as the dividend as a mere *symptom* of this property of the infinite extension. Or else we correct this view by saying that it isn't an infinite extension that has this property, but an infinite series of finite extensions; and it is *of this* that the property of the division is a symptom. We may then say: the extension taken to *one* term is 0.3, to two terms 0.33, to three terms 0.333 and so on. That is a *rule* and the "and so on" refers to the regularity; the rule might also be

$$1/3 = 0.3$$

written " $0.3, 0.\xi, 0.\xi3$ " But what is proved by the division $1/3 = 0.\dot{3}$ is *this* regularity in contrast to another, not

$$1/3 = 0.3$$

$$1/3 = 0.3$$

regularity in contrast to irregularity. The periodic division $1/3 = 0.\dot{3}$ (in contrast to $1/3 = 0.3$) proves a periodicity in the quotient, that is it *determines* the rule (the repetend), it lays it down; it isn't a symptom that a regularity is "already there". *Where* is it already? In things like the particular expansions that I have written on this paper. But they aren't "*the* expansions". (Here we are misled by the idea of unwritten ideal extensions, which are a phantasm like those ideal, undrawn, geometric straight lines of which the actual lines we draw are mere tracings.) When I said "the 'and so on' refers to the regularity" I was distinguishing it from the 'and so on' in "he read all the letters of the alphabet: a, b, c and so on". When I say "the extensions of 1/3 are 0.3, 0.33, 0.333 and so on" I give three *three*

$$1/3 = 0.3$$

extensions and--a rule. That is the only thing that is infinite, and only in the same way as the division $1/3 = 0.\dot{3}$

One can say of the sign $0.\dot{3}$ that it is not an abbreviation.

And the sign " $|0\cdot3, 0\cdot\xi, 0\cdot\xi3|$ " isn't a substitute for an extension, but the undevalued sign itself; and " $0.\dot{3}$ "

does just as well. It should give us food for thought, that a sign like " $0.\dot{3}$ " is *enough* to do what we need. It isn't a mere substitute in the calculus there are no substitutes.

Page 428

$$1/3 = 0.\dot{3}$$

If you think that the peculiar property of the division $\frac{1}{3}$ is a symptom of the periodicity of the infinite decimal fraction, or *the* decimal fractions of the expansion, it is indeed a sign that something *is* regular, but *what?* The extensions that I have constructed? But there aren't any others. It would be a most absurd manner of speaking to say: the property of the division is an indication that the result has the form " $|0\cdot a, 0\cdot\xi, 0\cdot\xi a|$ "; that is like

wanting to say that a division was an indication that the result was a number. The sign " $0.\dot{3}$ " does not express its meaning from any greater distance than " $0\cdot333\dots$ ", because this sign gives an extension of three terms and a rule; the extension $0\cdot333$ is inessential for our purposes and so there remains only the rule, which is given just as well by " $|0\cdot3, 0\cdot\xi, 0\cdot\xi3|$ ". The proposition "After the first place the division is periodic" just means "The first remainder is the same as the dividend". Or again: the proposition "After the first place the division will yield the same number to infinity", *means* "The first remainder is the same as the dividend", just as the proposition "This straightedge has an infinite radius" means it is straight.

Page 428

We might now say: the places of a quotient of $1/3$ are *necessarily*

Page Break 429

all 3s, and all that could mean would be again that the first remainder is like the dividend and the first place of the quotient is 3. The negation of the first proposition is therefore equivalent to the negation of the second. So the opposite of "necessarily all" isn't what one might call "accidentally all"; "necessarily all" is as it were one word. I only have to ask: what is the criterion of the necessary generalization, and what would be the criterion of the accidental generalization (the criterion for all numbers accidentally having the property ϵ)?

Page Break 430

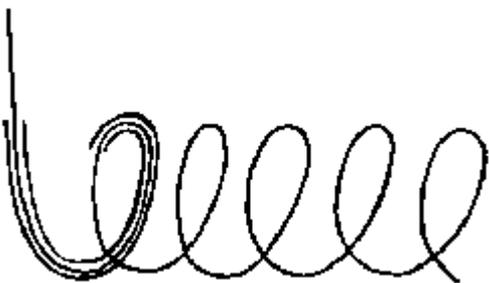

The recursive proof as a series of proofs

Page 430

A "recursive proof" is the general term of a series of proofs. So it is a law for the construction of proofs. To the question how this general form can save me the proof of a particular proposition, e.g. $7 + (8 + 9) = (7 + 8) + 9$, the answer is that it merely gets everything ready for the proof of the proposition, it doesn't prove it (indeed the proposition doesn't occur in it). The proof consists rather of the general form plus the proposition.

Page 430

Our normal mode of expression carries the seeds of confusion right into its foundations, because it uses the word "series" both in the sense of "extension", and in the sense of "law". The relationship of the two can be illustrated by a machine for making coiled springs, in which a wire is pushed through a *helically* shaped

passage to make as many coils as are desired. What is called an infinite helix need not be anything like a finite piece of wire, or something that that approaches the longer it becomes; it is the law of the helix, as it is embodied in the short passage. Hence the expression "infinite helix" or "infinite series" is misleading.

Page 430

So we can always write out the recursive proof as a limited series with "and so on" without its losing any of its rigour. At the same time this notation shows more clearly its relation to the equation A. For then the recursive proof no longer looks at all like a justification of A in the sense of an algebraic proof--like the proof

of $(a + b)^2 = a^2 + 2ab + b^2$. That proof with algebraic calculation rules is quite like calculation with numbers.

$$\begin{aligned} 5 + (4 + 3) &= 5 + (4 + (2 + 1)) = 5 + ((4 + 2) + 1) = \\ &= (5 + (4 + 2)) + 1 = (5 + (4 + (1 + 1))) + 1 = \\ &= (5 + ((4 + 1) + 1)) + 1 = ((5 + (4 + 1)) + 1) + 1 = \\ &= (((5 + 4) + 1) + 1) + 1 = ((5 + 4) + 2) + 1 = (5 + 4) + 3 \dots (L) \end{aligned}$$

Page 431

That is a proof of $5 + (4 + 3) = (5 + 4) + 3$, but we can also let it count, i.e. use it, as a proof of $5 + (4 + 4) = (5 + 4) + 4$, etc.

Page 431

If I say that L is the proof of the proposition $a + (b + c) = (a + b) + c$, the oddness of the step from the proof to the proposition becomes much more obvious.

Page 431

Definitions merely introduce practical abbreviations; we could get along without them. But is that true of recursive definitions?

Page 431

Two different things might be called applications of the rule $a + (b + 1) = (a + b) + 1$: in one sense $4 + (2 + 1) = (4 + 2) + 1$ is an application, in another sense $4 + (2 + 1) = ((4 + 1) + 1) + 1 = (4 + 2) + 1$ is.

Page 431

The recursive definition is a rule for constructing replacement rules, or else the general term of a series of definitions. It is a signpost that shows the *same* way to all expressions of a certain form.

Page 431

As we said, we might write the inductive proof without using letters at all (with no loss of rigour). Then the recursive definition $a + (b + 1) = (a + b) + 1$ would have to be written as a series of definitions. As things are, this series is concealed in the explanation of its use. Of course we can keep the letters in the definition for the sake of convenience, but in that case in the explanation we have to bring in a sign like " $|1, (1) + 1, ((1) + 1) + 1$ and so on", or, what boils down to the same thing, " $|1, \xi, \xi + 1|$ ". But here we mustn't believe that this sign should really be " $(\xi).|1, \xi, \xi + 1|$ "!

Page 432

The point of our formulation is of course that the concept "all numbers" is given only by a structure like " $|1, \xi, \xi + 1|$ ". The generality is *set out* in the symbolism by this structure and cannot be *described* by an $(x).fx$.

Page 432

Of course the so-called "recursive definition" isn't a definition in the customary sense of the word, because it isn't an equation, since the equation " $a + (b + 1) = (a + b) + 1$ " is only a part of it. Nor is it a logical product of equations. Instead, it is a law for the construction of equations; just as $|1, \xi, \xi + 1|$ isn't a number but a law etc. (The bewildering thing about the proof of $a + (b + c) = (a + b) + c$ is of course that it's supposed to come out of the definition alone. But α isn't a definition, but a general rule for addition).

Page 432

$$1/3 = 0.3$$

On the other hand the generality of this rule is no different from that of the periodic division $1/3$. That means, there isn't anything that the rule leaves open or in need of completion or the like.

Page 432

Let us not forget: the sign " $|1, \xi, \xi + 1|$ "... N interests us not as a striking expression for the general term of the series of cardinal numbers, but only in so far as it is contrasted with signs of similar construction. *Nas opposed to* something like $|2, \xi, \xi + 3|$; in short, as a sign, or an instrument, in a calculus. And of course the same holds for $1/3 = 0.3$

1 . (The only thing left open in the rule is its application.)

$$\begin{aligned} 1 + (1 + 1) &= (1 + 1) + 1, \quad 2 + (1 + 1) = (2 + 1) + 1, \quad 3 + (1 + 1) = (3 + 1) + 1 \dots \text{and so on} \\ 1 + (2 + 1) &= (1 + 2) + 1, \quad 2 + (2 + 1) = (2 + 2) + 1, \quad 3 + (2 + 1) = (3 + 2) + 1 \dots \text{and so on} \\ 1 + (3 + 1) &= (1 + 3) + 1, \quad 2 + (3 + 1) = (2 + 3) + 1, \quad 3 + (3 + 1) = (3 + 3) + 1 \dots \text{and so on} \\ &\text{and so on.} \end{aligned}$$

We might write the rule " $a + (b + 1) = (a + b) + 1$ ", thus.†1

$$\left| \begin{array}{l} a + (1 + 1) = (a + 1) + 1 \\ \downarrow \qquad \qquad \downarrow \\ a + (\xi + 1) \quad (a + \xi) + 1 \\ a + ((\xi + 1) + 1) \quad ((a + \xi) + 1) + 1 \end{array} \right| \mathbf{R}$$

In the application of the rule R (and the description of the application is of course an inherent part of the sign for the rule), a ranges over the series $|1, \xi, \xi + 1|$; and of course that might be expressly stated by an additional sign, say " $a \rightarrow N$ ". (We might call the second and third lines of the rule R taken together the operation, like the second and third term of the sign N.) Thus too the explanation of the use of the recursive definition " $a + (b + 1) = (a + b) + 1$ " is a part of that rule itself; or if you like a repetition of the rule in another form; just as " $1, 1 + 1, 1 + 1 + 1$ and so on" means the *same* as (i.e. is translatable into) " $|1, \xi, \xi + 1|$ ". The translation into word-language *casts light on* the calculus with the new signs, because we have already mastered the calculus with the signs of word-language.

The sign of a rule, like any other sign, is a sign belonging to a calculus; its job isn't to hypnotize people into accepting an application, but to be used in the calculus in accordance with a system. Hence the exterior form is no more essential than that of an arrow \rightarrow ; what is essential is the system in which the sign for the rule is employed. The system of contraries--so to speak--from which the sign is distinguished etc.

What I am here calling the description of the application is itself of course something that contains an "and so on", and so it can itself be no more than a supplement to or substitute for the rule-sign.

What is the contradictory of a general proposition like $a + (b + (1 + 1)) = a + ((b + 1) + 1)$? What is the system of propositions within which this proposition is negated? Or again, how, and in what form, can this proposition come into contradiction with others? What question does it answer? Certainly not the question

whether $(n).fn$ or $(\exists n).\sim fn$ is the case, because it is the rule R that contributes to the generality of the proposition. The generality of a rule is *eo ipso* incapable of being brought into question.

Now imagine the general rule written as a series

- P11, P12, P13...
- P21, P22, P23...
- P31, P32, P33...
-

and then negated. If we regard it as $(x).fx$, then we are treating it as a logical product and its opposite is the logical sum of the denials of p_{11}, p_{12} etc. This disjunction can be combined with any random product $p_{11} \cdot p_{21} \cdot p_{22} \cdot \dots \cdot p_{mn}$. (Certainly if you compare the proposition with a logical product, it becomes infinitely significant and its opposite void of significance). (But remember that the "and so on" in the proposition comes after a comma, not after an "and" (",") The "and so on" is not a sign of *incompleteness*.)

Is the rule R infinitely significant? Like an enormously long logical product?

That one can run the number series though the rule is a form that is given; nothing is affirmed about it and nothing can be denied about it.

Running the stream of numbers through is not something which I can say I can prove. I can only prove something about the form, or pattern, through which I run the numbers.

But can't we say that the general number rule $a + (b + c) = (a + b) + c \dots A$ has the same generality as $a + (1 +$

1) = (a + 1) + 1 (in that the latter holds for every cardinal number and the former for every triple of cardinal numbers) and that the inductive proof of A justifies the rule A? Can we say that we can give the rule A, since the

$$\frac{1}{3} = 0.3$$

proof shows that it is always right? Does **I** justify the rule

$$\frac{1}{3} = 0.3, \frac{1}{3} = 0.333, \frac{1}{3} = 0.333 \dots \text{and so on?} \dots P)$$

A is a completely intelligible rule; just like the replacement rule P. But I can't give such a rule, for the reason that I can already

Page Break 435

calculate the particular instances of A by another rule; just as I cannot give P as a rule if I have given a rule whereby I

can calculate $\frac{1}{3} = 0.3$ etc.

Page 435

How would it be if someone wanted to lay down "25 × 25 = 625" as a rule in addition to the multiplication rules. (I don't say "25 × 25 = 624"!)-25 × 25 = 625 only makes sense if the kind of calculation to which the equation belongs is already known, and it only makes sense in connection with that calculation. A only makes sense in connection with A's own kind of calculation. For the first question here would be: is that a stipulation, or a derived proposition? If 25 × 25 = 625 is a stipulation, then the multiplication sign does not mean the same as it does, e.g. in reality (that is, we are dealing with a different kind of calculation). And if A is a stipulation, it doesn't define addition in the same way as if it is a derived proposition. For in that case the stipulation is of course a definition of the addition sign, and the rules of calculation that allow A to be worked out are a different definition of the same sign. Here I mustn't forget that α, β, γ isn't the proof of A, but only the form of the proof, or of what is proved; so α, β, γ is a definition of A.

Page 435

Hence I can only say "25 × 25 = 625 is proved" if the method of proof is fixed independently of the specific proof. For it is this method that settles the meaning of "ξ × η" and so settles what is proved. So to that extent the

$$\underline{a} \cdot \underline{b} = \underline{c}$$

form **a** belongs to the method of proof that explains the sense of c. Whether I have calculated correctly is another question. And similarly α, β, γ belong to the method of proof that defines the sense of the proposition A.

Page 435

Arithmetic is complete without a rule like A; without it it doesn't lack anything. The proposition A is introduced into arithmetic with the discovery of a periodicity, with the construction of a new calculus. Before this discovery or construction a question about the correctness of that proposition would have as little sense as a question about the correctness of "1/3 = 0.3, 1/3 = 0.33... ad inf."

Page Break 436

Page 436

The stipulation of P is not the same thing as the proposition "1/3 = 0.3" and in that sense "a + (b + **ċ**) = (a + b) + **ċ**" is different from a rule (stipulation) such as A. The two belong to different calculi. The proof of α, β, γ is a proof or justification of a rule like A only in so far as it is the general form of the proof of arithmetical propositions of the form A.

Page 436

Periodicity is not a sign (symptom) of a decimal's recurring; the expression "it goes on like that for ever" is only a translation of the sign for periodicity into another form of expression. (If there was something other than the periodic sign of which periodicity was only a symptom, that something would have to have a specific expression, which could be nothing less than the complete expression of that something.)

Page Break 437

Seeing or viewing a sign in a particular manner. Discovering an aspect of a mathematical expression. "Seeing an expression in a particular way". Marks of emphasis.

Page 437

Earlier I spoke of the use of connection lines, underlining etc. to bring out the corresponding, homologous, parts of

the equations of a recursion proof. In the proof

$$\begin{array}{l}
 a + (b + \overset{\gamma}{1}) = (a + b) + \overset{\alpha}{1} \\
 a + (b + (\underbrace{c + 1}_{\delta})) = (a + (b + c)) + \overset{\beta}{1} \\
 (a + b) + (\underbrace{c + 1}_{\xi}) = ((a + b) + c) + \overset{\epsilon}{1}
 \end{array}$$

the one marked α for example corresponds not to β but to c in the next equation; and β corresponds not to δ but to ϵ ; and γ not to δ but to $c + \delta$, etc.

Or in

$$\begin{array}{l}
 \overset{\alpha}{(a + 1)} + \overset{\beta}{1} = (\overset{\kappa}{a} + \overset{\lambda}{1}) + \overset{\zeta}{1} \\
 \overset{\gamma}{1} + (\overset{\delta}{a + 1}) = (\overset{\mu}{1} + \overset{\eta}{a}) + \overset{\theta}{1}
 \end{array}$$

ι doesn't correspond to κ and ϵ doesn't correspond to λ ; it is β that ι corresponds to; and β does not correspond to ξ , but ξ corresponds to θ and α to δ and β to γ and γ to μ , not to θ , and so on.

Page 437

What about a calculation like

$$(5 + 3)^2 = (5 + 3) \cdot (5 + 3) = 5 \cdot (5 + 3) + 3 \cdot (5 + 3) = 5 \cdot 5 + 5 \cdot 3 + 3 \cdot 5 + 3 \cdot 3 = 5^2 + 2 \cdot 5 \cdot 3 + 3^2 \dots R$$

from which we can also read a general rule for the squaring of a binomial?

Page 437

We can as it were look at this calculation arithmetically or algebraically.

Page Break 438

Page 438

This difference between the two ways of looking at it would have been brought out e.g. if the example had been written

$$(5 + 2)^2 = 5^2 + \overset{\alpha}{2} \cdot \overset{\beta}{2} \cdot 5 + \overset{\beta}{2}^2$$

In the algebraic way of looking at it we would have to distinguish the 2 in the position marked α from the 2s in the positions marked β but in the arithmetical one they would not need to be distinguished. We are--I believe--using a different calculus in each case.

Page 438

According to one but not the other way of looking at it the calculation above, for instance, would be a proof of $(7 + 8)^2 = 8^2 + 2 \cdot 7 \cdot 8 + 8^2$.

Page 438

We might work out an example to make sure that $(a + b)^2$ is equal to $a^2 + b^2 + 2ab$, not to $a^2 + b^2 + 3ab$ --if we had forgotten it for instance; but we couldn't check in that sense whether the formula holds *generally*. But of course there is *that sort of* check too, and in the calculation

$$(5 + 3)^2 = \dots = 5^2 + 2 \cdot 5 \cdot 3 + 3^2$$

I might check whether the 2 in the second summand is a general feature of the equation or something that depends

on the particular numbers occurring in the example.

I turn $(5 + 2)^2 = 5^2 + 2 \cdot 2 \cdot 5 + 2^2$ into another sign, if I write

$$\overset{\alpha}{(5 + 2)}^2 = \overset{\alpha}{5}^2 + \overset{\beta}{2} \cdot \overset{\alpha}{2} \cdot \overset{\beta}{5} + \overset{\beta}{2}^2$$

and thus "indicate which features of the right hand side originate from the particular numbers on the left" etc.

Page 438

(Now I realize the importance of this process of coordination. It expresses a new way of looking at the calculation and therefore a way of looking at a new calculation.)

Page 438

In order to prove A'--we could say--I first of all have to draw attention to quite definite features of B. (As in

$$1 \cdot 0 / 3 = 0 \cdot 3$$

the division $1 \quad \quad \quad$).

Page Break 439

Page 439

(And α had no suspicion, so to speak, of what I see if I do.)

Page 439

Here the relationship between generality and proof of generality is like the relationship between existence and proof of existence.

Page 439

When α, β, γ are proved, the general calculus has still to be discovered.

Page 439

Writing " $a + (b + c) = (a + b) + c$ " in the induction series seems to us a matter of course, because we don't see that by doing so we are starting a totally new calculus. (A child just learning to do sums would see dearer than we do in this connection.)

Page 439

Certain features are brought out by the schema R; they could be specially marked thus: $\dagger 1$

$$\overbrace{a + (b + 1)}^{f_1 (1)} = \overbrace{(a + b) + 1}^{f_2 (1)}$$

$$\overbrace{a + (b + (c + 1))}^{f_1 (c + 1)} = \overbrace{(a + (b + c)) + 1}^{f_1 (c) + 1}$$

$$\overbrace{(a + b) + (c + 1)}^{f_2 (c + 1)} = \overbrace{((a + b) + c) + 1}^{f_2 (c) + 1}$$

Of course it would also have: been enough (i.e. it would have been a symbol of the same multiplicity) if we had written B and added

$$f_1 \xi = a + (b + \xi), f_2 \xi = (a + b) + \xi$$

Page 439

(Here we must also remember that *every* symbol--however explicit--*can* be misunderstood.)

Page 439

The first person to draw attention to the fact that B can be seen in that way introduces a new sign whether or not he goes on to attach special marks to B or to write the schema R beside it. In

Page Break 440

the latter case R itself is the new sign, or, if you prefer, B plus R. It is the way in which he draws attention to it that produces the new sign.

Page 440

We might perhaps say that here the lower equation is used as $a + b = b + a$; or similarly that here B is used as A, by being as it were read sideways. Or: B was used as A, but the new proposition was built up from $\alpha.\beta.\gamma$, in such a way that though A is now read out of B, $\alpha.\beta.\gamma$ don't appear in the sort of abbreviation in which the premisses turn up in the conclusion.

Page 440

What does it mean to say: "I am drawing your attention to the fact that the same sign occurs here in both function signs (perhaps you didn't notice it)"? Does that mean that he didn't understand the proposition?--After all, what he didn't notice was something which belonged essentially to the proposition; it wasn't as if it was some external property of the proposition he hadn't noticed (Here again we see what kind of thing is called "understanding a proposition".)

Page 440

Of course the picture of reading a sign lengthways and sideways is once again a *logical* picture, and for that reason it is a perfectly exact expression of a grammatical relation. We mustn't say of it "it's a mere metaphor, who knows what the facts are really like?"

Page 440

When I said that the new sign with the marks of emphasis must have been derived from the old one without the marks, that was meaningless, because of course I can consider the sign with the marks without regard to its origin. In that case it presents itself to me as three equations [Frege]†1, that is as the shape of three equations with certain underlinings, etc.

Page Break 441

Page 441

It is certainly significant that this shape is quite similar to the three equations without the underlinings; it is also significant that the cardinal number 1 and the rational number 1 are governed by similar rules; but that does not prevent what we have here from being a new sign. What I am now doing with this sign is something quite new.

Page 441

Isn't this like the supposition I once made that people might have operated the Frege-Russell calculus of truth-functions with the signs "~" and "." combined into "~p.~q" without anyone noticing, and that Sheffer, instead of giving a new definition, had merely drawn attention to a property of the signs already in use.

Page 441

We might have gone on dividing without ever becoming aware of recurring decimals. When we have seen them, we have seen something new.

Page 441

But couldn't we extend that and say "I might have multiplied numbers together without ever noticing the special case in which I multiply a number by itself; and that means x^2 is not simply $x.x$ "? We might call the invention of the sign ' x^2 ' the expression of our having become aware of that special case. Or, we might have gone on

multiplying a by b and dividing it by c without noticing that we could write " $\frac{a.b}{c}$ " as " $a.(b|c)$ " or that the latter is similar to a.b. Or again, this is like a savage who doesn't yet see the analogy between |||| and |||||, or between || and |||||.

$$[a + (b + 1) \underline{\underline{\alpha}} (a + b) + 1] \& [a + (b + (c + 1)) \underline{\underline{\beta}} (a + (b + c)) + 1] \& [(a + b) + (c + 1) \underline{\underline{\gamma}} ((a + b) + c) + 1].$$

Def
 $\underline{\underline{=}} .a + (b + c).\exists.(a + b) + c... U)$

and in general:

$$[f_1(1) \underline{\underline{\rho}} f_2(1)] \& [f_1(c + 1) \underline{\underline{\beta}} f_1(c) + 1] \& [f_2(c + 1) \underline{\underline{\gamma}} = f_2(c) + 1]. \underline{\underline{Def}} .f_1(c).\exists.f_2(c)... V)$$

Page Break 442

Page 442

You might see the definition U, without knowing why I use that abbreviation.

Page 442

You might see the definition without understanding its point.--But its point is something new, not something already contained in it as a specific replacement rule.

Page 442

Of course, " \mathfrak{S} " isn't an equals-sign in the same sense as the ones occurring in α , β , γ .

Page 442

But we can easily show that " \mathfrak{S} " has certain formal properties in common with $=$.

Page 442

It would be incorrect--according to the postulated rules--to use the equals-sign like this:

$$\begin{aligned} \Delta \dots |(a + b)^2 = a.(a + b) + b.(a + b) = \dots = \\ = a^2 + 2ab + b^2|. = |(a + b)^2 = a^2 + 2ab + b^2| \end{aligned}$$

if that is supposed to mean that the left hand side is the proof of the right.

Page 442

But mightn't we imagine this equation regarded as a definition? For instance, if it had always been the custom to write out the whole chain instead of the right hand side, and we introduced the abbreviation.

Page 442

Of course Δ can be regarded as a definition! Because the sign on the left hand side is in fact used, and there's no reason why we shouldn't abbreviate it according to this convention. Only in that case either the sign on the right or the sign on the left is used in a way different from the one now usual.

Page 442

It can never be sufficiently emphasized that *totally different* kinds of sign-rules get written in the form of an equation.

Page 442

The 'definition' $x.x = x^2$ might be regarded as merely allowing us to replace the sign " $x.x$ " by the sign " x^2 ," like the definition " $1 + 1 = 2$ "; but it can also be regarded (and in fact is regarded) as allowing us to put a^2 instead of $a.a$, and $(a + b)^2$ instead of $(a + b).(a + b)$ and in such a way that any arbitrary number can be substituted for the x .

Page Break 443

Page 443

A person who discovers that a proposition p follows from one of the form $q \supset p.q$ constructs a new sign, the sign for that rule. (I am assuming that a calculus with p , q , \supset , has already been in use, and that this rule is now added to make it a new calculus.)

Page 443

It is true that the notation " x^2 " takes away the possibility of replacing one of the factors x by another number. Indeed, we could imagine two stages in the discovery (or construction) of x^2 . At first, people might have written " x =" instead of " x^2 ", before it occurred to them that there was a system $x.x$, $x.x.x$, etc.; later, they might have hit upon that too. Similar things have occurred in mathematics countless times. (In Liebig's sign for an oxide oxygen did not appear as an element in the same way as what was oxidized. Odd as it sounds, we might even today, with all the data available to us, give oxygen a similarly privileged position--only, of course, in the *form of representation*--by adopting an incredibly artificial interpretation, i.e. grammatical construction.)

Page 443

The definitions $x.x = x^2$, $x.x.x = x^3$ don't bring anything into the world except the signs " x^2 " and " x^3 " (and thus so far it isn't necessary to write numbers as exponents).

[The process of generalization creates a new sign-system.]

Page 443

Of course Sheffer's discovery is not the discovery of the definition $\sim p.\sim q = p|q$. Russell might well have given that definition without being in possession of Sheffer's system, and on the other hand Sheffer might have built up his system without the definition. His system is contained in the use of the signs " $\sim p.\sim p$ " for " $\sim p$ " and " $\sim(\sim p.\sim q).\sim(\sim p.\sim q)$ " for " $p \vee q$ " and all " $p|q$ " does is to permit an *abbreviation*. Indeed, we can say that someone could well have been acquainted with the use of the sign " $\sim(\sim p.\sim q).\sim(\sim p.\sim q)$ " for " $p \vee q$ " without recognizing the system $p|q$.| $p|q$ in it.

Page Break 444

Page 444

It makes matters clearer if we adopt Frege's two primitive signs " \sim " and " $.$ ". The discovery isn't lost if the definitions are written $\sim p.\sim p = \sim p$ and $\sim(\sim p.\sim p).\sim(\sim q.\sim q) = p.q$. Here apparently nothing at all has been altered in the original signs.

But we might also imagine someone's having written the whole Fregean or Russellian logic in this system, and yet, like Frege, calling "~" and "." his primitive signs, because he did not see the other system in his proposition.

It is clear that the discovery of Sheffer's system in $\sim.p.\sim p = \sim p$ and $\sim(\sim p.\sim p).\sim(\sim q.\sim q) = p.q$ corresponds to the discovery that $x^2 + ax + a^2/4$ is a specific instance of $a^2 + 2ab + b^2$.

We don't see that something can be looked at in a certain way until it is so looked at.

We don't see that an aspect is possible until it is there.

That sounds as if Sheffer's discovery wasn't capable of being represented in signs at all. (Periodic division.) But that is because we can't smuggle the *use* of the sign into its introduction (the rule is and remains a sign, separated from its application).

Of course I can only apply the general rule for the induction proof when I discover the substitution that makes it applicable. So it would be possible for someone to see the equations

$$(a + 1) + 1 = (a + 1) + 1$$

$$1 + (a + 1) = (1 + a) + 1$$

without hitting on the substitution

$$a = x, F_1(x) = x + 1, F_1(x + 1) = (x + 1) + 1,$$

$$F_2(x + 1) = 1 + (x + 1), F_2(x) = 1 + x$$

Moreover, if I say that I *understand* the equations as particular cases of the rule, my understanding has to be the understanding that shows itself in the explanations of the relations between the rule and the equations, i.e. what we express by the substitutions. If I don't regard that as an expression of what I understand, then nothing is an expression of it; but in that case it makes no sense either to speak of understanding or to say that I understand something definite. For it only makes sense to speak of understanding in cases where we understand *one* thing as opposed to another. And it is this contrast that signs express.

Indeed, seeing the internal relation must in its turn be seeing something that can be described, something of which one can say: "I see that such and such is the case"; it has to be really something of the same kind as the correlation-signs (like connecting lines, brackets, substitutions, etc.). Everything else has to be contained in the application of the sign of the general rule in a particular case.

It is as if we had a number of material objects and discovered they had surfaces which enabled them to be placed in a continuous row. Or rather, as if we discovered that such and such surfaces, which we had seen before, enabled them to be placed in a continuous row. That is the way many games and puzzles are solved.

The person who discovers periodicity invents a new calculus. The question is, how does the calculus with periodic division differ from the calculus in which periodicity is unknown?

(We might have operated a calculus with cubes without having had the idea of putting them together to make prisms.)

Appendix†1

(On: The process of generalization creates a new sign-system)

It is a very important observation that the c in A is not the same variable as the c in β and γ . So the way I wrote out the proof was not quite correct in a respect which is very important for us. In A we could substitute n for c , whereas the c s in β and γ are identical.

Page 446

But another question arises: can I derive from A that $i + (k + c) = (i + k) + c$? If so, why can't I derive it in the same way from B ? Does that mean that a and b in A are not identical with a and b in α , β and γ ?

Page 446

We see clearly that the variable c in B isn't identical with the c in A if we put a number instead of it. Then B is something like

$$\left. \begin{array}{l} \alpha \quad 4 + (5 + 1) = (4 + 5) + 1 \\ \beta \quad 4 + (5 + (6 + 1)) = (4 + (5 + 6)) + 1 \\ \gamma \quad (4 + 5) + (6 + 1) = ((4 + 5) + 6) + 1 \end{array} \right\} \dots W$$

but that doesn't have corresponding to it an equation like $A_W: 4 + (5 + 6) = (4 + 5) + 6!$

Page 446

What makes the induction proof different from a proof of A is expressed in the fact that the c in B is not identical with the one in A , so that we could use different letters in the two places.

Page 446

All that is meant by what I've written above is that the reason it looks like an algebraic proof of A is that we think we meet the same variables a , b , c in the equations A as in α , β , γ and so we

Page Break 447

regard A as the result of a transformation of those equations. (Whereas of course in reality I regard the signs α , β , γ in quite a different way, which means that the c in β and γ isn't used as a variable in the same way as a and b . Hence one can express this new view of B , by saying that the c does not occur in A .)

Page 447

What I said about the new way of regarding α , β , γ might be put like this: α is used to build up β and γ in exactly the same way as the fundamental algebraic equations are used to build up an equation like $(a + b)^2 = a^2 + 2ab + b^2$. But if that is the way they are derived, we are regarding the complex $\alpha \beta \gamma$ in a new way when we give the variable c a function which differs from that of a and b (c becomes the hole through which the stream of numbers has to flow).

Page Break 448

Proof by induction, arithmetic and algebra

Page 448

Why do we need the commutative law? Not so as to be able to write the equation $4 + 6 = 6 + 4$, because that equation is justified by its own particular proof. Certainly the proof of the commutative law can also be used to prove it, but in that case it becomes just a particular arithmetical proof. So the reason I need the law, is to apply it when using letters.

Page 448

And it is this justification that the inductive proof cannot give me.

Page 448

However, one thing is clear: if the recursive proof gives us the right to calculate algebraically, then so does the arithmetical proof $L \dagger 1$.

Page 448

Again: the recursive proof is--of course--essentially concerned with numbers. But what use are numbers to me when I want to operate purely algebraically? Or again, the recursion proof is only of use to me when I want to use it to justify a step in a number-calculation.

Page 448

But someone might ask: do we need *both* the inductive proof *and* the associative law, since the latter cannot provide a foundation for calculation with numbers, and the former cannot provide one for transformations in algebra?

Page 448

Well, before Skolem's proof was the associative law, for example, just accepted without anyone's being able

to work out the corresponding step in a numerical calculation? That is, were we previously unable to work out $5 + (4 + 3) = (5 + 4) + 3$, and did we treat it as an axiom?

Page 448

If I say that the periodic calculation proves the proposition that justifies me in those steps, what would the proposition have been

Page Break 449

like if it had been assumed as an axiom instead of being proved?

Page 449

What would a proposition be like that permitted one to put $5 + (7 + 9) = (5 + 7) + 9$ without being able to prove it? It is obvious that there never has been such a proposition.

Page 449

But couldn't we also say that the associative law isn't used at all in arithmetic and that we work only with particular number calculations?

Page 449

Even when algebra uses arithmetical notation, it is a *totally different* calculus, and cannot be derived from the arithmetical one.

Page 449

To the question "is $5 \times 4 = 20$ "? one might answer: "let's check whether it is in accord with the basic rules of arithmetic" and similarly I might say: let's check whether A is in accord with the basic rules. But with which rules? Presumably with α .

Page 449

But before we can bring α and A together we need to stipulate what we want to call "agreement" here.

Page 449

That means that α and A are separated by the gulf between arithmetic and algebra,†1 and if B is to count as a proof of A, this gulf has to be bridged over by a stipulation.

Page 449

It is quite clear that we do use an idea of this kind of agreement when, for instance, we quickly work out a numerical example to check the correctness of an algebraic proposition.

Page 449

And in this sense I might e.g. calculate

$$\begin{array}{r} 25 \times 16 \\ \hline 25 \\ 150 \\ \hline 400 \end{array} \quad \begin{array}{r} 16 \times 25 \\ \hline 32 \\ 80 \\ \hline 400 \end{array}$$

Page Break 450

and say: "yes, it's right, a.b is equal to b.a"--if I imagine that I have forgotten.

Page 450

Considered as a rule for algebraic calculation, A cannot be proved recursively. We would see that especially dearly if we wrote down the "recursive proof" as a series of arithmetical expressions. Imagine them written down (i.e. a fragment of the series plus "and so on") without any intention of "proving" anything, and then suppose someone asks: "does that prove $a + (b + c) = (a + b) + c$ ". We would ask in astonishment "How can it prove anything of the kind? The series contains only numbers, it doesn't contain any letters".--But no doubt we might say: if I introduce A as a rule for calculation with letters, that brings this calculus in a certain sense into unison with the calculus of the cardinal numbers, the calculus I established by the law for the rules of addition (the recursive definition $a + (b + 1) = (a + b) + 1$).

Page Break 451

VII INFINITY IN MATHEMATICS: THE EXTENSIONAL VIEWPOINT

"What is the sense of such a proposition as ' $(\exists n).3 + n = 7$ '?" Here we are in an odd difficulty: on the one hand we feel it to be a problem that the proposition has the choice between infinitely many values of n , and on the other hand the sense of the proposition seems guaranteed in itself and only needing further research on our part, because after all we "know 'what $(\exists x) \phi x$ ' means". If someone said he didn't know what was the sense of " $(\exists n).3 + n = 7$ ", he would be answered "but you do know what this proposition says: $3 + 0 = 7. \vee 3 + 1 = 7. \vee 3 + 2 = 7$ and so on!" But to that one can reply "Quite correct--so the proposition isn't a logical sum, because a logical sum doesn't end with 'and so on'. What I am not clear about is this propositional form ' $\phi(0) \vee \phi(1) \vee \phi(2) \vee$ and so on'--and all you have done is to substitute a second unintelligible kind of proposition for the first one, while pretending to give me something familiar, namely a disjunction."

That is, if we believe that we do understand " $(\exists n)$ etc." in some absolute sense, we have in mind as a justification other uses of the notation " $(\exists \dots)$...", or of the ordinary-language expression "There is..." But to that one can only say: So you are *comparing* the proposition " $(\exists n)$..." with the proposition "There is a house in this city which..." or "There are two foreign words on this page". But the occurrence of the words "there is" in those sentences doesn't suffice to determine the grammar of this generalization, all it does is to indicate a certain analogy in the rules. And so we can still investigate the grammar of the generalisation " $(\exists n)$ etc." with an open mind, that is, without letting the meaning of " $(\exists \dots)$..." in other cases get in our way.

"Perhaps all numbers have the property ε ". Again the question is:

what is the grammar of this general proposition? Our being acquainted with the use of the expression "all..." in other grammatical systems is not enough. If we say "you do know what it means: it means $\varepsilon(0).\varepsilon(1).\varepsilon(2)$ and so on", again nothing is explained except that the proposition is *not* a logical product. In order to understand the grammar of the proposition we ask: how is the proposition used? What is regarded as the criterion of its truth? What is its verification?--If there is no method provided for deciding whether the proposition is true or false, then it is pointless, and that means senseless. But then we delude ourselves that there is indeed a method of verification, a method which cannot be employed, but only because of human weakness. This verification consists in checking all the (infinitely many) terms of the product $\varepsilon(0).\varepsilon(1).\varepsilon(2)$... Here there is confusion between physical impossibility and what is called 'logical impossibility'. For we think we have given sense to the expression "checking of the infinite product" because we take the expression "infinitely many" for the designation of an enormously large number. And when we hear of "the impossibility of checking the infinite number of propositions" there comes before our mind the impossibility of checking a very large number of propositions, say when we don't have sufficient time.

Remember that in the sense in which it is impossible to check an infinite number of propositions it is also impossible to try to do so.--If we are using the words "But you do know what 'all' means" to appeal to the cases in which this mode of speech is used, we cannot regard it as a matter of indifference if we observe a distinction between these cases and the case for which the use of the words is to be explained.--Of course we know what is meant by "checking a number of propositions for correctness", and it is this understanding that we are appealing to when we claim that one should understand also the expression "... infinitely many propositions". But doesn't the sense of the first expression depend on the specific experiences that correspond to it? And these experiences are lacking in the employment (the calculus) of the second expression; if any experiences at all are correlated to it they are fundamentally different ones.

Ramsey once proposed to express the proposition that infinitely many objects satisfied a function $f(\xi)$ by the denial of all propositions like

$\sim(\exists x).fx$
 $(\exists x).fx.\sim(\exists x, y).fx.fy$
 $(\exists x, y).fx.fy.\sim(\exists x, y, z).fx.fy.fz$
 and so on.

But this denial would yield the series

$(\exists x).fx$

$(\exists x, y).fx.fy$
 $(\exists x, y, z)...., etc., etc.$

Page 453

But this series too is quite superfluous: for in the first place the last proposition at any point surely contains all the previous ones, and secondly even it is of no use to us, because it isn't about an infinite number of objects. So in reality the series boils down to the proposition:

" $(\exists x, y, z... \text{ ad inf.}).fx.fy.fz... \text{ ad inf.}$ "

and we can't make anything of that sign unless we know its grammar. But one thing is clear: what we are dealing with isn't a sign of the form " $(\exists x, y, z).fx.fy.fz$ " but a sign whose similarity to that looks purposely deceptive.

Page 453

I can certainly define " $m > n$ " as $(\exists x):m - n = x$, but by doing so I haven't in any way analysed it. You think, that by using the symbolism " $(\exists...)...$ " you establish a connection between " $m > n$ " and other propositions of the form "there is... "; what you forget is that that can't do more than stress a certain analogy, because the sign " $(\exists...)...$ " is used in countless many different 'games'. (Just as there is a 'king' in chess and draughts.) So we have to know the rules governing its use *here*; and as soon as we do that it immediately becomes clear that these rules are connected with the rules for subtraction. For if

Page Break 454

we ask the usual question "how do I know--i.e. where do I get it from--that there is a number x that satisfies the condition $m - n = x$?" it is the rules for subtraction that provide the answer. And then we see that we haven't gained very much by our definition. Indeed we might just as well have given as an explanation of ' $m > n$ ' the rules for checking a proposition of that kind--e.g. ' $32 > 17$ '.

Page 454

If I say: "given any n there is a δ for which the function is less than n ", I am *ipso facto* referring to a general arithmetical criterion that indicates when $F(\delta) < n$.

Page 454

If in the nature of the case I cannot write down a number independently of a number system, that must be reflected in the general treatment of number. A number system is not something inferior--like a Russian abacus--that is only of interest to elementary schools while a more lofty general discussion can afford to disregard it.

Page 454

Again, I don't lose anything of the generality of my account if I give the rules that determine the correctness and incorrectness (and thus the sense) of ' $m > n$ ' for a particular system like the decimal system. After all I need *a* system, and the generality is preserved by giving the rules according to which one system can be translated into another.

Page 454

A proof in mathematics is general if it is generally applicable. You can't demand some other kind of generality in the name of rigour. *Every* proof rests on *particular* signs, produced on a particular occasion. All that can happen is that one type of generality may appear more elegant than another. ((Cf. the employment of the decimal system in proofs concerning δ and η)).

Page 454

"Rigorous" means: clear.†1

Page Break 455

"We may imagine a mathematical proposition as a creature which itself knows whether it is true or false (in contrast with propositions of experience).

Page 455

A mathematical proposition itself knows that it is true or that it is false. If it is about all numbers, it must also survey all the numbers. "Its truth or falsity must be contained in it as is its sense."

Page 455

"It's as though the generality of a proposition like ' $(n).\varepsilon(n)$ ' were only a pointer to the genuine, actual, mathematical generality, and not the generality itself. As if the proposition formed a sign only in a purely external way and you still needed to give the sign a sense from within."

Page 455

"We feel the generality possessed by the mathematical assertion to be different from the generality of the proposition proved."

"We could say: a mathematical proposition is an allusion to a proof."†1

What would it be like if a proposition itself did not quite grasp its sense? As if it were, so to speak, too grand for itself? That is really what logicians suppose.

A proposition that deals with all numbers cannot be thought of as verified by an endless striding, for, if the striding is endless, it does not lead to any goal.

Imagine an infinitely long row of trees, and, so that we can inspect them, a path beside them. All right, the path must be endless. But if it is endless, then that means precisely that you can't walk to the end of it. That is, it does *not* put me in a position to survey the row. That is to say, the endless path does not have an end 'infinitely far away', it has no end.

Nor can you say: "A proposition cannot deal with all the numbers one by one, so it has to deal with them by means of the concept of number" as if this were a *pis aller*: "Because we can't do it like *this*, we have to do it another way." But it is indeed possible to deal with the numbers one by one, only that *doesn't*

lead to the totality. That *doesn't* lie on the path on which we go step by step, not even at the infinitely distant end of that path. (This all only means that " $\epsilon(0).\epsilon(1).\epsilon(2)$ and so on" is not the sign for a logical product.)

"It cannot be a contingent matter that all numbers possess a property; if they do so it must be essential to them."--The proposition "men who have red noses are good-natured" does not have the same sense as the proposition "men who drink wine are goodnatured" even if the men who have red noses are the same as the men who drink wine. On the other hand, if the numbers m, n, o are the extension of a mathematical concept, so that is the case that $f_m.f_n.f_o$, then the proposition that the numbers that satisfy f have the property ϵ has the same sense as " $\epsilon(m).\epsilon(n).\epsilon(o)$ ". This is because the propositions " $f(m).f(n).f(o)$ " and " $\epsilon(m).\epsilon(n).\epsilon(o)$ " can be transformed into each other without leaving the realm of grammar.

Now consider the proposition: "all the n numbers that satisfy the condition $F(\xi)$ happen by chance to have the property ϵ ". Here what matters is whether the condition $F(\xi)$ is a mathematical one. If it is, then I can indeed derive $\epsilon(x)$ from $F(x)$, if only via the disjunction of the n values of $F(\xi)$. (For what we have in this case is in fact a disjunction). So I won't call this chance.--On the other hand if the condition is a non-mathematical one, we can speak of chance. For example, if I say: all the numbers I saw today on buses happened to prime numbers. (But, of course, we can't say: the numbers 17, 3, 5, 31 happen to be prime numbers" any more than "the number 3 happens to be a prime number"), "By chance" is indeed the opposite of "in accordance with a general rule", but however odd it sounds one can say that the proposition "17, 3, 5, 31 are prime numbers" is derivable by a general rule just like the proposition $2 + 3 = 5$.

If we now return to the first proposition, we may ask again: How is the proposition "all numbers have the property ϵ " supposed to be meant? How is one supposed to be able to know? For to settle its sense you must settle that too! The expression "by chance" indicates a verification by successive tests, and that is contradicted by the fact that we are not speaking of a finite series of numbers.

In mathematics description and object are equivalent. "The fifth number of the number series has these properties" says *the same* as "5 has these properties". The properties of a house do not *follow* from its position in a row of houses; but the properties of a number are the properties of a position.

You might say that the properties of a particular number cannot be foreseen. You can only see them when you've got there.

What is general is the repetition of an operation. Each stage of the repetition has its own individuality. But it isn't as if I use the operation to move from one individual to another so that the operation would be the means for

getting from one to the other--like a vehicle stopping at every number which we can then study: no, applying the operation $+ 1$ three times yields and *is* the number 3.

Page 457

(In the calculus process and result are equivalent to each other.)

Page 457

But before deciding to speak of "all these individualities" or "the totality of these individualities" I had to consider carefully what stipulations I wanted to make here for the use of the expressions "all" and "totality".

Page 457

It is difficult to extricate yourself completely from the extensional viewpoint: You keep thinking "Yes, but there must still be an internal relation between $x^3 + y^3$ and z^3 since at least extensions of these expressions if I only knew them would have to show the result of such a relation". Or perhaps: "It must surely be either *essential* to *all* numbers to have the property or not, even if I can't know it."

Page Break 458

Page 458

"If I run through the number series, I either eventually come to a number with the property ϵ or I never do." The expression "to run through the number series" is nonsense; unless a sense is *given* to it which removes the suggested analogy with "running through the numbers from 1 to 100".

Page 458

When Brouwer attacks the application of the law of excluded middle in mathematics, he is right in so far as he is directing his attack against a process analogous to the proof of empirical propositions. In mathematics you can never prove something like *this*: I saw two apples lying on the table, and now there is only *one* there, so A has eaten an apple. That is, you can't by excluding certain possibilities prove a new one which isn't already contained in the exclusion because of the rules we have laid down. To that extent there are no genuine alternatives in mathematics. If mathematics was the investigation of empirically given aggregates, one could use the exclusion of a part to describe what was not excluded, and in that case the non-excluded part would not be equivalent to the exclusion of the others.

Page 458

The whole approach that if a proposition is valid for one region of mathematics it need not necessarily be valid for a second region as well, is quite out of place in mathematics, completely contrary to its essence. Although many authors hold just this approach to be particularly subtle and to combat prejudice.

Page 458

It is only if you investigate the relevant propositions and their proofs that you can recognize the nature of the generality of the propositions of mathematics that treat not of "all cardinal numbers" but e.g. of "all real numbers".

Page 458

How a proposition is verified is what it says. Compare generality in arithmetic with the generality of non-arithmetical propositions.

Page Break 459

It is differently verified and so is of a different kind. The verification is not a mere token of the truth, but determines the sense of the proposition. (Einstein: how a magnitude is measured is what it is.)

Page Break 460

Page 460

A misleading picture: "The rational points lie close together on the number-line."

Page 460

Is a space thinkable that contains all rational points, but not the irrational ones? Would this structure be too coarse for our space, since it would mean that we could only reach the irrational points approximately? Would it mean that our net was not fine enough? No. What we would lack would be the laws, not the extensions.

Page 460

Is a space thinkable that contains all rational points but not the irrational ones?

Page 460

That only means: don't the rational numbers set a precedent for the irrational numbers?

Page 460

No more than draughts sets a precedent for chess.

There isn't any gap left open by the rational numbers that is filled up by the irrationals.

We are surprised to find that "between the everywhere dense rational points", there is still room for the irrationals. (What balderdash!) What does a construction like that for $\sqrt{2}$ show? Does it show how there is yet room for this point in between all the rational points? It shows that the point *yielded* by the construction, yielded by *this* construction, is *not rational*.--And what corresponds to this construction in arithmetic? A sort of number which manages *after all* to squeeze in between the rational numbers? A law that is not a law of the nature of a rational number.

The explanation of the Dedekind cut pretends to be clear when it says: there are 3 cases: either the class R has a first member and L no last member, etc. In fact two of these 3 cases cannot be imagined, unless the words "class", "first member", "last member", altogether change the everyday meanings they [[sic]] are supposed to have retained.

That is, if someone is dumbfounded by our talk of a class of points that lie to the right of a given point and have no beginning, and says: give us an example of such a class--we trot out the class of rational numbers; but that isn't a class of points in the original sense.

The point of intersection of two curves isn't the common member of two classes of points, it's the meeting of two laws. Unless, very misleadingly, we use the second form of expression to define the first.

After all I have already said, it may sound trivial if I now say that the mistake in the set-theoretical approach consists time and again in treating laws and enumerations (lists) as essentially the same kind of thing and arranging them in parallel series so that one fills in gaps left by another.

The symbol for a class is a list.

Here again, the difficulty arises from the formation of mathematical pseudo-concepts. For instance, when we say that we can arrange the cardinal numbers, but not the rational numbers, in a series according to their size, we are unconsciously presupposing that the concept of an ordering by size does have a sense *for rational numbers*, and that it turned out on investigation that the ordering was impossible (which presupposes that the *attempt* is thinkable).--Thus one thinks that it is possible to attempt to arrange *the real numbers* (as if that were a concept of the same kind as 'apple on this table') in a series, and now it turned out to be impracticable.

For its form of expression the calculus of sets relies as far as possible on the form of expression of the calculus of cardinal numbers. In some ways that is instructive, since it indicates certain formal similarities, but it is also misleading, like calling something a knife that has neither blade nor handle. (Lichtenberg.)

(The only point there can be to elegance in a mathematical proof is to reveal certain analogies in a particularly striking manner, when that is what is wanted; otherwise it is a product of stupidity and its only effect is to obscure what ought to be clear and manifest. The stupid pursuit of elegance is a principal cause of the mathematicians' failure to understand their own operations; or perhaps the lack of understanding and the pursuit of elegance have a common origin.)

Human beings are entangled all unknowing in the net of language.

"There is a point where the two curves intersect." How do you know that? If you tell me, I will know what sort of sense the proposition "there is..." has.

If you want to know what the expression "the maximum of a curve" means, ask yourself: how does one find it?--If something is found in a different way it is a different thing. We define the maximum as the point on the curve higher than all the others, and from that we get the idea that it is only our human weakness that prevents us from

sifting through the points of the curve one by one and selecting the highest of them. And this leads to the idea that the highest point among a finite number of points is essentially the same as the highest point of a curve, and that we are simply finding out the same thing by two different methods, just as we find out in two different ways that there is no one in the next room; one way if the door is shut and we aren't strong enough to open it, and another way if we can get inside. But, as I said, it isn't human weakness that's in question where the alleged description of the action "that we cannot perform" is senseless. Of course it does no harm, indeed it's very interesting, to see the analogy between the maximum of a curve and the maximum (in another sense) of a class of points, provided that the analogy doesn't instil the prejudice that in each case we have fundamentally the same thing.

Page Break 463

Page 463

It's the same defect in our syntax which presents the geometrical proposition "a length may be divided by a point into two parts" as a proposition of the same form as "a length may be divided for ever"; so that it looks as if in both cases we can say "Let's suppose the possible division to have been carried out". "Divisible into two parts" and "infinitely divisible" have quite different grammars. We mistakenly treat the word "infinite" as if it were a number word, because in everyday speech both are given as answers to the question "how many?"

Page 463

"But after all the maximum is higher than any other arbitrary points of the curve." But the curve is not composed of points, it is a law that points obey, or again, a law according to which points can be constructed. If you now ask: "which points?" I can only say, "well, for instance, the points P, Q, R, etc." On the one hand we can't give a number of points and say that they are all the points that lie on the curve, and on the other hand we can't speak of a totality of points as something describable which although we humans cannot count them might be called the totality of all the points of the curve--a totality too big for us human beings. On the one hand there is a law, and on the other points on the curve;--but not "all the points of the curve". The maximum is higher than any point of the curve that happens to be constructed, but it isn't higher than a totality of points, unless the criterion for that, and thus the sense of the assertion, is once again simply construction according to the law of the curve.

Page 463

Of course the web of errors in this region is a very complicated one. There is also e.g. the confusion between two different meanings of the word "kind". We admit, that is, that the infinite numbers are a different *kind* of number from the finite ones, but then we misunderstand what the difference between different kinds amounts to in this case. We don't realise, that is, that it's not a matter of distinguishing between objects by their properties in the way we distinguish between red and yellow apples, but a matter of different logical forms.--Thus Dedekind tried to *describe* an infinite class

Page Break 464

by saying that it is a class which is similar to a proper subclass of itself. Here it looks as if he has given a property that a class must have in order to fall under the concept "infinite class" (Frege).†1 Now let us consider how this definition is applied. I am to investigate in a particular case whether a class is finite or not, whether a certain row of trees, say, is finite or infinite. So, in accordance with the definition, I take a subclass of the row of trees and investigate whether it is similar (i.e. can be co-ordinated one-to-one) to the whole class! (Here already the whole thing has become laughable.) It hasn't any meaning; for, if I take a "finite class" as a sub-class, the attempt to coordinate it one-to-one with the whole class must *eo ipso* fail: and if I make the attempt with an infinite class--but already that is a piece of nonsense, for if it is infinite, I cannot make an attempt to co-ordinate it.--What we call 'correlation of all the members of a class with others' in the case of a finite class is something quite different from what we, e.g., call a correlation of all cardinal numbers with all rational numbers. The two correlations, or what one means by these words in the two cases, belong to different logical types. An infinite class is not a class which contains more members than a finite one, in the ordinary sense of the word "more". If we say that an infinite number is greater than a finite one, that doesn't make the two comparable, because in that statement the word "greater" *hasn't the same meaning* as it has say in the proposition $5 > 4$!

Page 464

That is to say, the definition pretends that whether a class is finite or infinite follows from the success or failure of the attempt to correlate a proper subclass with the whole class; whereas there just isn't any such decision procedure.--'Infinite class' and 'finite class' are different logical categories; what can be significantly

Page Break 465

asserted of the one category cannot be significantly asserted of the other.

With regard to finite classes the proposition that a class is not similar to its sub-classes is not a truth but a tautology. It is the grammatical rules for the generality of the general implication in the proposition "k is a subclass of K" that contain what is said by the proposition that K is an infinite class.

A proposition like "there is no last cardinal number" is offensive to naive--and correct--common sense. If I ask "Who was the last person in the procession?" and am told "There wasn't a last person" I don't know what to think; what does "There wasn't a last person" mean? Of course, if the question had been "Who was the standard bearer?" I would have understood the answer "There wasn't a standard bearer"; and of course the bewildering answer is modelled on an answer of that kind. That is, we feel, correctly, that where we can speak at all of a last one, there can't be "No last one". But of course that means: The proposition "There isn't a last one" should rather be: it makes no sense to speak of a "last cardinal number", that expression is ill-formed.

"Does the procession have an end?" might also mean: is the procession a compact group? And now someone might say: "There, you see, you can easily imagine a case of something not having an end; so why can't there be other such cases?"--But the answer is: The "cases" in this sense of the word are grammatical cases, and it is they that determine the sense of the question. The question "Why can't there be other such cases?" is modelled on: "Why can't there be other minerals that shine in the dark"; but the latter is about cases where a statement is true, the former about cases that determine the sense.

The form of expression " $m = 2n$ correlates a class with one of its proper subclasses" uses a misleading analogy to clothe a trivial sense in a paradoxical form. (And instead of being ashamed of

this paradoxical form as something ridiculous, people plume themselves on a victory over all prejudices of the understanding). It is exactly as if one changed the rules of chess and said it had been shown that chess could also be played quite differently. Thus we first mistake the word "number" for a concept word like "apple", then we talk of a "number of numbers" and we don't see that in this expression we shouldn't use the same word "number" twice; and finally we regard it as a discovery that the number of the even numbers is equal to the number of the odd and even numbers.

It is less misleading to say " $m = 2n$ allows the possibility of correlating every time with another" than to say " $m = 2n$ correlates all numbers with others". But here too the grammar of the meaning of the expression "possibility of correlation" has to be learnt.

(It's almost unbelievable, the way in which a problem gets completely barricaded in by the misleading expressions which generation upon generation throw up for miles around it, so that it becomes virtually impossible to get at it.)

If two arrows point in the same direction, isn't it in such a case absurd to call these directions equally *long*, because whatever lies in the direction of the one arrow, also lies in that of the other?--The generality of $m = 2n$ is an arrow that points along the series generated by the operation. And you can even say that the arrow points to infinity; but does that mean that there is something--infinity--at which it points, as at a thing?--It's as though the arrow designates the possibility of a position in its direction. But the word "possibility" is misleading, since someone will say: let what is possible now become actual. And in thinking this we always think of a temporal process, and infer from the fact that mathematics has nothing to do with time, that in its case possibility is already actuality.

The "infinite series of cardinal numbers" or "the concept of cardinal number" is only such a possibility--as emerges clearly

from the symbol " $|0, \xi, \xi + 1|$ ". This symbol is itself an arrow with the "0" as its tail and the " $\xi + 1$ " as its tip. It is possible to speak of things which lie in the direction of the arrow, but misleading or absurd to speak of all possible positions for things lying in the direction of the arrow as an equivalent for the arrow itself. If a searchlight sends out light into infinite space it illuminates everything in its direction, but you can't say it illuminates infinity.

It is always right to be extremely suspicious when proofs in mathematics are taken with greater generality

than is warranted by the known application of the proof. This is always a case of the mistake that sees general concepts and particular cases in mathematics. In set theory we meet this suspect generality at every step.

Page 467

One always feels like saying "let's get down to brass tacks".

Page 467

These general considerations only make sense when we have a particular region of application in mind.

Page 467

In mathematics there isn't any such thing as a generalization whose application to particular cases is still unforeseeable. That's why the general discussions of set theory (if they aren't viewed as *calculi*) always sound like empty chatter, and why we are always astounded when we are shown an application for them. We feel that what is going on isn't properly connected with real things.

Page 467

The distinction between the general truth that one can know, and the particular that one doesn't know, or between the known description of the object, and the object itself that one hasn't seen, is another example of something that has been taken over into logic from the physical description of the world. And that too is where we get the idea that our reason can recognize questions but not their answers.

Page Break 468

Page 468

Set theory attempts to grasp the infinite at a more general level than the investigation of the laws of the real numbers. It says that you can't grasp the actual infinite by means of mathematical symbolism at all and therefore it can only be described and not represented. The description would encompass it in something like the way in which you carry a number of things that you can't hold in your hand by packing them in a box. They are then invisible but we still know we are carrying them (so to speak, indirectly). One might say of this theory that it buys a pig in a poke. Let the infinite accommodate itself in this box as best it can.

Page 468

With this there goes too the idea that we can use language to *describe* logical forms. In a description of this sort the structures are presented in a package and so it does look as if one could speak of a structure without reproducing it in the proposition itself. Concepts which are packed up like this may, to be sure, be used, but our signs derive their meaning from definitions which package the concepts in this way; and if we follow up these definitions, the structures are uncovered again. (Cf. Russell's definition of "R*".)

Page 468

When "all apples" are spoken of, it isn't, so to speak, any concern of logic how many apples there are. With numbers it is different; logic is responsible for each and every one of them.

Page 468

Mathematics consists entirely of calculations.

Page 468

In mathematics *everything* is algorithm and *nothing* is meaning; even when it doesn't look like that because we seem to be using *words* to talk *about* mathematical things. Even these words are used to construct an algorithm.

Page 468

In set theory what is calculus must be separated off from what attempts to be (and of course cannot be) *theory*. The rules of the game have to be separated off from inessential statements about the chessmen.

Page 468

In Cantor's alleged definition of "greater", "smaller", "+", "-"

Page Break 469

Page 469

Frege replaced the signs with new words to show the definition wasn't really a definition.†1 Similarly in the whole of mathematics one might replace the usual words, especially the word "infinite" and its cognates, with entirely new and hitherto meaningless expressions so as to see what the calculus with these signs really achieves and what it fails to achieve. If the idea was widespread that chess gave us information about kings and castles, I would propose to give the pieces new shapes and different names, so as to demonstrate that everything belonging to chess has to be contained in the rules.

Page 469

What a geometrical proposition means, what kind of generality it has, is something that must show itself when we see how it is applied. For even if someone succeeded in meaning something intangible by it it wouldn't help him, because he can only apply it in a way which is quite open and intelligible to every one.

Similarly, if someone imagined the chess king as something mystical it wouldn't worry us since he can only move him on the 8×8 squares of the chess board.

We have a feeling "There can't be possibility and actuality in mathematics. It's all on *one* level. And is in a certain sense, *actual*.--And that is correct. For mathematics is a calculus; and the calculus does not say of any sign that it is merely *possible*, but is concerned only with the signs with which it *actually* operates. (Compare the foundations of set theory with the assumption of a possible calculus with infinite signs).

When set theory appeals to the human impossibility of a direct symbolisation of the infinite it brings in the crudest imaginable misinterpretation of its own calculus. It is of course this very misinterpretation that is responsible for the invention of the calculus. But of course that doesn't show the calculus in itself to

be something incorrect (it would be at worst uninteresting) and it is odd to believe that this part of mathematics is imperilled by any kind of philosophical (or mathematical) investigations. (As well say that chess might be imperilled by the discovery that wars between two armies do not follow the same course as battles on the chessboard.) What set theory has to lose is rather the atmosphere of clouds of thought surrounding the bare calculus, the suggestion of an underlying imaginary symbolism, a symbolism which isn't employed in its calculus, the apparent description of which is really nonsense. (In mathematics anything can be imagined, except for a part of our calculus.)

The extensional conception of the real numbers

Like the enigma of time for Augustine, the enigma of the continuum arises because language misleads us into applying to it a picture that doesn't fit. Set theory preserves the inappropriate picture of something discontinuous, but makes statements about it that contradict the picture, under the impression that it is breaking with prejudices; whereas what should really have been done is to point out that the picture just doesn't fit, that it certainly can't be stretched without being torn, and that instead of it one can use a new picture in certain respects similar to the old one.

The confusion in the concept of the "actual infinite" arises from the unclear concept of irrational number, that is, from the fact that logically very different things are called "irrational numbers" without any clear limits being given to the concept. The illusion that we have a firm concept rests on our belief that in signs of the the [sic] form "o.abcd... ad infinitum" we have a pattern to which they (the irrational numbers) have to conform whatever happens.

"Suppose I cut a length at a place where there is no rational point (no rational number)." But can you do that? What sort of a length are you speaking of? "But if my measuring instruments were fine enough, at least I could approximate without limit to a certain point by continued bisection"!--No, for I could never tell whether my point was a point of this kind. All I could tell would always be that I hadn't reached it. "But if I carry out the construction of $\sqrt{2}$ with absolutely exact drawing instruments, and then by bisection approximate to the point I get, I *know* that this process will never reach the constructed point." But it would be odd if one construction could as it were prescribe something to the others in this way! And indeed that isn't the way it is. It is very possible that

the point I get by means of the 'exact' construction of $\sqrt{2}$ is reached by the bisection after say 100 steps;--but in that case we could say: our space is not Euclidean.

The "cut at the irrational point" is a picture, and a misleading picture.

A cut is a *principle* of division into greater and smaller.

Does a cut through a length determine in advance the results of all bisections meant to approach the point of the cut? No.

In the previous example†1 in which I threw dice to guide me in the successive reduction of an interval by the bisection of a length I might just as well have thrown dice to guide me in the writing of a decimal. Thus the description "endless process of choosing between 1 and 0" does not determine a law in the writing of a decimal. Perhaps you feel like saying: the prescription for the endless choice between 0 and 1 in this case could be

reproduced by a symbol like " $0.\overset{000}{111} \dots \text{ad. inf.}$ ". But if I adumbrate a law thus ' $0.001001001 \dots \text{ad. inf.}$ ', what I want to show is not the finite section of the series as a specimen of the infinite series, but rather the kind of regularity to be perceived in it. But in " $0.\overset{000}{111} \dots \text{ad. inf.}$ " I don't perceive *any* law,--on the contrary, precisely that a law is absent.

Page 472

(What criterion is there for the irrational numbers being complete? Let us look at an irrational number: it runs through a series of rational approximations. When does it leave this series behind? Never. But then, the series also never comes to an end.

Page 472

Suppose we had the totality of all irrational numbers with one single exception. How would we feel the lack of this one? And--if

Page Break 473

it were to be added--how would it fill the gap? Suppose that it's π . If an irrational number is given through the totality of its approximations, then up to *any* point taken at random there is a series coinciding with that of π . Admittedly for each such series there is a point where they diverge. But this point can lie arbitrarily far 'out', so that for any series agreeing with π I can find one agreeing with it still further. And so if I have the totality of all irrational numbers except π , and now insert π I cannot cite a point at which π is now really needed. At *every* point it has a companion agreeing with it from the beginning on.

Page 473

To the question "how would we feel the lack of π " our answer must be "if π were an extension, we would never feel the lack of it". i.e. it would be impossible for us to observe a gap that it filled. But if someone asked us 'But have you then an infinite decimal expansion with the figure m in the r-th place and n in the s-th place, etc?' we could always oblige him.)

Page 473

"The decimal fractions developed in accordance with a law still need supplementing by an infinite set of irregular infinite decimal fractions that would be 'brushed under the carpet' if we were to *restrict* ourselves to those *generated by a law*." Where is there such an infinite decimal that is generated by no law? And how would we notice that it was missing? Where is the gap it is needed to fill?

Page 473

What is it like if someone so to speak checks the various laws for the construction of binary fractions by means of the set of finite combinations of the numerals 0 and 1?--The results of a law run through the finite combinations and hence the laws are complete as far as their extensions are concerned, once *all* the finite combinations have been gone through.

Page 473

If one says: two laws are identical in the case where they yield the same result at every stage, this looks like a quite general rule. But in reality the proposition has different senses depending on

Page Break 474

what is the criterion for their yielding the same result at every stage. (For of course there's no such thing as the supposed generally applicable method of infinite checking!) Thus under a mode of speaking derived from an analogy we conceal the most various meanings, and then believe that we have united the most various cases into a single system.

Page 474

(The laws corresponding to the irrational numbers all belong to the same type to the extent that they must all ultimately be recipes for the successive construction of decimal fractions. In a certain sense the common decimal notation gives rise to a common type.)

Page 474

We could also put it thus: *every* point in a length can be approximated to by *rational* numbers by repeated bisection. There is no point that can only be approximated to by irrational steps of a specified type. Of course, that is

only a way of clothing in different words the explanation that by irrational numbers we mean endless decimal fractions; and that explanation in turn is only a rough explanation of the decimal notation, plus perhaps an indication that we distinguish between laws that yield recurring decimals and laws that don't.

Page 474

The incorrect idea of the word "infinite" and of the role of "infinite expansion" in the arithmetic of the real numbers gives us the false notion that there is a uniform notation for irrational numbers (the notation of the infinite extension, e.g. of infinite decimal fractions).

Page 474

The proof that for every pair of cardinal numbers x and y $(x/y)^2 \neq 2$ does not correlate $\sqrt{2}$ with a *single* type of number--called "the irrational numbers". It is not as if this type of number was constructed before I construct it; in other words, I don't know any more about this new type of number than I tell myself.

Page Break 475

Kinds of irrational numbers

Page 475

π' is a rule for the formation of decimal fractions: the expansion of π' is the same as the expansion of π except where the sequence 777 occurs in the expansion of π ; in that case instead of the sequence 777 there occurs the sequence 000. There is no method known to our calculus of discovering where we encounter such a sequence in the expansion of π .

Page 475

P is a rule for the construction of binary fractions. At the n th place of the expansion there occurs a 1 or a 0 according to whether n is prime or not.

Page 475

F is a rule for the construction of binary fractions. At the n th place there is a 0 unless a triple x, y, z from the first 100 cardinal numbers satisfies the equation $x^n + y^n = z^n$.

Page 475

I'm tempted to say, the individual digits of the expansion (of π for example) are always only the results, the bark of the fully grown tree. What counts, or what something new can still grow from, is the inside of the trunk, where the tree's vital energy is. Altering the surface doesn't change the tree at all. To change it, you have to penetrate the trunk which is still living.

Page 475

I call " π_n " the expansion of π up to the n th place. Then I can say: I understand what π'_{100} means, but not what π' means, since π has no places, and I can't substitute others for none. It would be different if I e.g. defined the

division $\overset{5 \rightarrow 3}{a/b}$ as a rule for the formation of decimals by division and the replacements of every 5 in the quotient

by a 3. In this case I am acquainted, for instance, with the number $\overset{5 \rightarrow 3}{1/7}$. --And if our calculus contains a method, a law, to calculate the position of 777 in the expansion of π , then the law of π includes a mention of 777 and the law can be altered by the substitution of 000 for 777. But in that case π' isn't the same as what

Page Break 476

I defined above; it has a different grammar from the one I supposed. In our calculus there is no question whether π is π' or not, no such equation or inequality. π' is not comparable with π . And one can't say "not *yet* comparable", because if at some time I construct something similar to π' that is comparable to π , then for that very reason it will no longer be π' . For π' like π is a way of denoting a game, and I cannot say that draughts is not *yet* played with as many pieces as chess, on the grounds that it might develop into a game with 16 pieces. In that case it will no longer be what we call "draughts" (unless by this word I mean not a game, but a characteristic of several games or something similar; and this rider can be applied to π and π' too). But since being comparable with other numbers is a fundamental characteristic of a number, the question arises whether one is to call π' a number, and a real number; but whatever it is *called* the essential thing is that π' is not a number in the same sense as π . I can also call an interval a point and on occasion it may even be practical to do so; but does it become more like a point if I forget that I have used the word "point" with two different meanings?

Here it is clear that the possibility of the decimal expansion does not make π' a number in the same sense as π . Of course the rule for this expansion is unambiguous, as unambiguous as that for π or $\sqrt{2}$; but that is no proof that π' is a real number, if one takes comparability with rational numbers as an essential mark of real numbers. One can indeed abstract from the distinction between the rational and irrational numbers, but that does not make the distinction disappear. Of course, the fact that π' is an unambiguous rule for decimal fractions naturally signifies a similarity between π' and π or $\sqrt{2}$; but equally an interval has a similarity with a point etc. All the errors that have been made in this chapter of the philosophy of mathematics are based on the confusion between internal properties of a form (a rule as one among a list of rules) and what we call "properties" in everyday life (red as a property

of this book). We might also say: the contradictions and unclarities are brought about by people using a single word, e.g. "number", to mean at one time a definite set of rules, and at another time a variable set, like meaning by "chess" on one occasion the definite game we play today, and on another occasion the substratum of a particular historical development.

"How far must I expand π in order to have some acquaintance with it?"--Of course that is nonsense. We are already acquainted with it without expanding it at all. And in the same sense I might say that I am not acquainted with π' at all. Here it is quite clear that π' belongs to a different system from π ; that is something we recognize if we keep our eyes on the nature of the laws instead of comparing "the expansions" of both.

Two mathematical forms, of which one but not the other can be compared in my calculus with every rational number, are not numbers in the same sense of the word. The comparison of a number to a point on the number-line is valid only if we can say for every two numbers a and b whether a is to the right of b or b to the right of a.

It is not enough that someone should--supposedly--determine a point ever more closely by narrowing down its whereabouts. We must be able to construct *it*. To be sure, continued throwing of a die indefinitely restricts the possible whereabouts of a point, but it doesn't determine a point. After *every* throw (or every choice) the point is still infinitely indeterminate--or, more correctly, after every throw it is infinitely indeterminate. I think that we are here misled by the *absolute* size of the objects in our visual field; and on the other hand, by the ambiguity of the expression "to approach a point". We can say of a line in the visual field that by shrinking it is approximating more and more to a point--that is, it is becoming more and more similar to a point. On the other hand when a Euclidean line shrinks it does *not* become any more like a point; it always remains totally dissimilar, since its length, so to say,

never gets anywhere near a point. If we say of a Euclidean line that it is approximating to a point by shrinking, that only makes sense if there is an already designated point which its ends are approaching; it cannot mean that by shrinking it *produces* a point. To approach a point has two meanings: in one case it means to come spatially nearer to it, and in that case the point must already be there, because in this sense I cannot approach a man who doesn't exist; in the other case, it means "to become more like a point", as we say for instance that the apes as they developed approached the stage of being human, their development produced human beings.

To say "two real numbers are identical if their expansions coincide in *all* places" only has sense in the case in which, by producing a method of establishing the coincidence, I have *given* a sense to the expression "to coincide in all places". And the same naturally holds for the proposition "they do not coincide if they disagree in *any one* place".

But conversely couldn't one treat π' as the original, and therefore as the first assumed point, and then be in doubt about the justification of π ? As far as concerns their extension, they are naturally on the same level; but what causes us to call π a point on the number-line is its comparability with the rational numbers.

If I view π , or let's say $\sqrt{2}$, as a rule for the construction of decimals, I can naturally produce a modification of this rule by saying that every 7 in the development of $\sqrt{2}$ is to be replaced by a 5; but this modification is of quite a different *nature* from one which is produced by an alteration of the radicant or the exponent of the radical sign or the like. For instance, in the modified law I am including a reference to the number system of the expansion which wasn't in the original rule for $\sqrt{2}$. The alternation of the law is of a much more fundamental kind than might

at first appear.

Page Break 479

Of course, if we have the incorrect picture of the infinite extension before our minds, it can appear as if appending the substitution rule $7 \rightarrow 5$ to $\sqrt{2}$ alters it much less than altering $\sqrt{2}$ into $\sqrt{2 \cdot 1}$, because the expansions of $\sqrt{2}$ are very similar to those of $\sqrt{2}$, whereas the expansion of $\sqrt{2 \cdot 1}$ deviates from that of $\sqrt{2}$ from the second place onwards.

Page 479

Suppose I give a rule ρ for the formation of extensions in such a way that my calculus knows no way of predicting what is the maximum number of times an apparently recurring stretch of the extension can be repeated. That differs from a real number because in certain cases I can't compare $\rho - a$ with a rational number, so that the expression $\rho - a = b$ becomes nonsensical. If for instance the expansion of ρ so far known to me is $3 \cdot 14$ followed by an open series of ones ($3 \cdot 141111\dots$), it wouldn't be possible to say of the difference $\rho - 3 \cdot 14\bar{1}$ whether it was greater or less than 0; so in this sense it can't be compared with 0 or with a point on the number axis and it and ρ can't be called number in the same sense as one of these points.

Page 479

[The extension of a concept of number, or of the concept 'all', etc. seems quite harmless to us; but it stops being harmless as soon as we forget that we have in fact changed our concept.]

Page 479

[So far as concerns the irrational numbers, my investigation says only that it is incorrect (or misleading) to speak of irrational numbers in such a way as to contrast them with cardinal numbers and rational numbers as a different kind of number; because what are called "irrational numbers" are species of number that are really different--as different from each other as the rational numbers are different from each of them.]

Page 479

"Can God know all the places of the expansion of π ?" would have been a good question for the schoolmen to ask.

Page Break 480

Page 480

In these discussions we are always meeting something that could be called an "arithmetical experiment". Admittedly the data determine the result, but I can't see *in what way* they determine it. That is how it is with the occurrences of the 7s in the expansion of π ; the primes likewise are yielded as the result of an experiment. I can ascertain that 31 is a prime number, but I do not see the connection between it (its position in the series of cardinal numbers) and the condition it satisfies.--But this perplexity is only the consequence of an incorrect expression. The connection that I think I do not see does not exist. There is not an--as it were irregular--occurrence of 7s in the expansion of π , because there isn't any series that is called *the* expansion of π . There are expansions of π , namely those that have been worked out (perhaps 1000) and in those the 7s don't occur "irregularly" because their occurrence can be described. (The same goes for the "distribution of the primes". If you give as a law for this distribution, you give us a *new* number series, *new* numbers.) (A law of the calculus that I do not know is not a law.) (Only what I *see* is a law; not what I *describe*. That is the only thing standing in the way of my expressing more in my signs that I can understand.)

Page 480

Does it make no sense to say, even after Fermat's last theorem has been proved, that $F = 0 \cdot 11$? (If, say I were to read about it in the papers.) I will indeed then say, "so now we can write ' $F = 0 \cdot 11$ '." That is, it is tempting to adopt the sign "F" from the earlier calculus, in which it didn't denote a rational number, into the new one and now to denote $0 \cdot 11$ with it.

Page 480

F was supposed to be a number of which we did not know whether it was rational or irrational. Imagine a number, of which we do not know whether it is a cardinal number or a rational number. A description in the calculus is worth just as much as this particular set of words and it has nothing to do with an object given by description which may someday be found.

Page Break 481

Page 481

What I mean could also be expressed in the words: one cannot discover any connection between parts of mathematics or logic that was already there without one knowing.

Page 481

In mathematics there is no "not yet" and no "until further notice" (except in the sense in which we can say that we haven't yet multiplied two 1000 digit numbers together.)

Page 481

"Does the operation yield a rational number for instance?"--How can that be asked, if we have no method for deciding the question? For it is only in an established calculus that the operation *yields* results. I mean: "yields" is essentially timeless. It doesn't mean "yields, given time"--but: yields in accordance to the rules already known and established.

Page 481

"The position of all primes must somehow be predetermined. We work them out only successively, but they are all already determined. God, as it were, knows them all. And yet for all that it seems possible that they are not determined by a law."--Always this picture of the meaning of a word as a full box which is given us with its contents packed in it all ready for us to investigate.--What *do* we know about the prime numbers? How is the concept of them given to us at all? Don't we ourselves make the decisions about them? And how odd that we assume that there must have been decisions taken about them that we haven't taken ourselves! But the mistake is understandable. For we use the expression "prime number" and it sounds similar to "cardinal number", "square number", "even number" etc. So we think it will be used in the same way, and we forget that for the expression "prime number" we have given quite different rules--rules *different in kind*--and we find ourselves at odds with ourselves in a strange way.--But how is that possible? After all the prime numbers are familiar cardinal numbers--how can one say that the concept of prime number is not a number concept in the same sense as the concept of cardinal number? But here again we are tricked by the image of an "infinite extension" as an analogue to the familiar "finite "extension. Of course the concept 'prime number'

Page Break 482

is defined by means of the concept 'cardinal number', but "the prime numbers" aren't defined by means of "the cardinal numbers", and the way *we* derived the concept 'prime number' from the concept 'cardinal number' is essentially different from that in which we derived, say, the concept 'square number'. (So we cannot be surprised if it behaves differently.) One might well imagine an arithmetic which--as it were--didn't stop at the concept 'cardinal number' but went straight on to that of square numbers. (Of course that arithmetic couldn't be applied in the same way as ours.) But then the concept "square number" wouldn't have the characteristic it has in our arithmetic of being essentially a part-concept, with the square numbers essentially a sub-class of the cardinal numbers; in that case the square numbers would be a complete series with a complete arithmetic. And now imagine the same done with the prime numbers! That will make it clear that they are not "numbers" in the same sense as e.g. the square numbers or the cardinal numbers.

Page 482

Could the calculations of an engineer yield the result that the strength of a machine part in proportion to regularly increasing loads must increase in accordance with the series of primes?

Page Break 483

43

Irregular infinite decimals

Page 483

"Irregular infinite decimals". We always have the idea that we only have to bring together the words of our everyday language to give the combinations a sense, and all we then have to do is to inquire into it--supposing it's not quite clear right away. It is as if words were ingredients of a chemical compound, and we shook them together to make them combine with each other, and then had to investigate the properties of the compound, If someone said he didn't understand the expression "irregular infinite decimals" he would be told "that's not true, you understand it very well: don't you know what the words "irregular", "infinite", and "decimal" mean?--well, then, you understand their combination as well." And what is meant by "understanding" here is that he knows how to apply these words in certain cases, and say *connects an image with them*. In fact, someone who puts these words together and asks "what does it mean" is behaving rather like small children who cover a paper with random scribbles, show it to grown-ups, and ask "what is that?"

Page 483

"Infinitely complicated law", "infinitely complicated construction" ("Human beings believe, if only they hear words, there must be something that can be thought with them").

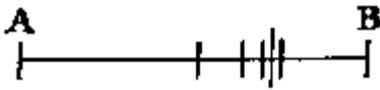

How does an infinitely complicated law differ from the lack of any law?

(Let us not forget: mathematicians' discussions of the infinite are clearly finite discussions. By which I mean, they come to an end.)

"One can imagine an irregular infinite decimal being constructed by endless dicing, with the number of pips in each case being a decimal place." But, if the dicing goes on for ever, no final result ever comes out.

"It is only the human intellect that is incapable of grasping it, a higher intellect could do so!" Fine, then describe to me the grammar of the expression "higher intellect"; what can such an intellect grasp and what can't it grasp and in what cases (in experience) do I say that an intellect grasps something? You will then see that describing grasping is itself grasping. (Compare: the solution of a mathematical problem.)

Suppose we throw a coin heads and tails and divide an interval AB in accordance with the following rule: "Heads" means: take the left half and divide it in the way the next throw prescribes. "Tails" says "take the right half, etc." By repeated throws I then

get dividing-points that move in an ever smaller interval. Does it amount to a description of the position of a point if I say that it is the one infinitely approached by the cuts as prescribed by the repeated tossing of the coin? Here one believes oneself to have determined a point corresponding to an irregular infinite decimal. But the description doesn't determine *any* point *explicitly*; unless one says that the words "point on this line" also "determine a point"! Here we are confusing the recipe for throwing with a mathematical rule like that for producing decimal places of $\sqrt{2}$. Those mathematical rules *are* the points. That is, you can find relations between those rules that resemble in their grammar the relations "larger" and "smaller" between two lengths, and that is why they are referred to by these words. The rule for working out places of $\sqrt{2}$ is itself the numeral for the irrational number; and the reason I here speak of a "number" is that I can calculate with these signs (certain rules for the construction of rational numbers) just as I can with rational numbers themselves. If I want to say similarly

that the recipe for endless bisection according to heads and tails determines a point, that would have to mean that this recipe could be used as a numeral, i.e. in the same way as other numerals. But of course that is not the case. If the recipe were to correspond to a numeral at all, it would at best correspond to the indeterminate numeral "some", for all it does is to leave a number open. In a word, it corresponds to nothing except the original interval.

Note in Editing

In June 1931 Wittgenstein wrote a parenthesis in his manuscript book: "(My book might be called: Philosophical Grammar. This title would no doubt have the smell of a textbook title but that doesn't matter, for behind it there is the book.)" In the next four manuscript volumes after this he wrote nearly everything that is in the present work. The second of these he called "Remarks towards Philosophical Grammar" and the last two "Philosophical Grammar".

The most important source for our text is a large typescript completed probably in 1933, perhaps some of it 1932. Our "Part II" makes up roughly the second half of this typescript. In most of the first half of it Wittgenstein made repeated changes and revisions--between the lines and on the reverse sides of the typed sheets--and probably in the summer of 1933 he began a "Revision" in a manuscript volume (X and going over into XI). This, with the "Second Revision" (which I will explain), is the text of our Part I up to the Appendix.--Wittgenstein simply wrote "*Umarbeitung*" (Revision) as a heading, without a date; but he clearly wrote it in 1933 and the early weeks of 1934.

He did not write the "second revision" in the manuscript volume but on large folio sheets. He crossed out the text that this was to replace, and showed in margins which parts went where. But it is a revision of only a *part*, towards the beginning, of the first and principal "Revision". The passages from the second revision are, in our text, §§1-13 and §§ 23-43. The second revision is not dated either, but obviously it is later than the passages it replaces; probably not later than 1934.

Page 487

So we may take it that he wrote part of this work somewhat earlier, and part at the same time as his dictation of *The Blue Book*. Many things in the *Blue Book* are here (and they are better expressed). There are passages also which are in the *Philosophical Remarks* and others later included in the *Investigations*. It would be easy to give the reference and page number for each of these. We decided not to. This book should be compared with Wittgenstein's earlier and later writings. But this means: the method and the development

Page Break 488

of his discussion here should be compared with the *Philosophical Remarks* and again with the *Investigations*. The footnotes would be a hindrance and, as often as not, misleading. When Wittgenstein writes a paragraph here that is also in the *Remarks*, this does not mean that he is just repeating what he said there. The paragraph may have a different importance, it may belong to the discussion in a different way. (We know there is more to be said on this question.)

Page 488

Wittgenstein refers to "my book" at various times in his manuscripts from the start of 1929 until the latest passages of the *Investigations*. It is what his writing was to produce. The first attempt to form the material into a book was the typescript volume he made in the summer of 1930--the *Philosophical Remarks* (published in German in 1964). The large typescript of 1933--the one we mentioned as a source of this volume--looks like a book. Everyone who sees it first thinks it is. But it is unfinished; in a great many ways. And Wittgenstein evidently looked on it as one stage in the ordering of his material. (Cf. the simile of arranging books on the shelves of a library, in *Blue Book* p. 44-45.)

Page 488

Most of the passages which make up the text of the 1933 typescript (called "213" in the catalogue) he had written in manuscript volumes between July 1930 and July 1932; but not in the order they have in the typescript. From the manuscript volumes he dictated two typescripts, one fairly short and the other much longer--about 850 pages together. There was already a typescript made from manuscripts written *before* July 1930--not the typescript which *was* the *Philosophical Remarks* but a typescript which he cut into parts and sifted and put together in a different way to *make* the *Philosophical Remarks*. He now used an intact copy of this typescript together with the two later ones in the same way, cutting them into strips: small strips sometimes with just one paragraph or one sentence, sometimes groups of paragraphs; and arranging them in the order he saw they ought to have. Groups of slips in their order were clipped together to form 'chapters', and he gave each chapter a title. He then brought the chapters together--in a definite order--to form 'sections'. He gave each section a title and arranged them also in a definite order. In this order the whole was finally typed.--Later he made a table of contents out of the titles of sections and chapter headings.

Page Break 489

Page 489

Certain chapters, especially, leave one feeling that he cannot have thought the typing of the consecutive copy had finished the work barring clerical details. He now wrote, over and over again, between the lines of typescript or in the margin: "Does not belong here", "Belongs on page... above", "Belongs to 'Meaning', § 9", "Goes with 'What is an empirical proposition?'" "Belongs with § 14, p. 58 or § 89 p. 414", and so on. But more than this, about 350 pages--most of the first half of the typescript--are so written over with changes, additions, cancellations, questions and new versions, that no one could ever find the 'correct' text here and copy it--saving the author himself should write it over to include newer versions and make everything shorter.

Page 489

He now makes no division into chapters and sections. He has left out paragraph numbers and any suggestion of a table of contents. We do not know why. (We do not find chapters or tables of contents anywhere else in Wittgenstein's writings. He may have found disadvantages in the experiment he tried here.)--The extra spaces between paragraphs and groups of paragraphs are his own; and he thought these important. He would have numbered paragraphs, probably, as he did in the *Investigations*. But the numbers in Part I here are the editor's, not Wittgenstein's. Neither is the division in chapters Wittgenstein's, nor the table of contents.--On the other hand, Part II has kept the chapters and the table of contents which Wittgenstein gave this part of the typescript. Perhaps this

makes it look as though Part I and Part II were not one work. But we could not make them uniform in this (division and arrangement of chapters) without moving away from Wittgenstein's way of presenting what he wrote. Anyone who reads both parts will see connections.

Page 489

And the appendix may make it plainer. Appendices 5, 6, 7, 8 and the first half of 4 are chapters of 'typescript 213'. Appendix I, *Fact and Complex*, is also an appendix in *Philosophical Remarks*. But Wittgenstein had fastened it together with appendices 2 and 3 and given them a consecutive paging as one essay; with what intention we do not know. Each one of the eight appendices here discusses something connected with 'proposition' and with 'sense of a proposition'. The whole standpoint is somewhat earlier (the manuscripts often bear earlier dates) than that of

Page Break 490

Part I here, but later than the *Philosophical Remarks*.--But the appendices also discuss questions directly connected with the themes of 'generality' and 'logical inference' in Part II.

Page 490

Part I is concerned with the generality of certain expressions or concepts, such as 'language', 'proposition' and 'number'. For instance, § 70, page 113:

Page 490

"Compare the concept of proposition with the concept 'number' and then on the other hand with the concept of cardinal number. We count as numbers cardinal numbers, rational numbers, irrational numbers, complex numbers; whether we call other constructions numbers because of their similarities with these, or draw a definitive boundary here or elsewhere, depends on us. In this respect the concept of number is like the concept of proposition. On the other hand the concept of cardinal number $|1, \xi, \xi + 1|$ can be called a rigorously circumscribed concept, that's to say it's a concept in a different sense of the word."

Page 490

This discussion is closely related to the chapter on '*Kinds of Cardinal Numbers*' and on ' $2 + 2 = 4$ ' in Part II; and with the section on *Inductive Proof*. These are the most important things in Part II.

London, 1969

Page Break 491

Translator's Note

Page 491

Many passages in the *Philosophical Grammar* appear also in the *Philosophical Remarks*, the *Philosophical Investigations*, and the *Zettel*. In these cases I have used the translations of Mr Roger White and Professor G. E. M. Anscombe, so that variations between the styles of translators should not be mistaken for changes of mind on Wittgenstein's part. Rare departures from this practice are marked in footnotes. Passages from the *Philosophical Grammar* appear also in *The Principles of Linguistic Philosophy* of F. Waismann (Macmillan 1965): in these cases I have not felt obliged to follow the English text verbatim, but I am indebted to Waismann's translator.

Page 491

Three words or groups of words constantly presented difficulties in translation.

Page 491

The German word "*Satz*" may be translated "proposition" or "sentence" or (in mathematical and logical contexts) "theorem". I have tried to follow what appears to have been Wittgenstein's own practice when writing English, by using the word "proposition" when the syntactical or semantic properties of sentences were in question, and the word "sentence" when it was a matter of the physical properties of sounds or marks. But it would be idle to pretend that this rule provides a clear decision in every case, and sometimes I have been obliged to draw attention in footnotes to problems presented by the German word.

Page 491

From the *Tractatus* onward Wittgenstein frequently compared a proposition to a *Maßstab*. The German word means a rule or measuring rod: when Wittgenstein used it is clear that he had in mind a rigid object with calibrations. Finding the word "rule" too ambiguous, and the word "measuring-rod" too cumbersome, I have followed the translators of the *Tractatus* in using the less accurate but more natural word "ruler".

Page 491

Translators of Wittgenstein have been criticised for failing to adopt a uniform translation of the word "*übersehen*" and its derivatives, given the importance of the notion of "*übersichtliche Darstellung*" in Wittgenstein's later conception of philosophy. I have

Page Break 492

been unable to find a natural word to meet the requirement of uniformity, and have translated the word and its cognates as seemed natural in each context.

Page 492

Like other translators of Wittgenstein I have been forced to retain a rather Germanic style of punctuation to avoid departing too far from the original. For instance, Wittgenstein often introduced *oratio recta* by a colon instead of by inverted commas. This is not natural in English, but to change to inverted commas would involve making a decision--often a disputable one--about where the quotation is intended to end.

Page 492

I have translated the text of the Suhrkamp-Blackwell edition of 1969 as it stands, with the exception of the passages listed below in which I took the opportunity to correct in translation errors of transcription or printing which had crept into the German text. The pagination of the translation, so far as practicable, matches that of the original edition.

Page 492

I am greatly indebted to Professor Ernst Tugendhat, who assisted me in the first draft of my translation; and to Mr John Thomas, Dr Peter Hacker, Mr Brian McGuinness, Professor G. E. M. Anscombe, Professor Norman Malcolm, Professor G. H. von Wright, Mr Roger White, Dr Anselm Müller, Mr and Mrs J. Tiles and Mr R. Heinaman who assisted me on particular points. My greatest debt is to Mr Rush Rhees, who went very carefully through large sections of a draft version and saved me from many errors while improving the translation in many ways. The responsibility for remaining errors is entirely mine.

Page 492

I am grateful to the British Academy for a Visiting Fellowship which supported me while writing the first draft translation.

- †1. Cf. Tractatus 2. 1513 (Editor).
Page 246
- †1. Cf. Tractatus 5. 132 (Ed.).
Page 288
- †1. Perhaps Wittgenstein inadvertently omitted a negation sign before the second quantifier. (Trs.)
Page 296
- †1. According to Dr. C. Lewy Wittgenstein wrote in the margin of F. P. Ramsey's copy of the *Tractatus* at 6.02: "Number is *the* fundamental idea of calculus and must be introduced as such." This was, Lewy thinks, in the year 1923. See *Mind*, July 1967, p. 422.
Page 308
- †1. *Philosophical Remarks*, p. 119.
Page 315
- †1. F. P. Ramsey, *The Foundations of Mathematics*, London 1931, p. 53.
Page 319
- †1. The section does not mention arithmetic. It may be conjectured that it was never completed. (Ed.)
Page 325
- †1. This is an allusion to the German academic custom of announcing a lecture for, say, 11.15 by scheduling it "11.00 c.t." (Trs.)
Page 339
- †1. For the explanation of this notation, see below, p. 343 f.
Page 340

†1. In the manuscript this paragraph is preceded by the remark: I can work out $17 + 28$ according to the rules, I don't need to give $17 + 28 = 45$ (α) as a rule. So if in a proof there occurs the step from $f(17 + 28)$ to $f(45)$ I don't need to say it took place according to (α); I can cite other rules of the addition table.

Page 340

But what is this like in the $((1) + 1) + 1$ notation? Can I say I could work out e.g. $2 + 3$ in it? And according to which rules? It would go like this:

Page 340

$$\{(1) + 1\} + \{((1) + 1) + 1\} = \{((1) + 1) + 1\} = \{(((1) + 1) + 1) + 1\} \dots \sigma$$

Page 347

†1. Thus according to the typescript. The manuscript reads " $(\exists 3x).\phi x.(\exists 2x).\psi x.$ Ind.: $\supset.(\exists 5x).\phi x \vee \psi x$ ".

Page 364

†1. This paragraph is crossed out in the typescript.

Page 380

†1. Perhaps the problem is to find the number of ways in which we can trace the joins in this wall without interruption, omission or repetition. Cf. *Remarks on the Foundations of Mathematics* p. 174.

Page 383

†1. Here and at one point further down, I have corrected a confusion in Wittgenstein's typescript between "left" and "right" (Tr.).

Page 389

†1. p. 321.

Page 397

†1. *Begründung der Elementaren Arithmetik* von Th. Skolem, Skrifter utg. av. Vid.-Selsk i Kristiana 1923. I Mat.-nat. K. No. 6. p. 5. Translated in van Heijenoort, *From Frege to Gödel*, Harvard University Press, 1967, pp. 302-333.

Page 398

†1. The dash underneath emphasizes that the remainder is equal to the dividend. So the expression becomes the symbol for periodic division. (Ed.)

Page 401

†1. $? (x).\phi x$. (Ed.)

Page 406

†1. Above, p. 397.

Page 408

†1. See the appendix on p. 446. Cf. also *Philosophical Remarks*, p. 194 n.

Page 411

†1. "The schema ρ "--or: the group of equations α , β and γ on p. 397. A little further on Wittgenstein refers to the same group as "R", p. 414 below. Later on p. 433, he speaks again of "the rule R" as here on p. 408, where it is: $a + (b + 1) = (a + b) + 1$. (Ed.)

Page 411

†2. This, probably, refers to those equations on p. 408 to the right of the brackets, that is: $a + (b + c) = (a + b) + c$, $a + 1 = 1 + a$, $a + b = b + a$. $B_I, B_{II}, B_{III} \dots$ will then be the complexes of equations left of the brackets. On the meaning of the brackets, see below (Ed.)

Page 416

†1. "V" denotes a definition which will be given below, p. 441. In the manuscript that passage comes somewhat earlier than the remark above. The passage runs: "And if we now settle by definition:

$$\begin{aligned} & [a + (b + 1) \stackrel{\alpha}{=} (a + b) + 1] \ \& \ [a + (b + (c + 1)) \stackrel{\beta}{=} (a + (b + c)) + 1] \ \& \\ & \& \ [(a + b) + (c + 1) \stackrel{\gamma}{=} \\ & = ((a + b) + c) + 1]. \stackrel{\text{Def}}{=} a + (b + c). \mathfrak{S}. (a + b) + c \dots U) \\ & \text{and in general: } [f_1(1) \stackrel{\rho}{=} f_2(1)] \ \& \ [f_1(c + 1) \stackrel{\beta}{=} f_1(c) + 1] \ \& \\ & \& \ [f_2(c + 1) \stackrel{\gamma}{=} f_2(c) + 1]. \stackrel{\text{Def}}{=} (f_1(c). \mathfrak{S}. f_2(c) \dots V)'' \end{aligned}$$

" \mathfrak{S} " is mentioned in the context below. V here is a definition of \mathfrak{S}). (Ed.)

Page 418

†1. The schema R above, p. 414. In the manuscript shortly after this schema there follows the remark:

"I have put a bracket } between α , β , γ and A, as if it was self-evident what this bracket meant. One might conjecture that the bracket meant the same as an equals sign. Such a bracket, incidentally, might be put

between " $1 \cdot 0/3 = 0 \cdot 3$ " and " $1 : 3 = 0 \cdot 3$ ".

Page 419

†1. Earlier version:... the question "is that too right?"

Page 420

†1. See below, p. 426.

Page 420

†2. Compare the form of the rule R on p. 433 below. In the manuscript Wittgenstein introduced this formulation thus: "Perhaps the matter will become clearer, if we give the following rule for addition instead of the recursive rule 'a + (b + 1) = (a + b) + 1'

$$\begin{aligned} a + (1 + 1) &= (a + 1) + 1 \\ a + (1 + 1) + 1 &= ((a + 1) + 1) + 1 \text{ [[sic, missing (]]} \\ a + (((1 + 1) + 1) + 1) &= (((a + 1) + 1) + 1) + 1 \\ &\dots \text{ etc....} \end{aligned}$$

Footnote Page Break 421

$$\left| \begin{array}{ccc} a + (a + 1) = (a + 1) + 1 & & \\ \downarrow & & \downarrow \\ a + (\xi + 1) & (a + \xi) + 1 & \\ a + ((\xi + 1) + 1) & ((a + \xi) + 1) + 1 & \end{array} \right| \mathbf{R}$$

We write this rule in the form, |1, ξ , $\xi + 1$ | thus
In the application of the rule R... a ranges over the series |1, ξ , $\xi + 1$ |."

Page 421

He then says of *this* rule that it can be written also in the form S or in the form a + (b + 1) = (a + b) + 1.

Page 433

†1. Cf. footnote, p. 420.

Page 439

Note on the Second Impression

There are a few alterations, taken from the text of the Blue Book in the possession of Mr. P. Sraffa. With the exception of changes on pp. 1 and 17 they make no difference to the sense, being mostly improvements in punctuation or grammar.

We rejected such changes as were no improvement.

The text of the Second Edition remains unaltered, but an index has been added.

All rights reserved. Except for the quotation of short passages for the purposes of criticism and review, no part of this publication may be reproduced, stored in a retrieval system, or transmitted, in any form or by any means, electronic, mechanical, photocopying, recording or otherwise, without the prior permission of the publisher.

Except in the United States of America, this book is sold subject to the condition that it shall not, by way of trade or otherwise, be lent, re-sold, hired out, or otherwise circulated without the publisher's prior consent in any form of binding or cover other than that in which it is published and without a similar condition including this condition being imposed on the subsequent purchaser.

PREFACE

Page v

WITTGENSTEIN dictated the "Blue Book" (though he did not call it that) to his class in Cambridge during the session 1933-34, and he had stencilled copies made. He dictated the "Brown Book" to two of his pupils (Francis Skinner and Alice Ambrose) during 1934-35. He had only three typed copies made of this, and he showed them only to very close friends and pupils. But people who borrowed them made their own copies, and there was a trade in them. If Wittgenstein had named these dictations, he might have called them "Philosophical Remarks" or

"Philosophical Investigations". But the first lot was bound in blue wrappers and the second in brown, and they were always spoken of that way.

Page v

He sent a copy of the Blue Book to Lord Russell later on, with a covering note.

DEAR RUSSELL,

Two years ago, or so, I promised to send you a manuscript of mine. Now the one I am sending you to-day isn't *that* manuscript. I'm still pottering about with it, and God knows whether I will ever publish it, or any of it. But two years ago I held some lectures in Cambridge and dictated some notes to my pupils so that they might have something to carry home with them, in their hands if not in their brains. And I had these notes duplicated. I have just been correcting misprints and other mistakes in some of the copies and the idea came into my mind whether you might not like to have a copy. So I'm sending you one. I don't wish to suggest that you should read the lectures; but *if* you should have nothing better to do and *if* you should get some mild enjoyment out of them I should be very pleased indeed. (I think it's very difficult to understand them, as so many points are just hinted at. They are meant only for the people who heard the lectures.) As I say, if you don't read them *it doesn't matter at all*.

Yours ever,

LUDWIG WITTGENSTEIN.

Page v

That was all the Blue Book was, though: a set of notes. The Brown Book was rather different, and for a time he thought of it as a draft of something he might publish. He started more than once to make revisions of a German version of it. The last was in August, 1936. He brought this, with some minor changes and insertions, to the beginning of the discussion of voluntary action--about page 154 in

Page Break vi

our text. Then he wrote, in heavy strokes, "Dieser ganze 'Versuch einer Umarbeitung' vom (Anfang) bis hierher ist *nichts wert*". ("This whole attempt at a revision, from the start right up to this point, is *worthless*.") That was when he began what we now have (with minor revisions) as the first part of the *Philosophical Investigations*.

Page vi

I doubt if he would have published the Brown Book in English, whatever happened. And anyone who can read his German will see why. His English style is often clumsy and full of Germanisms. But we have left it that way, except in a very few cases where it marred the sense and the correction was obvious. What we are printing here are notes he gave to his pupils, and a draft for his own use; that is all.

Page vi

Philosophy was a method of investigation, for Wittgenstein, but his conception of the method was changing. We can see this in the way he uses the notion of "language games", for instance. He used to introduce them in order to shake off the idea of a necessary form of language. At least that was one use he made of them, and one of the earliest. It is often useful to imagine different language games. At first he would sometimes write "different forms of language"--as though that were the same thing; though he corrected it in later versions, sometimes. In the Blue Book he speaks sometimes of imagining different language games, and sometimes of imagining different *notations*--as though that were what it amounted to. And it looks as though he had not distinguished clearly between being able to speak and understanding a notation.

Page vi

He speaks of coming to understand what people mean by having someone explain the meanings of the words, for instance. As though "understanding" and "explaining" were somehow correlative. But in the Brown Book he emphasizes that learning a language game is something prior to that. And what is needed is not explanation but *training*--comparable with the training you would give an animal. This goes with the point he emphasizes in the *Investigations*, that being able to speak and understand what is said--knowing what it means--does not mean that you can *say* what it means; nor is that what you have learned. He says there too (*Investigations*, par. 32) that "Augustine describes the learning of human language as if the child came into a strange country and did not understand the language of the country; that is, as if it already had a language, only not this one". You might see whether the child knows French by asking him what the expressions mean. But that is not how you tell whether a child can speak. And it is not what he learns when he learns to speak.

Page Break vii

Page vii

When the Brown Book speaks of different language games as "systems of communication" (Systeme menschlicher Verständigung), these are not just different notations. And this introduces a notion of understanding, and of the relation of understanding and language, which does not come to the front in the Blue Book at all. In the Brown Book he is insisting, for example, that "understanding" is not one thing; it is as various as the language games

themselves are. Which would be one reason for saying that when we do imagine different language games, we are not imagining parts or possible parts of any general system of language.

Page vii

The Blue Book is less clear about that. On page 17 he says that "the study of language games is the study of primitive forms of language or primitive languages". But then he goes on, "If we want to study the problems of truth and falsehood, of the agreement and disagreement of propositions with reality, of the nature of assertion, assumption and question, we shall with great advantage look at primitive forms of language in which these forms of thinking appear without the confusing background of highly complicated processes of thought. When we look at such simple forms of language, the mental mist which seems to enshroud our ordinary use of language disappears. We see activities, reactions, which are clear-cut and transparent. On the other hand we recognize in these simple processes forms of language not separated by a break from our more complicated ones. We see that we can build up the complicated forms from the primitive ones by gradually adding new forms."

Page vii

That almost makes it look as though we were trying to give something like an analysis of our ordinary language. As though we wanted to discover something that goes on in our language as we speak it, but which we cannot see until we take this method of getting through the mist that enshrouds it. And as if "the nature of assertion, assumption and question" were the same there; we have just found a way of making it transparent. Whereas the Brown Book is denying that. That is why he insists in the Brown Book (p. 81) that he is "not regarding the language games which we describe as incomplete parts of a language, but as languages complete in themselves". So that, for instance, certain grammatical functions in one language would not have any counterpart in another at all. And "agreement or disagreement with reality" would be something different in the different languages--so that the study of it in that language might not show you much about what it is in this one. That is why he asks in the

Page Break viii

Brown Book whether "Brick" means the same in the primitive language as it does in ours; this goes with his contention that the simpler language is not an incomplete form of the more complicated one. That discussion of whether we have to do here with an elliptical sentence is an important part of his account of what different language games are. But there is not even an anticipation of it in the Blue Book.

Page viii

In one of Wittgenstein's note-books there is a remark about language games, which he must have written at the beginning of 1934. I suspect it is later than the one I have quoted from page 17; anyway, it is different. "Wenn ich bestimmte einfache Sprachspiele beschreibe, so geschieht es nicht, um mit ihnen nach und nach die Vorgänge der ausgebildeten Sprache--oder des Denkens--aufzubauen, was nur zu Ungerechtigkeiten führt (Nicod und Russell),--sondern ich stelle die Spiele als solche hin, und lasse sie ihre aufklärende Wirkung auf die besonderen Probleme ausstrahlen." ("When I describe certain simple language games, this is not in order to construct from them gradually the processes of our developed language--or of thinking--which only leads to injustices (Nicod and Russell). I simply set forth the games as what they are, and let them shed their light on the particular problems.")

Page viii

I think that would be a good description of the method in the first part of the Brown Book. But it also points to the big difference between the Brown Book and the *Investigations*.

Page viii

In the Brown Book the account of the different language games is not directly a discussion of particular philosophical problems, although it is intended to throw light on them. It throws light on various aspects of language, especially--aspects to which we are often blinded just by the tendencies that find their sharpest expression in the problems of philosophy. And in this way the discussion does suggest where it is that the difficulties arise which give birth to those problems.

Page viii

For instance, in what he says about "can", and the connection between this and "seeing what is common", he is raising the question of what it is that you learn when you learn the language; or of what you know when you know what something means. But he is also raising the question of what it would mean to ask how the language *can* be developed--"Is that still something that has sense? Are you still speaking now, or is it gibberish?" And this may lead on to the question of "What can be said", or again of "How we should know it was a proposition"; or what a proposition is, or what language is. The way in which he describes the language games here is intended

Page Break ix

to show that one *need* not be led into asking those questions, and that it would be a misunderstanding if one were. But the trouble is that we are left wondering why people constantly *are*. And in this the *Investigations* is different.

The language games there (in the *Investigations*) are not stages in the exposition of a more complicated language, any more than they are in the Brown Book; less so, if anything. But they are stages in a discussion leading up to the "big question" of what language is (in par. 65).

He brings them in--in the *Investigations* and in the Brown Book too--to throw light on the question about the relation of words and what they stand for. But in the *Investigations* he is concerned with "the philosophical conception of meaning" which we find in Augustine, and he shows that this is the expression of a tendency which comes out most plainly in that theory of logically proper names which holds that the only *real* names are the demonstratives *this* and *that*. He calls this "a tendency to sublime the logic of our language" (die Logik unserer Sprache zu sublimieren) (par. 38)--partly because, in comparison with the logically proper names, "anything else we might call a name was one only in an inexact, approximate sense". It is this tendency which leads people to talk about the ultimate nature of language, or the logically correct grammar. But why should people fall into it? There is no simple answer, but Wittgenstein begins an answer here by going on to discuss the notions of "simple" and "complex" and the idea of logical analysis. (He does not do this in the Brown Book at all; and if all he wanted were to throw light on the functioning of language, there would be no need to.)

The whole idea of a logical analysis of language, or the logical analysis of propositions, is a queer and confused one. And in setting forth his language games Wittgenstein was not trying to give any analysis at all. If we call them "more primitive" or "simpler" languages, that does not mean that they reveal anything like the elements which a more complicated language must have. (Cf. *Investigations*, par. 64.) They are different languages--not elements or aspects of "Language". But then we may want to ask what there is about them that makes us say that they *are* all languages. What makes anything a language, anyway? And that is the "big question" (par. 65) about the nature of language or the nature of the proposition, which has lain behind the whole discussion up to this point.

We might even say that the discussion up to this point in the *Investigations* has been an attempt to bring out the sense of treating philosophical

problems by reference to language games at all. Or perhaps better: to show how the use of language games can make clear what a philosophical problem is.

In the Brown Book, on the other hand, he passes from examples of different sorts of naming to a discussion of various ways of "comparing with reality". This is still a discussion of the relations of words and what they stand for, no doubt. But he is not trying here to bring out the tendency behind that way of looking at words which has given trouble in philosophy.

In the *Investigations* he goes on then to a discussion of the relations of logic and language, but he does not do that in the Brown Book--although it is closely connected with what he says there. I mean especially what he says there about "can", and the connection of that with the idea of what can be said. ("When do we say that this is still language? When do we say it is a proposition?") For the temptation then is to think of a calculus, and of what can be said in it. But Wittgenstein would call that a misunderstanding of what a rule of language is, and of what using language is. When we speak as we generally do, we are not using precisely definable concepts, nor precise rules either. And the intelligibility is something different from intelligibility in a calculus.

It was because people thought of "what can be said" as "what is allowed in a calculus" ("For what other sense of 'allowed' is there?")--it was for that reason that logic was supposed to govern the *unity* of language: what belongs to language and what does not; what is intelligible and what is not; what is a proposition and what is not. In the Brown Book Wittgenstein is insisting that language does not have *that* kind of unity. Nor that kind of intelligibility. But he does not really discuss why people have wanted to suppose that it has.

You might think he had done that earlier, in the Blue Book, but I do not think he did. I do not think he sees the question about logic and language there which the Brown Book is certainly bringing out, even if it does not make quite clear what kind of difficulty it is. On page 25 of the Blue Book he says that "in general we don't use language according to strict rules--it hasn't been taught us by means of strict rules, either. *We*, in our discussions on the other hand, constantly compare language with a calculus proceeding according to exact rules." When he asks (at the bottom of the page) *why* we do this, he replies simply, "The answer is that the puzzles which we try to remove

always spring from just this attitude towards language". And

Page Break xi

you might wonder whether that *is* an answer. His point, as he puts it on page 27, for instance, is that "the man who is philosophically puzzled sees a law in the way a word is used, and, trying to apply this law consistently, comes up against... paradoxical results". And at first that looks something like what he said later, in the *Investigations*, about a tendency to sublime the logic of our language. But here in the Blue Book he does not bring out what there is about the use of language or the understanding of language that *leads* people to think of words in that way. Suppose we say that it is because philosophers look on language metaphysically. All right; but when we ask what makes them do *that*, Wittgenstein answers in the Blue Book that it is because of a craving for generality, and because "philosophers constantly see the method of science before their eyes, and are irresistibly tempted to ask and answer questions in the way science does" (p. 18). In other words, he does not find the source of metaphysics in anything specially connected with language. That is one very important point here, and it means that he was not anything like as clear about the character of philosophical puzzlement as he was when he wrote the *Investigations*. But in any case, it is not that tendency--to ask and answer questions in the way science does--or it is not primarily that, which leads philosophers to think of an ideal language or of a logically correct grammar when they are puzzled about language or about understanding. That comes in a different way.

Page xi

Wittgenstein is quite clear in the Blue Book that we do not use language according to strict rules, and that we do not use words according to laws like the laws that science speaks of. But he is not quite clear about the notions of "knowing the meaning" or of "understanding"; and that means that he is still unclear about a great deal in the notion of "following a rule" too. And for that reason he does not altogether recognize the kind of confusions that there may be when people say that knowing the language is knowing what *can* be said.

Page xi

"What does the *possibility* of the meanings of our words depend on?" That is what is behind the idea of meaning that we find in the theory of logically proper names and of logical analysis. And it goes with a question of what you learn when you learn the language; or of what learning the language is. Wittgenstein makes it plain in the Blue Book that words have the meanings we give them, and that it would be a confusion to think of an investigation into their *real* meanings. But he has not yet seen clearly the difference between learning a

Page Break xii

language game and learning a notation. And for that reason he cannot quite make out the character of the confusion he is opposing.

Page xii

In other words, in the Blue Book Wittgenstein had not seen clearly what the question about the requirements of language or the intelligibility of language is. That is why he can say, on page 28, that "ordinary language is all right". Which is like saying "it is a language, all right". And that seems to mean that it satisfies the requirements. But when he speaks like that, he is himself in the sort of confusion that he later brought out. And it seems to me to obscure the point of ideal languages--to obscure what those who spoke of them were trying to do--if one speaks, as Wittgenstein does here, as though "making up ideal languages" were what he was doing when he made up language games. He would not have spoken that way later.

Page xii

It may be this same unclarity, or something akin to it, that leads Wittgenstein to speak more than once in the Blue Book of "the calculus of language" (e.g. p. 42, top paragraph; or, better, p. 65, middle paragraph and last line)--although he has also said that it is only in very rare cases that we use language as a calculus. If you have not distinguished between a language and a notation, you may hardly see any difference between following a language and following a notation. But in that case you may well be unclear about the difficulties in connection with the relation between language and logic.

Page xii

Those difficulties become much clearer in the Brown Book, even though he does not explicitly refer to them there. We might say that they are the principal theme of the *Investigations*.

Page xii

For that is the theme that underlies the discussions of "seeing something as something" as well as the earlier parts. And once again we find that Wittgenstein in the *Investigations* is making these discussions into an exposition of the philosophical difficulties, in a way that he has not done in the Brown Book.

Page xii

At one time Wittgenstein was interested in the question of what it is to "recognize it as a proposition" (even

though it may be entirely unfamiliar), or to recognize something as language--to recognize that that is something written there, for instance--independently of your recognition of what it says. The second part of the Brown Book bears on this. And it shows that when such "recognitions" are rightly seen, they should not lead to the kinds of questions that philosophers have asked. The analogies that he draws between understanding a sentence and understanding a musical theme, for instance; or between wanting to say that this sentence means something and wanting to

Page Break xiii

say that this colour pattern says something--show clearly that it is not as though you were recognizing any *general* character (of intelligibility, perhaps) and that you ought to be able to tell us what that is, any more than it would make sense for you to ask me what the colour pattern does say.

Page xiii

But why *have* people wanted to speak of "meta-logic" in this connection, for instance? The Brown Book does something to explain that, and hints at more. But there is something about the way in which we use language, and in the connection of language and thinking--the force of an argument, and the force of expressions generally--which makes it seem as though recognizing it as a language were very different even from recognizing it as a move in a game. (As though understanding were something outside the signs; and as though to be a language it needs something that does not appear in the system of signs themselves.) And in the last sections of the *Investigations* he is trying to take account of this.

Page xiii

He had spoken of "operating with signs". And someone might say, "You make it look just like operating a mechanism; like any other mechanism. And if that is all there is to it--just the mechanism--then it is not a language." Well, there is no short answer to that. But it is an important question. So is the question of what we mean by "thinking *with* signs", for instance. What is that? And is the reference to making pencil strokes on paper really helpful?

Page xiii

Much of all this can be answered by emphasizing that speaking and writing belong to intercourse with other people. The signs get their life there, and that is why the language is not just a mechanism.

Page xiii

But the objection is that someone might do all that, make the signs correctly in the "game" with other people and get along all right, even if he were "meaning-blind". Wittgenstein used that expression in analogy with "colour-blind" and "tone-deaf". If I say an ambiguous word to you, like "board", for instance, I may ask you what meaning you think of when you hear it, and you may say that you think of a committee like the Coal Board, or perhaps you do not but think of a plank. Well, could we not imagine someone who could make no sense of such a question? If you just said a word to him like that, it gave him no meaning. And yet he could "react with words" to the sentences and other utterances he encountered, and to situations too, and react correctly. Or can we *not* imagine that? Wittgenstein was not sure, I think. If a man were "meaning-blind", would that make

Page Break xiv

any difference to his use of language? Or does the perception of meaning fall outside the use of language?

Page xiv

There is something wrong about that last question; something wrong about *asking* it. But it seems to show that there is still something unclear in our notion of "the use of language".

Page xiv

Or again, if we simply emphasize that signs belong to intercourse with people, what are we going to say about the role of "insight" in connection with mathematics and the discovery of proofs, for instance?

Page xiv

So long as there are such difficulties, people will still think that there must be something like an interpretation. They will still think that if it is language then it must mean something to *me*. And so on. And for this reason--in order to try to understand the kinds of difficulties these are--it was necessary for Wittgenstein to go into the whole complicated matter of "seeing something as something" in the way he was doing.

Page xiv

And the method has to be somewhat different there. One cannot do so much with language games.

Page Break xv

THE BLUE BOOK

Page xv

Page Break xvi

Page Break 1

Page 1

THE BLUE BOOK

Page 1

WHAT is the meaning of a word?

Page 1

Let us attack this question by asking, first, what is an explanation of the meaning of a word; what does the explanation of a word look like?

Page 1

The way this question helps us is analogous to the way the question "how do we measure a length?" helps us to understand the problem "what is length?"

Page 1

The questions "What is length?", "What is meaning?", "What is the number one?" etc., produce in us a mental cramp. We feel that we can't point to anything in reply to them and yet ought to point to something. (We are up against one of the great sources of philosophical bewilderment: a substantive makes us look for a thing that corresponds to it.)

Page 1

Asking first "What's an explanation of meaning?" has two advantages. You in a sense bring the question "what is meaning?" down to earth. For, surely, to understand the meaning of "meaning" you ought also to understand the meaning of "explanation of meaning". Roughly: "let's ask what the explanation of meaning is, for whatever that explains will be the meaning." Studying the grammar of the expression "explanation of meaning" will teach you something about the grammar of the word "meaning" and will cure you of the temptation to look about you for some object which you might call "the meaning".

Page 1

What one generally calls "explanations of the meaning of a word" can, *very roughly*, be divided into verbal and ostensive definitions. It will be seen later in what sense this division is only rough and provisional (and that it is, is an important point). The verbal definition, as it takes us from one verbal expression to another, in a sense gets us no further. In the ostensive definition however we seem to make a much more real step towards learning the meaning.

Page 1

One difficulty which strikes us is that for many words in our language there do not seem to be ostensive definitions; e.g. for such words as "one", "number", "not", etc.

Page 1

Question: Need the ostensive definition itself be understood?--Can't the ostensive definition be misunderstood?

Page Break 2

Page 2

If the definition explains the meaning of a word, surely it can't be essential that you should have heard the word before. It is the ostensive definition's business to *give* it a meaning. Let us then explain the word "tove" by pointing to a pencil and saying "this is tove". (Instead of "this is tove" I could here have said "this is called 'tove' ". I point this out to remove, once and for all, the idea that the words of the ostensive definition predicate something of the defined; the confusion between the sentence "this is red", attributing the colour red to something, and the ostensive definition "this is called 'red'".) Now the ostensive definition "this is tove" can be interpreted in all sorts of ways. I will give a few such interpretations and use English words with well established usage. The definition then can be interpreted to mean:

"This is a pencil",
"This is round",
"This is wood",
"This is one",
"This is hard", etc. etc.

Page 2

One might object to this argument that all these interpretations presuppose another word-language. And this

objection is significant if by "interpretation" we only mean "translation into a word-language".--Let me give some hints which might make this clearer. Let us ask ourselves what is our criterion when we say that someone has interpreted the ostensive definition in a particular way. Suppose I give to an Englishman the ostensive definition "this is what the Germans call 'Buch'". Then, in the great majority of cases at any rate, the English word "book" will come into the Englishman's mind. We may say he has interpreted "Buch" to mean "book". The case will be different if e.g. we point to a thing which he has never seen before and say: "This is a banjo". Possibly the word "guitar" will then come into his mind, possibly no word at all but the image of a similar instrument, possibly nothing at all. Supposing then I give him the order "now pick a banjo from amongst these things." If he picks what we call a "banjo" we might say "he has given the word 'banjo' the correct interpretation"; if he picks some other instrument--"he has interpreted 'banjo' to mean 'string instrument'".

Page 2

We say "he has given the word 'banjo' this or that interpretation", and are inclined to assume a definite act of interpretation besides the act of choosing.

Page Break 3

Page 3

Our problem is analogous to the following:

Page 3

If I give someone the order "fetch me a red flower from that meadow", how is he to know what sort of flower to bring, as I have only given him a *word*?

Page 3

Now the answer one might suggest first is that he went to look for a red flower carrying a red image in his mind, and comparing it with the flowers to see which of them had the colour of the image. Now there is such a way of searching, and it is not at all essential that the image we use should be a mental one. In fact the process may be this: I carry a chart co-ordinating names and coloured squares. When I hear the order "fetch me etc." I draw my finger across the chart from the word "red" to a certain square, and I go and look for a flower which has the same colour as the square. But this is not the only way of searching and it isn't the usual way. We go, look about us, walk up to a flower and pick it, without comparing it to anything. To see that the process of obeying the order can be of this kind, consider the order "*imagine* a red patch". You are not tempted in this case to think that *before* obeying you must have imagined a red patch to serve you as a pattern for the red patch which you were ordered to imagine.

Page 3

Now you might ask: do we *interpret* the words before we obey the order? And in some cases you will find that you do something which might be called interpreting before obeying, in some cases not.

Page 3

It seems that there are *certain definite* mental processes bound up with the working of language, processes through which alone language can function. I mean the processes of understanding and meaning. The signs of our language seem dead without these mental processes; and it might seem that the only function of the signs is to induce such processes, and that these are the things we ought really to be interested in. Thus, if you are asked what is the relation between a name and the thing it names, you will be inclined to answer that the relation is a psychological one, and perhaps when you say this you think in particular of the mechanism of association.--We are tempted to think that the action of language consists of two parts; an inorganic part, the handling of signs, and an organic part, which we may call understanding these signs, meaning them, interpreting them, thinking. These latter activities seem to take place in a queer kind of medium, the mind; and the mechanism of the mind, the nature of which, it seems, we don't quite understand, can bring about effects which no material mechanism could. Thus e.g. a thought (which is such a mental

Page Break 4

process) can agree or disagree with reality; I am able to think of a man who isn't present; I am able to imagine him, 'mean him' in a remark which I make about him, even if he is thousands of miles away or dead. "What a queer mechanism," one might say, "the mechanism of wishing must be if I can wish that which will never happen".

Page 4

There is one way of avoiding at least partly the occult appearance of the processes of thinking, and it is, to replace in these processes any working of the imagination by acts of looking at real objects. Thus it may seem essential that, at least in certain cases, when I hear the word "red" with understanding, a red image should be before my mind's eye. But why should I not substitute seeing a red bit of paper for imagining a red patch? The visual image will only be the more vivid. Imagine a man always carrying a sheet of paper in his pocket on which the names of colours are co-ordinated with coloured patches. You may say that it would be a nuisance to carry such a table of

samples about with you, and that the mechanism of association is what we always use instead of it. But this is irrelevant; and in many cases it is not even true. If, for instance, you were ordered to paint a particular shade of blue called "Prussian Blue", you might have to use a table to lead you from the word "Prussian Blue" to a sample of the colour, which would serve you as your copy.

Page 4

We could perfectly well, for our purposes, replace every process of imagining by a process of looking at an object or by painting, drawing or modelling; and every process of speaking to oneself by speaking aloud or by writing.

Page 4

Frege ridiculed the formalist conception of mathematics by saying that the formalists confused the unimportant thing, the sign, with the important, the meaning. Surely, one wishes to say, mathematics does not treat of dashes on a bit of paper. Frege's idea could be expressed thus: the propositions of mathematics, if they were just complexes of dashes, would be dead and utterly uninteresting, whereas they obviously have a kind of life. And the same, of course, could be said of any proposition: Without a sense, or without the thought, a proposition would be an utterly dead and trivial thing. And further it seems clear that no adding of inorganic signs can make the proposition live. And the conclusion which one draws from this is that what must be added to the dead signs in order to make a live proposition is something immaterial, with properties different from all mere signs.

Page 4

But if we had to name anything which is the life of the sign, we should have to say that it was its *use*.

Page Break 5

Page 5

If the meaning of the sign (roughly, that which is of importance about the sign) is an image built up in our minds when we see or hear the sign, then first let us adopt the method we just described of replacing this mental image by some outward object seen, e.g. a painted or modelled image. Then why should the written sign plus this painted image be alive if the written sign alone was dead?—In fact, as soon as you think of replacing the mental image by, say, a painted one, and as soon as the image thereby loses its occult character, it ceases to seem to impart any life to the sentence at all. (It was in fact just the occult character of the mental process which you needed for your purposes.)

Page 5

The mistake we are liable to make could be expressed thus: We are looking for the use of a sign, but we look for it as though it were an object *co-existing* with the sign. (One of the reasons for this mistake is again that we are looking for a "thing corresponding to a substantive.")

Page 5

The sign (the sentence) gets its significance from the system of signs, from the language to which it belongs. Roughly: understanding a sentence means understanding a language.

Page 5

As a part of the system of language, one may say, the sentence has life. But one is tempted to imagine that which gives the sentence life as something in an occult sphere, accompanying the sentence. But whatever accompanied it would for us just be another sign.

Page 5

It seems at first sight that that which gives to thinking its peculiar character is that it is a train of mental states, and it seems that what is queer and difficult to understand about thinking is the processes which happen in the medium of the mind, processes possible only in this medium. The comparison which forces itself upon us is that of the mental medium with the protoplasm of a cell, say, of an amoeba. We observe certain actions of the amoeba, its taking food by extending arms, its splitting up into similar cells, each of which grows and behaves like the original one. We say "of what a queer nature the protoplasm must be to act in such a way", and perhaps we say that no physical mechanism could behave in this way, and that the mechanism of the amoeba must be of a totally different kind. In the same way we are tempted to say "the mechanism of the mind must be of a most peculiar kind to be able to do what the mind does". But here we are making two mistakes. For what struck *us* as being queer about thought and thinking was not at all that it had curious effects which

Page Break 6

we were not yet able to explain (causally). Our problem, in other words, was not a scientific one; but a muddle felt as a problem.

Page 6

Supposing we tried to construct a mind-model as a result of psychological investigations, a model which, as

we should say, would explain the action of the mind. This model would be part of a psychological theory in the way in which a mechanical model of the ether can be part of a theory of electricity. (Such a model, by the way, is always part of the *symbolism* of a theory. Its advantage may be that it can be taken in at a glance and easily held in the mind. It has been said that a model, in a sense, dresses up the pure theory; that the *naked* theory is sentences or equations. This must be examined more closely later on.)

Page 6

We may find that such a mind-model would have to be very complicated and intricate in order to explain the observed mental activities; and on this ground we might call the mind a queer kind of medium. But this aspect of the mind does not interest us. The problems which it may set are psychological problems, and the method of their solution is that of natural science.

Page 6

Now if it is not the causal connections which we are concerned with, then the activities of the mind lie open before us. And when we are worried about the nature of thinking, the puzzlement which we wrongly interpret to be one about the nature of a medium is a puzzlement caused by the mystifying use of our language. This kind of mistake recurs again and again in philosophy; e.g. when we are puzzled about the nature of time, when time seems to us a *queer thing*. We are most strongly tempted to think that here are things hidden, something we can see from the outside but which we can't look into. And yet nothing of the sort is the case. It is not new facts about time which we want to know. All the facts that concern us lie open before us. But it is the use of the substantive "time" which mystifies us. If we look into the grammar of that word, we shall feel that it is no less astounding that man should have conceived of a deity of time than it would be to conceive of a deity of negation or disjunction.

Page 6

It is misleading then to talk of thinking as of a "mental activity". We may say that thinking is essentially the activity of operating with signs. This activity is performed by the hand, when we think by writing; by the mouth and larynx, when we think by speaking; and if we think by imagining signs or pictures, I can give you no agent that thinks. If then you say that in such cases the mind thinks, I would only draw your attention to the fact that you are using a metaphor, that here

Page Break 7

the mind is an agent in a different sense from that in which the hand can be said to be the agent in writing.

Page 7

If again we talk about the locality where thinking takes place we have a right to say that this locality is the paper on which we write or the mouth which speaks. And if we talk of the head or the brain as the locality of thought, this is using the expression "locality of thinking" in a different sense. Let us examine what are the reasons for calling the head the place of thinking. It is not our intention to criticize this form of expression, or to show that it is not appropriate. What we must do is: understand its working, its grammar, e.g. see what relation this grammar has to that of the expression "we think with our mouth", or "we think with a pencil on a piece of paper".

Page 7

Perhaps the main reason why we are so strongly inclined to talk of the head as the locality of our thoughts is this: the existence of the words "thinking" and "thought" alongside of the words denoting (bodily) activities, such as writing, speaking, etc., makes us look for an activity, different from these but analogous to them, corresponding to the word "thinking". When words in our ordinary language have *prima facie* analogous grammars we are inclined to try to interpret them analogously; i.e. we try to make the analogy hold throughout.--We say, "The thought is not the same as the sentence; for an English and a French sentence, which are utterly different, can express the same thought". And now, as the sentences are *somewhere*, we look for a place for the thought. (It is as though we looked for the place of the king of which the rules of chess treat, as opposed to the places of the various bits of wood, the kings of the various sets.)--We say, "surely the thought is *something*; it is not nothing"; and all one can answer to this is, that the word "thought" has its *use*, which is of a totally different kind from the use of the word "sentence".

Page 7

Now does this mean that it is nonsensical to talk of a locality where thought takes place? Certainly not. This phrase has sense' if we give it sense. Now if we say "thought takes place in our heads", what is the sense of this phrase soberly understood? I suppose it is that certain physiological processes correspond to our thoughts in such a way that if we know the correspondence we can, by observing these processes, find the thoughts. But in what sense can the physiological processes be said to correspond to thoughts, and in what sense can we be said to get the thoughts from the observation of the brain?

Page 7

I suppose we imagine the correspondence to have been verified experimentally. Let us imagine such an experiment crudely. It

Page Break 8

consists in looking at the brain while the subject thinks. And now you may think that the reason why my explanation is going to go wrong is that of course the experimenter gets the thoughts of the subject only *indirectly* by being told them, the subject *expressing* them in some way or other. But I will remove this difficulty by assuming that the subject is at the same time the experimenter, who is looking at his own brain, say by means of a mirror. (The crudity of this description in no way reduces the force of the argument.)

Page 8

Then I ask you, is the subject-experimenter observing one thing or two things? (Don't say that he is observing one thing both from the inside and from the outside; for this does not remove the difficulty. We will talk of inside and outside later.†1) The subject-experimenter is observing a correlation of two phenomena. One of them he, perhaps, calls the *thought*. This may consist of a train of images, organic sensations, or on the other hand of a train of the various visual, tactual and muscular experiences which he has in writing or speaking a sentence.--The other experience is one of seeing his brain work. Both these phenomena could correctly be called "expressions of thought"; and the question "where is the thought itself?" had better, in order to prevent confusion, be rejected as nonsensical. If however we do use the expression "the thought takes place in the head", we have given this expression its meaning by describing the experience which would justify the *hypothesis* that the thought takes place in our heads, by describing the experience which we wish to call "observing thought in our brain".

Page 8

We easily forget that the word "locality" is used in many different senses and that there are many different kinds of statements about a thing which in a particular case, in accordance with general usage, we may call specifications of the locality of the thing. Thus it has been said of visual space that its place is in our head; and I think one has been tempted to say this, partly, by a grammatical misunderstanding.

Page 8

I can say: "in my visual field I see the image of the tree to the right of the image of the tower" or "I see the image of the tree in the middle of the visual field". And now we are inclined to ask "and where do you see the visual field?" Now if the "where" is meant to ask for a locality in the sense in which we have specified the locality of the image of the tree, then I would draw your attention to the fact that you have not yet given this question sense; that is, that you have been

Page Break 9

proceeding by a grammatical analogy without having worked out the analogy in detail.

Page 9

In saying that the idea of our visual field being located in our brain arose from a grammatical misunderstanding, I did not mean to say that we could not give sense to such a specification of locality. We could, e.g., easily imagine an experience which we should describe by such a statement. Imagine that we looked at a group of things in this room, and, while we looked, a probe was stuck into our brain and it was found that if the point of the probe reached a particular point in our brain, then a particular small part of our visual field was thereby obliterated. In this way we might co-ordinate points of our brain to points of the visual image, and this might make us say that the visual field was seated in such and such a place in our brain. And if now we asked the question "Where do you see the image of this book?" the answer could be (as above) "To the right of that pencil", or "In the left hand part of my visual field", or again: "Three inches behind my left eye".

Page 9

But what if someone said "I can assure you I feel the visual image to be two inches behind the bridge of my nose"; what are we to answer him? Should we say that he is not speaking the truth, or that there cannot be such a feeling? What if he asks us "do you know all the feelings there are? How do you know there isn't such a feeling?"

Page 9

What if the diviner tells us that when he holds the rod he *feels* that the water is five feet under the ground? or that he *feels* that a mixture of copper and gold is five feet under the ground? Suppose that to our doubts he answered: "You can estimate a length when you see it. Why shouldn't I have a different way of estimating it?"

Page 9

If we understand the idea of such an estimation, we shall get clear about the nature of our doubts about the statements of the diviner, and of the man who said he felt the visual image behind the bridge of his nose.

Page 9

There is the statement: "this pencil is five inches long", and the statement, "I feel that this pencil is five inches long", and we must get clear about the relation of the grammar of the first statement to the grammar of the second.

To the statement "I feel in my hand that the water is three feet under the ground" we should like to answer: "I don't know what this *means*". But the diviner would say: "Surely you know what it means. You know what 'three feet under the ground' means, and you know what 'I feel' means!" But I should answer him: I know what a word means *in certain contexts*. Thus I

Page Break 10

understand the phrase, "three feet under the ground", say, in the connections "The measurement has shown that the water runs three feet under the ground", "If we dig three feet deep we are going to strike water", "The depth of the water is three feet by the eye". But the use of the expression "a feeling in my hands of water being three feet under the ground" has yet to be explained to me.

Page 10

We could ask the diviner "how did you learn the meaning of the word 'three feet'? We suppose by being shown such lengths, by having measured them and such like. Were you also taught to talk of a feeling of water being three feet under the ground, a feeling, say, in your hands? For if not, what made you connect the word 'three feet' with a feeling in your hand?" Supposing we had been estimating lengths by the eye, but had never spanned a length. How could we estimate a length in inches by spanning it? I.e., how could we interpret the experience of spanning in inches? The question is: what connection is there between, say, a tactual sensation and the experience of measuring a thing by means of a yard rod? This connection will show us what it means to 'feel that a thing is six inches long'. Supposing the diviner said "I have never learnt to correlate depth of water under the ground with feelings in my hand, but when I have a certain feeling of tension in my hands, the words 'three feet' spring up in my mind." We should answer "This is a perfectly good explanation of what you mean by 'feeling the depth to be three feet', and the statement that you feel this will have neither more, nor less, meaning than your explanation has given it. And if experience shows that the actual depth of the water always agrees with the words '*n* feet' which come into your mind, your experience will be very useful for determining the depth of water".--But you see that the meaning of the words "I feel the depth of the water to be *n* feet" had to be explained; it was not known when the meaning of the words "*n* feet" in the ordinary sense (i.e. in the ordinary contexts) was known.--We don't say that the man who tells us he feels the visual image two inches behind the bridge of his nose is telling a lie or talking nonsense. But we say that we don't understand the meaning of such a phrase. It combines well-known words, but combines them in a way we don't yet understand. The grammar of this phrase has yet to be explained to us.

Page 10

The importance of investigating the diviner's answer lies in the fact that we often think we have given a meaning to a statement P if only we assert "I *feel* (or I believe) that P is the case." (We shall talk at a later

Page Break 11

occasion†1 of Prof. Hardy saying that Goldbach's theorem is a proposition because he can believe that it is true.) We have already said that by merely explaining the meaning of the words "three feet" in the usual way we have not yet explained the sense of the phrase "feeling that water is three feet etc." Now we should not have felt these difficulties had the diviner said that he had *learnt* to estimate the depth of the water, say, by digging for water whenever he had a particular feeling and in this way correlating such feelings with *measurements* of depth. Now we must examine the relation of the process of *learning to estimate* with the act of estimating. The importance of this examination lies in this, that it applies to the relation between learning the meaning of a word and making use of the word. Or, more generally, that it shows the different possible relations between a rule given and its application.

Page 11

Let us consider the process of estimating a length by the eye: It is extremely important that you should realise that there are a great many different processes which we call "estimating by the eye".

Page 11

Consider these cases:--

Page 11

- (1) Someone asks "How did you estimate the height of this building?" I answer: "It has four storeys; I suppose each storey is about fifteen feet high; so it must be about sixty feet."
- (2) In another case: "I roughly know what a yard at that distance looks like; so it must be about four yards long."
- (3) Or again: "I can imagine a tall man reaching to about this point; so it must be about six feet above the ground."
- (4) Or: "I don't know; it just looks like a yard."

Page 11

This last case is likely to puzzle us. If you ask "what happened in this case when the man estimated the length?" the correct answer may be: "he *looked* at the thing and *said* 'it looks one yard long'." This may be all that has happened.

Page 11

We said before that we should not have been puzzled about the diviner's answer if he had told us that he had *learnt* how to estimate depth. Now learning to estimate may, broadly speaking, be seen in two different relations to the act of estimating; either as a cause of the phenomenon of estimating, or as supplying us with a rule (a table, a chart, or some such thing) which we make use of when we estimate.

Page 11

Supposing I teach someone the use of the word "yellow" by repeatedly pointing to a yellow patch and pronouncing the word.

Page Break 12

On another occasion I make him apply what he has learnt by giving him the order, "choose a yellow ball out of this bag". What was it that happened when he obeyed my order? I say "possibly just this: he heard my words and took a yellow ball from the bag". Now you may be inclined to think that this couldn't possibly have been all; and the *kind* of thing that you would suggest is that he imagined something yellow when he *understood* the order, and then chose a ball according to his image. To see that this is not *necessary* remember that I could have given him the order, "Imagine a yellow patch". Would you still be inclined to assume that he first imagines a yellow patch, just *understanding* my order, and then imagines a yellow patch to match the first? (Now I don't say that this is not possible. Only, putting it in this way immediately shows you that it need not happen. This, by the way, illustrates the method of philosophy.)

Page 12

If we are taught the meaning of the word "yellow" by being given some sort of ostensive definition (a rule of the usage of the word) this teaching can be looked at in two different ways.

Page 12

A. The teaching is a drill. This drill causes us to associate a yellow image, yellow things, with the word "yellow". Thus when I gave the order "Choose a yellow ball from this bag" the word "yellow" might have brought up a yellow image, or a feeling of recognition when the person's eye fell on the yellow ball. The drill of teaching could in this case be said to have built up a psychical mechanism. This, however, would only be a hypothesis or else a metaphor. We could *compare* teaching with installing an electric connection between a switch and a bulb. The parallel to the connection going wrong or breaking down would then be what we call forgetting the explanation, or the meaning, of the word. (We ought to talk further on about the meaning of "forgetting the meaning of a word"†1).

Page 12

In so far as the teaching brings about the association, feeling of recognition, etc. etc., it is the *cause* of the phenomena of understanding, obeying, etc.; and it is a hypothesis that the process of teaching should be needed in order to bring about these effects. It is conceivable, in this sense, that *all* the processes of understanding, obeying, etc., should have happened without the person ever having been taught the language. (This, just now, seems extremely paradoxical.)

Page 12

B. The teaching may have supplied us with a rule which is itself involved in the processes of understanding, obeying, etc.; "involved",

Page Break 13

however, meaning that the expression of this rule forms part of these processes.

Page 13

We must distinguish between what one might call "a process being *in accordance with* a rule", and, "a process involving a rule" (in the above sense).

Page 13

Take an example. Some one teaches me to square cardinal numbers; he writes down the row

1 2 3 4,

and asks me to square them. (I will, in this case again, replace any processes happening 'in the mind' by processes of calculation on the paper.) Suppose, underneath the first row of numbers, I then write:

1 4 9 16.

What I wrote is in accordance with the general rule of squaring; but it obviously is also in accordance with any number of other rules; and amongst these it is not more in accordance with one than with another. In the sense in which before we talked about a rule being involved in a process, *no* rule was involved in this. Supposing that in order to get to my results I calculated 1×1 , 2×2 , 3×3 , 4×4 (that is, in this case wrote down the calculations); these

would again be in accordance with any number of rules. Supposing, on the other hand, in order to get to my results I had written down what you may call "the rule of squaring", say algebraically. In this case this rule was involved in a sense in which no other rule was.

Page 13

We shall say that the rule is *involved* in the understanding, obeying, etc., if, as I should like to express it, the symbol of the rule forms part of the calculation. (As we are not interested in where the processes of thinking, calculating, take place, we can for our purpose imagine the calculations being done entirely on paper. We are not concerned with the difference: internal, external.)

Page 13

A characteristic example of the case B would be one in which the teaching supplied us with a table which we actually make use of in understanding, obeying, etc. If we are taught to play chess, we may be taught rules. If then we play chess, these rules need not be involved in the act of playing. But they may be. Imagine, e.g., that the rules were expressed in the form of a table; in one column the shapes of the chessmen are drawn, and in a parallel column we find diagrams showing the 'freedom' (the legitimate moves) of the pieces. Suppose now that the way the game is played involves making the transition from

Page Break 14

the shape to the possible moves by running one's finger across the table, and then making one of these moves.

Page 14

Teaching as the hypothetical history of our subsequent actions (understanding, obeying, estimating a length, etc.) drops out of our considerations. The rule which has been taught and is subsequently applied interests us only so far as it is involved in the application. A rule, so far as it interests us, does not act at a distance.

Page 14

Suppose I pointed to a piece of paper and said to someone: "this colour I call 'red'". Afterwards I give him the order: "now paint me a red patch". I then ask him: "why, in carrying out my order, did you paint just this colour?" His answer could then be: "This colour (pointing to the sample which I have given him) was called red; and the patch I have painted has, as you see, the colour of the sample". He has now given me a reason for carrying out the order in the way he did. Giving a reason for something one did or said means showing a way which leads to this action. In some cases it means telling the way which one has gone oneself; in others it means describing a way which leads there and is in accordance with certain accepted rules. Thus when asked, "why did you carry out my order by painting just this colour?" the person could have described the way he had actually taken to arrive at this particular shade of colour. This would have been so if, hearing the word "red", he had taken up the sample I had given him, labelled "red", and had *copied* that sample when painting the patch. On the other hand he might have painted it 'automatically' or from a memory image, but when asked to give the reason he might still point to the sample and show that it matched the patch he had painted. In this latter case the reason given would have been of the second kind; i.e. a justification *post hoc*.

Page 14

Now if one thinks that there could be no understanding and obeying the order without a previous teaching, one thinks of the teaching as supplying a *reason* for doing what one did; as supplying the road one walks. Now there is the idea that if an order is understood and obeyed there must be a reason for our obeying it as we do; and, in fact, a chain of reasons reaching back to infinity. This is as if one said: "Wherever you are, you must have got there from somewhere else, and to that previous place from another place; and so on *ad infinitum*". (If, on the other hand, you had said, "wherever you are, you *could* have got there from another place ten yards away; and to that other place from a third, ten yards further away, and so on *ad infinitum*", if you had said this you would have stressed the infinite *possibility* of making a step.

Page Break 15

Thus the idea of an infinite chain of reasons arises out of a confusion similar to this: that a line of a certain length consists of an infinite number of parts because it is indefinitely divisible; i.e., because there is no end to the possibility of dividing it.)

Page 15

If on the other hand you realize that the chain of *actual* reasons has a beginning, you will no longer be revolted by the idea of a case in which there is *no* reason for the way you obey the order. At this point, however, another confusion sets in, that between reason and cause. One is led into this confusion by the ambiguous use of the word "why". Thus when the chain of reasons has come to an end and still the question "why?" is asked, one is inclined to give a cause instead of a reason. If, e.g., to the question, "why did you paint just this colour when I told you to paint a red patch?" you give the answer: "I have been shown a sample of this colour and the word 'red' was

pronounced to me at the same time; and therefore this colour now always comes to my mind when I hear the word 'red' ", then you have given a cause for your action and not a reason.

Page 15

The proposition that your action has such and such a cause, is a hypothesis. The hypothesis is well-founded if one has had a number of experiences which, roughly speaking, agree in showing that your action is the regular sequel of certain conditions which we then call causes of the action. In order to know the reason which you had for making a certain statement, for acting in a particular way, etc., no number of agreeing experiences is necessary, and the statement of your reason is not a hypothesis. The difference between the grammars of "reason" and "cause" is quite similar to that between the grammars of "motive" and "cause". Of the cause one can say that one can't *know* it but can only *conjecture* it. On the other hand one often says: "Surely *I* must know why I did it" talking of the *motive*. When I say: "we can only *conjecture* the cause but we *know* the motive" this statement will be seen later on to be a grammatical one. The "can" refers to a *logical* possibility.

Page 15

The double use of the word "why", asking for the cause and asking for the motive, together with the idea that we can know, and not only conjecture, our motives, gives rise to the confusion that a motive is a cause of which we are immediately aware, a cause 'seen from the inside', or a cause experienced.--Giving a reason is like giving a calculation by which you have arrived at a certain result.

Page 15

Let us go back to the statement that thinking essentially consists in operating with signs. My point was that it is liable to mislead us

Page Break 16

if we say 'thinking is a mental activity'. The question what kind of an activity thinking is is analogous to this: "Where does thinking take place?" We can answer: on paper, in our head, in the mind. None of these statements of locality gives *the* locality of thinking. The use of all these specifications is correct, but we must not be misled by the similarity of their linguistic form into a false conception of their grammar. As, e.g., when you say: "Surely, the *real* place of thought is in our head". The same applies to the idea of thinking as an activity. It is correct to say that thinking is an activity of our writing hand, of our larynx, of our head, and of our mind, so long as we understand the grammar of these statements. And it is, furthermore, extremely important to realize how, by misunderstanding the grammar of our expressions, we are led to think of one in particular of these statements as giving the *real* seat of the activity of thinking.

Page 16

There is an objection to saying that thinking is some such thing as an activity of the hand. Thinking, one wants to say, is part of our 'private experience'. It is not material, but an event in private consciousness. This objection is expressed in the question: "Could a machine think?" I shall talk about this at a later point,†1 and now only refer you to an analogous question: "Can a machine have toothache?" You will certainly be inclined to say: "A machine can't have toothache". All I will do now is to draw your attention to the use which you have made of the word "can" and to ask you: "Did you mean to say that all our past experience has shown that a machine never had toothache?" The impossibility of which you speak is a logical one. The question is: What is the relation between thinking (or toothache) and the subject which thinks, has toothache, etc.? I shall say no more about this now.

Page 16

If we say thinking is essentially operating with signs, the first question you might ask is: "What are signs?"--Instead of giving any kind of general answer to this question, I shall propose to you to look closely at particular cases which we should call "operating with signs". Let us look at a simple example of operating with words. I give someone the order: "fetch me six apples from the grocer", and I will describe a way of making use of such an order: The words "six apples" are written on a bit of paper, the paper is handed to the grocer, the grocer compares the word "apple" with labels on different shelves. He finds it to agree with one of the labels, counts from 1 to the number written on the slip of paper, and for every number counted

Page Break 17

takes a fruit off the shelf and puts it in a bag.--And here you have a case of the use of words. I shall in the future again and again draw your attention to what I shall call language games. These are ways of using signs simpler than those in which we use the signs of our highly complicated everyday language. Language games are the forms of language with which a child begins to make use of words. The study of language games is the study of primitive forms of language or primitive languages. If we want to study the problems of truth and falsehood, of the agreement and disagreement of propositions with reality, of the nature of assertion, assumption, and question, we shall with great

advantage look at primitive forms of language in which these forms of thinking appear without the confusing background of highly complicated processes of thought. When we look at such simple forms of language the mental mist which seems to enshroud our ordinary use of language disappears. We see activities, reactions, which are clear-cut and transparent. On the other hand we recognize in these simple processes forms of language not separated by a break from our more complicated ones. We see that we can build up the complicated forms from the primitive ones by gradually adding new forms.

Page 17

Now what makes it difficult for us to take this line of investigation is our craving for generality.

Page 17

This craving for generality is the resultant of a number of tendencies connected with particular philosophical confusions. There is

Page 17

(a) The tendency to look for something in common to all the entities which we commonly subsume under a general term.--We are inclined to think that there must be something in common to all games, say, and that this common property is the justification for applying the general term "game" to the various games; whereas games form a *family* the members of which have family likenesses. Some of them have the same nose, others the same eyebrows and others again the same way of walking; and these likenesses overlap. The idea of a general concept being a common property of its particular instances connects up with other primitive, too simple, ideas of the structure of language. It is comparable to the idea that *properties* are *ingredients* of the things which have the properties; e.g. that beauty is an ingredient of all beautiful things as alcohol is of beer and wine, and that we therefore could have pure beauty, unadulterated by anything that is beautiful.

Page 17

(b) There is a tendency rooted in our usual forms of expression,

Page Break 18

to think that the man who has learnt to understand a general term, say, the term "leaf", has thereby come to possess a kind of general picture of a leaf, as opposed to pictures of particular leaves. He was shown different leaves when he learnt the meaning of the word "leaf"; and showing him the particular leaves was only a means to the end of producing 'in him' an idea which we imagine to be some kind of general image. We say that he sees what is in common to all these leaves; and this is true if we mean that he can on being asked tell us certain features or properties which they have in common. But we are inclined to think that the general idea of a leaf is something like a visual image, but one which only contains what is common to all leaves. (Galtonian composite photograph.) This again is connected with the idea that the meaning of a word is an image, or a thing correlated to the word. (This roughly means, we are looking at words as though they all were proper names, and we then confuse the bearer of a name with the meaning of the name.)

Page 18

(c) Again, the idea we have of what happens when we get hold of the general idea 'leaf', 'plant', etc. etc., is connected with the confusion between a mental state, meaning a state of a hypothetical mental mechanism, and a mental state meaning a state of consciousness (toothache, etc.).

Page 18

(d) Our craving for generality has another main source: our preoccupation with the method of science. I mean the method of reducing the explanation of natural phenomena to the smallest possible number of primitive natural laws; and, in mathematics, of unifying the treatment of different topics by using a generalization. Philosophers constantly see the method of science before their eyes, and are irresistibly tempted to ask and answer questions in the way science does. This tendency is the real source of metaphysics, and leads the philosopher into complete darkness. I want to say here that it can never be our job to reduce anything to anything, or to explain anything. Philosophy really *is* 'purely descriptive'. (Think of such questions as "Are there sense data?" and ask: What method is there of determining this? Introspection?)

Page 18

Instead of "craving for generality" I could also have said "the contemptuous attitude towards the particular case". If, e.g., someone tries to explain the concept of number and tells us that such and such a definition will not do or is clumsy because it only applies to, say, finite cardinals I should answer that the mere fact that he could have given such a limited definition makes this definition extremely important to

Page Break 19

us. (Elegance is *not* what we are trying for.) For why should what finite and transfinite numbers have in common be more interesting to us than what distinguishes them? Or rather, I should not have said "why should it be more

interesting to us?"--it *isn't*; and this characterizes our way of thinking.

Page 19

The attitude towards the more general and the more special in logic is connected with the usage of the word "kind" which is liable to cause confusion. We talk of kinds of numbers, kinds of propositions, kinds of proofs; and, also, of kinds of apples, kinds of paper, etc. In one sense what defines the kind are properties, like sweetness, hardness, etc. In the other the different kinds are different grammatical structures. A treatise on pomology may be called incomplete if there exist kinds of apples which it doesn't mention. Here we have a standard of completeness in nature. Supposing on the other hand there was a game resembling that of chess but simpler, no pawns being used in it. Should we call this game incomplete? Or should we call a game more complete than chess if it in some way contained chess but added new elements? The contempt for what seems the less general case in logic springs from the idea that it is incomplete. It is in fact confusing to talk of cardinal arithmetic as something special as opposed to something more general. Cardinal arithmetic bears no mark of incompleteness; nor does an arithmetic which is cardinal and finite. (There are no subtle distinctions between logical forms as there are between the tastes of different kinds of apples.)

Page 19

If we study the grammar, say, of the words "wishing", "thinking", "understanding", "meaning", we shall not be dissatisfied when we have described various cases of wishing, thinking, etc. If someone said, "surely this is not all that one calls 'wishing'", we should answer, "certainly not, but you can build up more complicated cases if you like." And after all, there is not one definite class of features which characterize all cases of wishing (at least not as the word is commonly used). If on the other hand you wish to give a definition of wishing, i.e., to draw a sharp boundary, then you are free to draw it as you like; and this boundary will never entirely coincide with the actual usage, as this usage has no sharp boundary.

Page 19

The idea that in order to get clear about the meaning of a general term one had to find the common element in all its applications has shackled philosophical investigation; for it has not only led to no result, but also made the philosopher dismiss as irrelevant the concrete cases, which alone could have helped him to understand the usage of

Page Break 20

the general term. When Socrates asks the question, "what is knowledge?" he does not even regard it as a *preliminary* answer to enumerate cases of knowledge.†1 If I wished to find out what sort of thing arithmetic is, I should be very content indeed to have investigated the case of a finite cardinal arithmetic. For

Page 20

(a) this would lead me on to all the more complicated cases,

Page 20

(b) a finite cardinal arithmetic is not incomplete, it has no gaps which are then filled in by the rest of arithmetic.

Page 20

What happens if from 4 till 4.30 A expects B to come to his room? In one sense in which the phrase "to expect something from 4 to 4.30" is used it certainly does not refer to one process or state of mind going on throughout that interval, but to a great many different activities and states of mind. If for instance I expect B to come to tea, what happens *may* be this: At four o'clock I look at my diary and see the name "B" against today's date; I prepare tea for two; I think for a moment "does B smoke?" and put out cigarettes; towards 4.30 I begin to feel impatient; I imagine B as he will look when he comes into my room. All this is called "expecting B from 4 to 4.30". And there are endless variations to this process which we all describe by the same expression. If one asks what the different processes of expecting someone to tea have in common, the answer is that there is no single feature in common to all of them, though there are many common features overlapping. These cases of expectation form a family; they have family likenesses which are not clearly defined.

Page 20

There is a totally different use of the word "expectation" if we use it to mean a particular sensation. This use of the words like "wish", "expectation", etc., readily suggests itself. There is an obvious connection between this use and the one described above. There is no doubt that in many cases if we expect some one, in the first sense, some, or all, of the activities described are accompanied by a peculiar feeling, a tension; and it is natural to use the word "expectation" to mean this experience of tension.

Page 20

There arises now the question: is this sensation to be called "the sensation of expectation", or "the sensation of expectation that B will come"? In the first case to say that you are in a state of expectation admittedly does not fully describe the situation of expecting that so-and-so will happen. The second case is often rashly suggested as an

explanation of the use of the phrase "expecting that so-and-so will happen", and you may even think that with this explanation you are

Page Break 21

on safe ground, as every further question is dealt with by saying that the sensation of expectation is indefinable.

Page 21

Now there is no objection to calling a particular sensation "the expectation that B will come". There may even be good practical reasons for using such an expression. Only mark:--if we have explained the meaning of the phrase "expecting that B will come" in this way no phrase which is derived from this by substituting a different name for "B" is thereby explained. One might say that the phrase "expecting that B will come" is not a value of a function "expecting that x will come". To understand this compare our case with that of the function "I eat x ". We understand the proposition "I eat a chair" although we weren't specifically taught the meaning of the expression "eating a chair".

Page 21

The role which in our present case the name "B" plays in the expression "I expect B" can be compared with that which the name "Bright" plays in the expression "Bright's disease". †1 Compare the grammar of this word, when it denotes a particular kind of disease, with that of the expression "Bright's disease" when it means the disease which Bright has. I will characterize the difference by saying that the word "Bright" in the first case is an index in the complex *name* "Bright's disease"; in the second case I shall call it an argument of the function " x 's disease". One may say that an index *alludes* to something, and such an allusion may be justified in all sorts of ways. Thus calling a sensation "the expectation that B will come" is giving it a complex name and "B" possibly alludes to the man whose coming had regularly been preceded by the sensation.

Page 21

Again we may use the phrase "expectation that B will come" not as a name but as a characteristic of certain sensations. We might, e.g., explain that a certain tension is said to be an expectation that B will come if it is relieved by B's coming. If this is how we use the phrase then it is true to say that we don't know what we expect until our expectation has been fulfilled (cf. Russell). But no one can believe that this is the only way or even the most common way of using the word "expect". If I ask someone "whom do you expect?" and after receiving the answer ask again "Are you sure that you don't expect someone else?" then, in most cases, this question would be regarded as absurd, and the answer will be something like "Surely, I must know whom I expect".

Page 21

One may characterize the meaning which Russell gives to the word

Page Break 22

"wishing" by saying that it means to him a kind of hunger.--It is a hypothesis that a particular feeling of hunger will be relieved by eating a particular thing. In Russell's way of using the word "wishing" it makes no sense to say "I wished for an apple but a pear has satisfied me". †1 But we do sometimes say this, using the word "wishing" in a way different from Russell's. In this sense we can say that the tension of wishing was relieved without the wish being fulfilled; and also that the wish was fulfilled without the tension being relieved. That is, I may, in this sense, become satisfied without my wish having been satisfied.

Page 22

Now one might be tempted to say that the difference which we are talking about simply comes to this, that in some cases we know what we wish and in others we don't. There are certainly cases in which we say, "I feel a longing, though I don't know what I'm longing for" or, "I feel a fear, but I don't know what I'm afraid of", or again: "I feel fear, but I'm not afraid of anything in particular".

Page 22

Now we may describe these cases by saying that we have certain sensations not referring to objects. The phrase "not referring to objects" introduces a grammatical distinction. If in characterizing such sensations we use verbs like "fearing", "longing", etc., these verbs will be intransitive; "I fear" will be analogous to "I cry". We may cry about something, but what we cry about is not a constituent of the process of crying; that is to say, we could describe all that happens when we cry without mentioning what we are crying about.

Page 22

Suppose now that I suggested we should use the expression "I feel fear", and similar ones, in a transitive way only. Whenever before we said "I have a sensation of fear" (intransitively) we will now say "I am afraid of something, but I don't know of what". Is there an objection to this terminology?

We may say: "There isn't, except that we are then using the word 'to know' in a queer way". Consider this case:--we have a general undirected feeling of fear. Later on, we have an experience which makes us say, "Now I know what I was afraid of. I was afraid of so-and-so happening". Is it correct to describe my first feeling by an intransitive verb, or should I say that my fear had an object although I did not know that it had one? Both these forms of description can be used. To understand this examine the following example: It might be found practical to call a certain state of decay in a tooth, not accompanied by what we commonly call toothache, "unconscious

toothache" and to use in such a case the expression that we have toothache, but don't know it. It is in just this sense that psychoanalysis talks of unconscious thoughts, acts of volition, etc. Now is it wrong in this sense to say that I have toothache but don't know it? There is nothing wrong about it, as it is just a new terminology and can at any time be retranslated into ordinary language. On the other hand it obviously makes use of the word "to know" in a new way. If you wish to examine how this expression is used it is helpful to ask yourself "what in this case is the process of getting to know like?" "What do we call 'getting to know' or, 'finding out'?"

It isn't wrong, according to our new convention, to say "I have unconscious toothache". For what more can you ask of your notation than that it should distinguish between a bad tooth which doesn't give you toothache and one which does? But the new expression misleads us by calling up pictures and analogies which make it difficult for us to go through with our convention. And it is extremely difficult to discard these pictures unless we are constantly watchful; particularly difficult when, in philosophizing, we contemplate what we *say* about things. Thus, by the expression "unconscious toothache" you may either be misled into thinking that a stupendous discovery has been made, a discovery which in a sense altogether bewilders our understanding; or else you may be extremely puzzled by the expression (the puzzlement of philosophy) and perhaps ask such a question as "How is unconscious toothache possible?" You may then be tempted to deny the possibility of unconscious toothache; but the scientist will tell you that it is a proved fact that there is such a thing, and he will say it like a man who is destroying a common prejudice. He will say: "Surely it's quite simple; there are other things which you don't know of, and there can also be toothache which you don't know of. It is just a new discovery". You won't be satisfied, but you won't know what to answer. This situation constantly arises between the scientist and the philosopher.

In such a case we may clear the matter up by saying: "Let's see how the word 'unconscious', 'to know', etc. etc., is used in this case, and how it's used in others". *How far does the analogy between these uses go?* We shall also try to construct new notations, in order to break the spell of those which we are accustomed to.

We said that it was a way of examining the grammar (the use) of the word "to know", to ask ourselves what, in the particular case we are examining, we should call "getting to know". There is a temptation

to think that this question is only vaguely relevant, if relevant at all, to the question: "what is the meaning of the word 'to know'?" We seem to be on a side-track when we ask the question "What is it like in this case 'to get to know'?" But this question really is a question concerning the grammar of the word "to know", and this becomes clearer if we put it in the form: "What do we *call* 'getting to know'?" It is part of the grammar of the word "chair" that *this* is what we call "to sit on a chair", and it is part of the grammar of the word "meaning" that *this* is what we call "explanation of a meaning"; in the same way to explain my criterion for another person's having toothache is to give a grammatical explanation about the word "toothache" and, in this sense, an explanation concerning the meaning of the word "toothache".

When we learnt the use of the phrase "so-and-so has toothache" we were pointed out certain kinds of behaviour of those who were said to have toothache. As an instance of these kinds of behaviour let us take holding your cheek. Suppose that by observation I found that in certain cases whenever these first criteria told me a person had toothache, a red patch appeared on the person's cheek. Supposing I now said to someone "I see A has toothache, he's got a red patch on his cheek". He may ask me "How do you know A has toothache when you see a red patch?" I should then point out that certain phenomena had always coincided with the appearance of the red patch.

Now one may go on and ask: "How do you know that he has got toothache when he holds his cheek?" The

answer to this might be, "I say, *he* has toothache when he holds his cheek because I hold my cheek when I have toothache". But what if we went on asking:--"And why do you suppose that toothache corresponds to his holding his cheek just because your toothache corresponds to your holding your cheek?" You will be at a loss to answer this question, and find that here we strike rock bottom, that is we have come down to conventions. (If you suggest as an answer to the last question that, whenever we've seen people holding their cheeks and asked them what's the matter, they have answered, "I have toothache",-remember that this experience only co-ordinates holding your cheek with saying certain words.)

Page 24

Let us introduce two antithetical terms in order to avoid certain elementary confusions: To the question "How do you know that so-and-so is the case?", we sometimes answer by giving '*criteria*' and sometimes

Page Break 25

by giving '*symptoms*'. If medical science calls angina an inflammation caused by a particular bacillus, and we ask in a particular case "why do you say this man has got angina?" then the answer "I have found the bacillus so-and-so in his blood" gives us the criterion, or what we may call the defining criterion of angina. If on the other hand the answer was, "His throat is inflamed", this might give us a symptom of angina. I call "symptom" a phenomenon of which experience has taught us that it coincided, in some way or other, with the phenomenon which is our defining criterion. Then to say "A man has angina if this bacillus is found in him" is a tautology or it is a loose way of stating the definition of "angina". But to say, "A man has angina whenever he has an inflamed throat" is to make a hypothesis.

Page 25

In practice, if you were asked which phenomenon is the defining criterion and which is a symptom, you would in most cases be unable to answer this question except by making an arbitrary decision *ad hoc*. It may be practical to define a word by taking one phenomenon as the defining criterion, but we shall easily be persuaded to define the word by means of what, according to our first use, was a symptom. Doctors will use names of diseases without ever deciding which phenomena are to be taken as criteria and which as symptoms; and this need not be a deplorable lack of clarity. For remember that in general we don't use language according to strict rules-it hasn't been taught us by means of strict rules, either. *We*, in our discussions on the other hand, constantly compare language with a calculus proceeding according to exact rules.

Page 25

This is a very one-sided way of looking at language. In practice we very rarely use language as such a calculus. For not only do we not think of the rules of usage--of definitions, etc.--while using language, but when we are asked to give such rules, in most cases we aren't able to do so. We are unable clearly to circumscribe the concepts we use; not because we don't know their real definition, but because there is no real 'definition' to them. To suppose that there *must* be would be like supposing that whenever children play with a ball they play a game according to strict rules.

Page 25

When we talk of language as a symbolism used in an exact calculus, that which is in our mind can be found in the sciences and in mathematics. Our ordinary use of language conforms to this standard of exactness only in rare cases. Why then do we in philosophizing constantly compare our use of words with one following exact rules?

Page Break 26

The answer is that the puzzles which we try to remove always spring from just this attitude towards language.

Page 26

Consider as an example the question "What is time?" as Saint Augustine and others have asked it. At first sight what this question asks for is a definition, but then immediately the question arises: "What should we gain by a definition, as it can only lead us to other undefined terms?" And why should one be puzzled just by the lack of a definition of time, and not by the lack of a definition of "chair"? Why shouldn't we be puzzled in all cases where we haven't got a definition? Now a definition often clears up the *grammar* of a word. And in fact it is the grammar of the word "time" which puzzles us. We are only expressing this puzzlement by asking a slightly misleading question, the question: "What is...?" This question is an utterance of unclarity, of mental discomfort, and it is comparable with the question "Why?" as children so often ask it. This too is an expression of a mental discomfort, and doesn't necessarily ask for either a cause or a reason. (Hertz, *Principles of Mechanics*.) Now the puzzlement about the grammar of the word "time" arises from what one might call apparent contradictions in that grammar.

Page 26

It was such a "contradiction" which puzzled Saint Augustine when he argued: How is it possible that one should measure time? For the past can't be measured, as it is gone by; and the future can't be measured because it

has not yet come. And the present can't be measured for it has no extension.

Page 26

The contradiction which here seems to arise could be called a conflict between two different usages of a word, in this case the word "measure". Augustine, we might say, thinks of the process of measuring a *length*: say, the distance between two marks on a travelling band which passes us, and of which we can only see a tiny bit (the present) in front of us. Solving this puzzle will consist in comparing what we mean by "measurement" (the grammar of the word "measurement") when applied to a distance on a travelling band with the grammar of that word when applied to time. The problem may seem simple, but its extreme difficulty is due to the fascination which the analogy between two similar structures in our language can exert on us. (It is helpful here to remember that it is sometimes almost impossible for a child to believe that one word can have two meanings.)

Page 26

Now it is clear that this problem about the concept of time asks for an answer given in the form of strict rules. The puzzle is about rules.--Take another example: Socrates' question "What is knowledge?"

Page Break 27

Here the case is even clearer, as the discussion begins with the pupil giving an example of an exact definition, and then analogous to this a definition of the word "knowledge" is asked for. As the problem is put, it seems that there is something wrong with the ordinary use of the word "knowledge". It appears we don't know what it means, and that therefore, perhaps, we have no right to use it. We should reply: "There is no one exact usage of the word 'knowledge'; but we can make up several such usages, which will more or less agree with the ways the word is actually used".

Page 27

The man who is philosophically puzzled sees a law in the way a word is used, and, trying to apply this law consistently, comes up against cases where it leads to paradoxical results. Very often the way the discussion of such a puzzle runs is this: First the question is asked "What is time?" This question makes it appear that what we want is a definition. We mistakenly think that a definition is what will remove the trouble (as in certain states of indigestion we feel a kind of hunger which cannot be removed by eating). The question is then answered by a wrong definition; say: "Time is the motion of the celestial bodies". The next step is to see that this definition is unsatisfactory. But this only means that we don't use the word "time" synonymously with "motion of the celestial bodies". However in saying that the first definition is wrong, we are now tempted to think that we must replace it by a different one, the correct one.

Page 27

Compare with this the case of the definition of number. Here the explanation that a number is the same thing as a numeral satisfies that first craving for a definition. And it is very difficult not to ask: "Well, if it isn't the numeral, *what is it?*"

Page 27

Philosophy, as we use the word, is a fight against the fascination which forms of expression exert upon us.

Page 27

I want you to remember that words have those meanings which we have given them; and we give them meanings by explanations. I may have given a definition of a word and used the word accordingly, or those who taught me the use of the word may have given me the explanation. Or else we might, by the explanation of a word, mean the explanation which, on being asked, we *are* ready to give. That is, if we are ready to give any explanation; in most cases we aren't. Many words in this sense then don't have a strict meaning. But this is not a defect. To think it is would be like saying that the light of my reading lamp is no real light at all because it has no sharp boundary.

Page 27

Philosophers very often talk about investigating, analysing, the

Page Break 28

meaning of words. But let's not forget that a word hasn't got a meaning given to it, as it were, by a power independent of us, so that there could be a kind of scientific investigation into what the word *really* means. A word has the meaning someone has given to it.

Page 28

There are words with several clearly defined meanings. It is easy to tabulate these meanings. And there are words of which one might say: They are used in a thousand different ways which gradually merge into one another. No wonder that we can't tabulate strict rules for their use.

Page 28

It is wrong to say that in philosophy we consider an ideal language as opposed to our ordinary one. For this

makes it appear as though we thought we could improve on ordinary language. But ordinary language is all right. Whenever we make up 'ideal languages' it is not in order to replace our ordinary language by them; but just to remove some trouble caused in someone's mind by thinking that he has got hold of the exact use of a common word. That is also why our method is not merely to enumerate actual usages of words, but rather deliberately to invent new ones, some of them because of their absurd appearance.

Page 28

When we say that by our method we try to counteract the misleading effect of certain analogies, it is important that you should understand that the idea of an analogy being misleading is nothing sharply defined. No sharp boundary can be drawn round the cases in which we should say that a man was misled by an analogy. The use of expressions constructed on analogical patterns stresses analogies between cases often far apart. And by doing this these expressions may be extremely useful. It is, in most cases, impossible to show an exact point where an analogy begins to mislead us. Every particular notation stresses some particular point of view. If, e.g., we call our investigations "philosophy", this title, on the one hand, seems appropriate, on the other hand it certainly has misled people. (One might say that the subject we are dealing with is one of the heirs of the subject which used to be called "philosophy".) The cases in which particularly we wish to say that someone is misled by a form of expression are those in which we would say: "he wouldn't talk as he does if he were aware of this difference in the grammar of such-and-such words, or if he were aware of this other possibility of expression" and so on. Thus we may say of some philosophizing mathematicians that they are obviously not aware of the difference between the many different usages of the word "proof"; and that they are not clear about

Page Break 29

the difference between the uses of the word "kind", when they talk of kinds of numbers, kinds of proofs, as though the word "kind" here meant the same thing as in the context "kinds of apples". Or, we may say, they are not aware of the different *meanings* of the word "discovery", when in one case we talk of the discovery of the construction of the pentagon and in the other case of the discovery of the South Pole.

Page 29

Now when we distinguished a transitive and an intransitive use of such words as "longing", "fearing", "expecting", etc., we said that some one might try to smooth over our difficulties by saying: "The difference between the two cases is simply that in one case we know what we are longing for and in the other we don't". Now who says this, I think, obviously doesn't see that the difference which he tried to explain away reappears when we carefully consider the use of the word "to know" in the two cases. The expression "the difference is simply..." makes it appear as though we had analysed the case and found a simple analysis; as when we point out that two substances with very different names hardly differ in composition.

Page 29

We said in this case that we might use both expressions: "we feel a longing" (where "longing" is used intransitively) and "we feel a longing and don't know what we are longing for". It may seem queer to say that we may correctly use either of two forms of expression which seem to contradict each other; but such cases are very frequent.

Page 29

Let us use the following example to clear this up. We say that the equation $x^2 = -1$ has the solution $\pm \sqrt{-1}$. There was a time when one said that this equation had no solution. Now this statement, whether agreeing or disagreeing, with the one which told us the solutions, certainly hasn't its multiplicity. But we can easily give it that multiplicity by saying that an equation $x^2 + ax + b = 0$ hasn't got a solution but comes α near to the nearest solution which is β . Analogously we can say either "A straight line always intersects a circle; sometimes in real, sometimes in complex points", or, "A straight line either intersects a circle, or it doesn't and is α far from doing so". These two statements mean exactly the same. They will be more or less satisfactory according to the way a man wishes to look at it. He may wish to make the difference between intersecting and not intersecting as inconspicuous as possible. Or on the other hand he may wish to stress it; and either tendency may be justified, say, by his particular practical purposes. But this may not be the reason at all why he prefers one form of expression to the other. Which form he

Page Break 30

prefers, and whether he has a preference at all, often depends on general, deeply rooted, tendencies of his thinking.

Page 30

(Should we say that there are cases when a man despises another man and doesn't know it; or should we describe such cases by saying that he doesn't despise him but unintentionally behaves towards him in a way--speaks to him in a tone of voice, etc.--which in general would go together with despising him? Either form of expression is

correct; but they may betray different tendencies of the mind.)

Page 30

Let us revert to examining the grammar of the expressions "to wish", "to expect", "to long for", etc., and consider that most important case in which the expression, "I wish so and so to happen" is the direct description of a conscious process. That is to say, the case in which we should be inclined to answer the question "Are you sure that it is this you wish?" by saying: "Surely I must know what I wish". Now compare this answer to the one which most of us would give to the question: "Do you know the ABC?" Has the emphatic assertion that you know it a sense analogous to that of the former assertion? Both assertions in a way brush aside the question. But the former doesn't wish to say "Surely I know such a simple thing as this" but rather: "The question which you asked me makes nonsense". We might say: We adopt in this case a wrong method of brushing aside the question. "Of course I know" could here be replaced by "Of course, there is no doubt" and this interpreted to mean "It makes, in this case, no sense of talk of a doubt". In this way the answer "Of course I know what I wish" can be interpreted to be a grammatical statement.

Page 30

It is similar when we ask, "Has this room a length?", and someone answers: "Of course it has". He might have answered, "Don't ask nonsense".. On the other hand "The room has length" can be used as a grammatical statement. It then says that a sentence of the form "The room is feet long" makes sense.

Page 30

A great many philosophical difficulties are connected with that sense of the expressions "to wish", "to think", etc., which we are now considering. These can all be summed up in the question: "How can one think what is not the case?"

Page 30

This is a beautiful example of a philosophical question. It asks "How can one...?" and while this puzzles us we must admit that nothing is easier than to think what is not the case. I mean, this shows us again that the difficulty which we are in does not arise through our inability to imagine how thinking something is done; just as the

Page Break 31

philosophical difficulty about the measurement of time did not arise through our inability to imagine how time was actually measured. I say this because sometimes it almost seems as though our difficulty were one of remembering exactly what happened when we thought something, a difficulty of introspection, or something of the sort; whereas in fact it arises when we look at the facts through the medium of a misleading form of expression.

Page 31

"How can one think what is not the case? If I think that King's College is on fire when it is not on fire, the fact of its being on fire does not exist. Then how can I think it? How can we hang a thief who doesn't exist?" Our answer could be put in this form: "I can't hang him when he doesn't exist; but I can look for him when he doesn't exist".

Page 31

We are here misled by the substantives "object of thought" and "fact", and by the different meanings of the word "exist".

Page 31

Talking of the fact as a "complex of objects" springs from this confusion (cf. *Tractatus Logico-philosophicus*). Supposing we asked: "How can one *imagine* what does not exist?" The answer seems to be: "If we do, we imagine non-existent combinations of existing elements". A centaur doesn't exist, but a man's head and torso and arms and a horse's legs do exist. "But can't we imagine an object utterly different from any one which exists?"--We should be inclined to answer: "No; the elements, individuals, must exist. If redness, roundness and sweetness did not exist, we could not imagine them".

Page 31

But what do you mean by "redness exists"? My watch exists, if it hasn't been pulled to pieces, if it hasn't been *destroyed*. What would we call "destroying redness"? We might of course mean destroying all red objects; but would this make it impossible to imagine a red object? Supposing to this one answered: "But surely, red objects must have existed and you must have seen them if you are able to imagine them"?--But how do you know that this is so? Suppose I said "Exerting a pressure on your eye-ball produces a red image". Couldn't the way by which you first became acquainted with red have been this? And why shouldn't it have been just imagining a red patch? (The difficulty which you may feel here will have to be discussed at a later occasion. †1)

Page 31

We may now be inclined to say: "As the *fact* which would make our thought true if it existed does not always exist, it is not the fact which we think". But this just depends upon how I wish to use the word

Page Break 32

"fact". Why shouldn't I say: "I believe the fact that the college is on fire"? It is just a clumsy expression for saying: "I believe that the college is on fire". To say "It is not the fact which we believe", is itself the result of a confusion. We think we are saying something like: "It isn't the sugar-cane which we eat but the sugar", "It isn't Mr. Smith who hangs in the gallery, but his picture".

Page 32

The next step we are inclined to take is to think that as the object of our thought isn't the fact it is a shadow of the fact. There are different names for this shadow, e.g. "proposition", "sense of the sentence".

Page 32

But this doesn't remove our difficulty. For the question now is: "How can something be the shadow of a fact which doesn't exist?"

Page 32

I can express our trouble in a different form by saying: "How can we know what the shadow is a shadow of?"--The shadow would be some sort of portrait; and therefore I can restate our problem by asking: "What makes a portrait a portrait of Mr. N?" The answer which might first suggest itself is: "The similarity between the portrait and Mr. N". This answer in fact shows what we had in mind when we talked of the shadow of a fact. It is quite clear, however, that similarity does not constitute our idea of a portrait; for it is in the essence of this idea that it should make sense to talk of a good or a bad portrait. In other words, it is essential that the shadow should be capable of representing things as in fact they are not.

Page 32

An obvious, and correct, answer to the question "What makes a portrait the portrait of so-and-so?" is that it is the *intention*. But if we wish to know what it means "intending this to be a portrait of so-and-so" let's see what actually happens when we intend this. Remember the occasion when we talked of what happened when we expect some one from four to four-thirty. To intend a picture to be the portrait of so-and-so (on the part of the painter, e.g.) is neither a particular state of mind nor a particular mental process. But there are a great many combinations of actions and states of mind which we should call "intending..." It might have been that he was told to paint a portrait of N, and sat down before N, going through certain actions which we call "copying N's face". One might object to this by saying that the essence of copying is the intention to copy. I should answer that there are a great many different processes which we call "copying something". Take an instance. I draw an ellipse on a sheet of paper and ask you to copy it. What characterizes the process of copying? For it is clear that it isn't the fact that you draw a similar

Page Break 33

ellipse. You might have tried to copy it and not succeeded; or you might have drawn an ellipse with a totally different intention, and it happened to be like the one you should have copied. So what do you do when you try to copy the ellipse? Well, you look at it, draw something on a piece of paper, perhaps measure what you have drawn, perhaps you curse if you find it doesn't agree with the model; or perhaps you say "I am going to copy this ellipse" and just draw an ellipse like it. There are an endless variety of actions and words, having a family likeness to each other, which we call "trying to copy".

Page 33

Suppose we said "that a picture is a portrait of a particular object consists in its being derived from that object in a particular way". Now it is easy to describe what we should call processes of deriving a picture from an object (roughly speaking, processes of projection). But there is a peculiar difficulty about admitting that any such process is what we call "intentional representation". For describe whatever process (activity) of projection we may, there is a way of reinterpreting this projection. Therefore--one is tempted to say--such a process can never be the intention itself. For we could always have intended the opposite by reinterpreting the process of projection. Imagine this case: We give someone an order to walk in a certain direction by pointing or by drawing an arrow which points in the direction. Suppose drawing arrows is the language in which generally we give such an order. Couldn't such an order be interpreted to mean that the man who gets it is to walk in the direction opposite to that of the arrow? This could obviously be done by adding to our arrow some symbols which we might call "an *interpretation*". It is easy to imagine a case in which, say to deceive someone, we might make an arrangement that an order should be carried out in the sense opposite to its normal one. The symbol which adds the interpretation to our original arrow could, for instance, be another arrow. Whenever we interpret a symbol in one way or another, the interpretation is a new symbol added to the old one.

Page 33

Now we might say that whenever we give someone an order by showing him an arrow, and don't do it 'mechanically' (without thinking), we *mean* the arrow in one way or another. And this process of meaning, of whatever kind it may be, can be represented by another arrow (pointing in the same or the opposite sense to the first). In this picture which we make of 'meaning and saying' it is essential that we should imagine the processes of saying and meaning to take place in two different spheres.

Page Break 34

Page 34

Is it then correct to say that no arrow could be the meaning, as every arrow could be meant the opposite way?--Suppose we write down the scheme of saying and meaning by a column of arrows one below the other.

Then if this scheme is to serve our purpose at all, it must show us which of the three levels is the level of meaning. I can, e.g., make a scheme with three levels, the bottom level always being the level of meaning. But adopt whatever model or scheme you may, it will have a bottom level, and there will be no such thing as an interpretation of that. To say in this case that every arrow can still be interpreted would only mean that I *could* always make a different model of saying and meaning which had one more level than the one I am using.

Page 34

Let us put it in this way:--What one wishes to say is: "Every sign is capable of interpretation; but the *meaning* mustn't be capable of interpretation. It is the last interpretation." Now I assume that you take the meaning to be a process accompanying the saying, and that it is translatable into, and so far equivalent to, a further sign. You have therefore further to tell me what you take to be the distinguishing mark between *a sign* and *the meaning*. If you do so, e.g., by saying that the meaning is the arrow which you *imagine* as opposed to any which you may draw or produce in any other way, you thereby say that you will call no further arrow an interpretation of the one which you have imagined.

Page 34

All this will become clearer if we consider what it is that really happens when we say a thing and mean what we say.--Let us ask ourselves: If we say to someone "I should be delighted to see you" and mean it, does a conscious process run alongside these words, a process which could itself be translated into spoken words? This will hardly ever be the case.

Page 34

But let us imagine an instance in which it does happen. Supposing I had a habit of accompanying every English sentence which I said aloud by a German sentence spoken to myself inwardly. If then, for some reason or other, you call the silent sentence the meaning of the one spoken aloud, the process of meaning accompanying the process of saying would be one which could itself be translated into outward signs. Or, *before* any sentence which we say aloud we say its meaning

Page Break 35

(whatever it may be) to ourselves in a kind of aside. An example at least similar to the case we want would be saying one thing and at the same time seeing a picture before our mind's eye which is the meaning and agrees or disagrees with what we say. Such cases and similar ones exist, but they are not at all what happens as a rule when we say something and mean it, or mean something else. There are, of course, real cases in which what we call meaning is a definite conscious process accompanying, preceding, or following the verbal expression and itself a verbal expression of some sort or translatable into one. A typical example of this is the 'aside' on the stage.

Page 35

But what tempts us to think of the meaning of what we say as a process essentially of the kind which we have described is the analogy between the forms of expression:

"to say something"
"to mean something",

which seem to refer to two parallel processes.

Page 35

A process accompanying our words which one might call the "process of meaning them" is the modulation

of the voice in which we speak the words; or one of the processes similar to this, like the play of facial expression. These accompany the spoken words not in the way a German sentence might accompany an English sentence, or writing a sentence accompany speaking a sentence; but in the sense in which the tune of a song accompanies its words. This tune corresponds to the 'feeling' with which we say the sentence. And I wish to point out that this feeling is the expression with which the sentence is said, or something similar to this expression.

Page 35

Let us revert to our question: "What is the object of a thought?" (e.g. when we say, "I think that King's College is on fire").

Page 35

The question as we put it is already the expression of several confusions. This is shown by the mere fact that it almost sounds like a question of physics; like asking: "What are the ultimate constituents of matter?" (It is a typically metaphysical question; the characteristic of a metaphysical question being that we express an unclarity about the grammar of words in the *form* of a scientific question.)

Page 35

One of the origins of our question is the two-fold use of the propositional function "I think x ". We say, "I think that so-and-so will happen" or "that so-and-so is the case", and also "I think just the same *thing* as he"; and we say "I expect him", and also "I expect that he will come". Compare "I expect him" and "I shoot him". We can't

Page Break 36

shoot him if he isn't there. This is how the question arises: "How can we expect something that is not the case?", "How can we expect a fact which does not exist?"

Page 36

The way out of this difficulty seems to be: what we expect is not the fact, but a shadow of the fact; as it were, the next thing to the fact. We have said that this is only pushing the question one step further back. There are several origins to this idea of a shadow. One of them is this: we say "Surely two sentences of different languages can have the same sense"; and we argue, "therefore the sense is not the same as the sentence", and ask the question "What is the sense?" And we make of 'it' a shadowy being, one of the many which we create when we wish to give meaning to substantives to which no material objects correspond.

Page 36

Another source of the idea of a shadow being the object of our thought is this: We imagine the shadow to be a picture the intention of which *cannot be questioned*, that is, a picture which we don't interpret in order to understand it, but which we understand without interpreting it. Now there are pictures of which we should say that we interpret them, that is, translate them into a different kind of picture, in order to understand them; and pictures of which we should say that we understand them immediately, without any further interpretation. If you see a telegram written in cipher, and you know the key to this cipher, you will, in general, not say that you understand the telegram before you have translated it into ordinary language. Of course you have only replaced one kind of symbols by another; and yet if now you read the telegram in your language no further process of interpretation will take place.--Or rather, you may now, in certain cases, again translate this telegram, say into a picture; but then too you have only replaced one set of symbols by another.

Page 36

The shadow, as we think of it, is some sort of a picture; in fact, something very much like an image which comes before our mind's eye; and this again is something not unlike a painted representation in the ordinary sense. A source of the idea of the shadow certainly is the fact that in some cases saying, hearing, or reading a sentence brings images before our mind's eye, images which more or less strictly correspond to the sentence, and which are therefore, in a sense, translations of this sentence into a pictorial language.--But it is absolutely essential for the picture which we imagine the shadow to be that it is what I shall call a "picture by similarity". I don't mean by this that it is a picture similar to what it is intended to

Page Break 37

represent, but that it is a picture which is correct only when it is similar to what it represents. One might use for this kind of picture the word "copy". Roughly speaking, copies are good pictures when they can easily be mistaken for what they represent.

Page 37

A plane projection of one hemisphere of our terrestrial globe is not a picture by similarity or a copy in this sense. It would be conceivable that I portrayed some one's face by projecting it in some queer way, though correctly according to the adopted rule of projection, on a piece of paper, in such a way that no one would normally call the projection "a good portrait of so-and-so" because it would not look a bit like him.

If we keep in mind the possibility of a picture which, though correct, has no similarity with its object, the interpolation of a shadow between the sentence and reality loses all point. For now the sentence itself can serve as such a shadow. The sentence is just such a picture, which hasn't the slightest similarity with what it represents. If we were doubtful about how the sentence "King's College is on fire" can be a picture of King's College on fire, we need only ask ourselves: "How should we explain what the sentence means?" Such an explanation might consist of ostensive definitions. We should say, e.g., "this is King's College" (pointing to the building), "this is a fire" (pointing to a fire). This shews you the way in which words and things may be connected.

The idea that that which we wish to happen must be present as a shadow in our wish is deeply rooted in our forms of expression. But, in fact, we might say that it is only the next best absurdity to the one which we should really like to say. If it weren't too absurd we should say that the fact which we wish for must be present in our wish. For how can we wish *just this* to happen if just this isn't present in our wish? It is quite true to say: The mere shadow won't do; for it stops short before the object; and we want the wish to contain the object itself.--We want that the wish that Mr. Smith should come into this room should wish that just *Mr. Smith*, and no substitute, should do the *coming*, and no substitute for that, *into my room*, and no substitute for that. But this is exactly what we said.

Our confusion could be described in this way: Quite in accordance with our usual form of expression we think of the fact which we wish for as a thing which is not yet here, and to which, therefore, we cannot point. Now in order to understand the grammar of our expression "object of our wish" let's just consider the answer which we give

to the question: "What is the object of your wish?" The answer to this question of course is "I wish that so-and-so should happen". Now what would the answer be if we went on asking: "And what is the object of this wish?" It could only consist in a repetition of our previous expression of the wish, or else in a translation into some other form of expression. We might, e.g., state what we wished in other words or illustrate it by a picture, etc., etc. Now when we are under the impression that what we call the object of our wish is, as it were, a man who has not yet entered our room, and therefore can't yet be seen, we imagine that any explanation of what it is we wish is only the next best thing to the explanation which would show *the actual fact*--which, we are afraid, can't yet be shown as it has not yet entered.--It is as though I said to some one "I am expecting Mr. Smith", and he asked me "Who is Mr. Smith?", and I answered, "I can't show him to you now, as he isn't there. All I can show you is a picture of him". It then seems as though I could never entirely explain what I wished until it had actually happened. But of course this is a delusion. The truth is that I needn't be able to give a better explanation of what I wished after the wish was fulfilled than before; for I might perfectly well have shown Mr. Smith to my friend, and have shown him what "coming in" means, and have shown him what my room is, before Mr. Smith came into my room.

Our difficulty could be put this way: We think about things,--but how do these things enter into our thoughts? We think about Mr. Smith; but Mr. Smith need not be present. A picture of him won't do; for how are we to know whom it represents? In fact no substitute for hint will do. Then how can he himself be an object of our thoughts? (I am here using the expression "object of our thought" in a way different from that in which I have used it before. I mean now a thing I am thinking *about*, not 'that which I am thinking'.)

We said the connection between our thinking, or speaking, about a man and the man himself was made when, in order to explain the meaning of the word "Mr. Smith" we pointed to him, saying "this is Mr. Smith". And there is nothing mysterious about this connection. I mean, there is no queer mental act which somehow conjures up Mr. Smith in our minds when he really isn't here. What makes it difficult to see that this is the connection is a peculiar form of expression of ordinary language, which makes it appear that the connection between our thought (or the expression of our thought) and the thing we think about must have subsisted *during* the act of thinking.

"Isn't it queer that in Europe we should be able to mean someone who is in America?"--If someone had said "Napoleon was crowned in 1804", and we asked him "Did you mean the man who won the battle of Austerlitz?" he might say "Yes, I meant him". And the use of the past tense "meant" might make it appear as though the idea of Napoleon having won the battle of Austerlitz must have been present in the man's mind when he said that Napoleon was crowned in 1804.

Someone says, "Mr. N. will come to see me this afternoon"; I ask "Do you mean him?" pointing to someone present, and he answers "Yes". In this conversation a connection was established between the word "Mr. N." and Mr. N. But we are tempted to think that while my friend said, "Mr. N. will come to see me", and meant what he said, his mind must have made the connection.

Page 39

This is partly what makes us think of meaning or thinking as a peculiar *mental activity*; the word "mental" indicating that we mustn't expect to understand how these things work.

Page 39

What we said of thinking can also be applied to imagining. Someone says, he imagines King's College on fire. We ask him: "How do you know that it's *King's College* you imagine on fire? Couldn't it be a different building, very much like it? In fact, is your imagination so absolutely exact that there might not be a dozen buildings whose representation your image could be?"--And still you say: "There's no doubt I imagine King's College and no other building". But can't saying this be making the very connection we want? For saying it is like writing the words "Portrait of Mr. So-and-so" under a picture. It might have been that *while* you imagined King's College on fire you said the words "King's College is on fire". But in very many cases you certainly don't speak explanatory words in your mind while you have the image. And consider, even if you do, you are not going the whole way from your image to King's College, but only to the words "King's College". The connection between these words and King's College was, perhaps, made at another time.

Page 39

The fault which in all our reasoning about these matters we are inclined to make is to think that images and experiences of all sorts, which are in some sense closely connected with each other, must be present in our mind at the same time. If we sing a tune we know by heart, or say the alphabet, the notes or letters seem to hang together, and each seems to draw the next after it, as though they were a string of

Page Break 40

pearls in a box, and by pulling out one pearl I pulled out the one following it.

Page 40

Now there is no doubt that, having the visual image of a string of beads being pulled out of a box through a hole in the lid, we should be inclined to say: "These beads must all have been together in the box before". But it is easy to see that this is making a hypothesis. I should have had the same image if the beads had gradually come into existence in the hole of the lid. We easily overlook the distinction between stating a conscious mental event, and making a hypothesis about what one might call the mechanism of the mind. All the more as such hypotheses or pictures of the working of our mind are embodied in many of the forms of expression of our everyday language. The past tense "meant" in the sentence "I meant the man who won the battle of Austerlitz" is part of such a picture, the mind being conceived as a place in which what we remember is kept, stored, before we express it. If I whistle a tune I know well and am interrupted in the middle, if then someone asks me "did you know how to go on?" I should answer "yes, I did". What sort of process is this *knowing how to go on*? It might appear as though the whole continuation of the tune had to be present while I knew how to go on.

Page 40

Ask yourself such a question as: "How long does it take to know how to go on?" Or is it an instantaneous process? Aren't we making a mistake like mixing up the existence of a gramophone record of a tune with the existence of the tune? And aren't we assuming that whenever a tune passes through existence there must be some sort of a gramophone record of it from which it is played?

Page 40

Consider the following example: A gun is fired in my presence and I say: "This crash wasn't as loud as I had expected". Someone asks me: "How is this possible? Was there a crash, louder than that of a gun, in your imagination?" I must confess that there was nothing of the sort. Now he says: "Then you didn't really expect a louder crash-but perhaps the shadow of one.--And how did you know that it was the shadow of a louder crash?"--Let's see what, in such a case, might really have happened. Perhaps in waiting for the report I opened my mouth, held on to something to steady myself, and perhaps I said: "This is going to be terrible". Then, when the explosion was over: "It wasn't so loud after all".--Certain tensions in my body relax. But what is the connection between these tensions, opening my mouth, etc., and a real louder crash? Perhaps this connection

Page Break 41

was made by having heard such a crash and having had the experiences mentioned.

Page 41

Examine expressions like "having an idea in one's mind", "analysing the idea before one's mind". In order not

to be misled by them see what really happens when, say, in writing a letter you are looking for the words which correctly express the idea which is "before your mind". To say that we are trying to express the idea which is before our mind is to use a metaphor, one which very naturally suggests itself; and which is all right so long as it doesn't mislead us when we are philosophizing. For when we recall what really happens in such cases we find a great variety of processes more or less akin to each other.--We might be inclined to say that in all such cases, at any rate, we are *guided* by something before our mind. But then the words "guided" and "thing before our mind" are used in as many senses as the words "idea" and "expression of an idea".

Page 41

The phrase "to express an idea which is before our mind" suggests that what we are trying to express in words is already expressed, only in a different language; that this expression is before our mind's eye; and that what we do is to translate from the mental into the verbal language. In most cases which we call "expressing an idea, etc." something very different happens. Imagine what it is that happens in cases such as this: I am groping for a word. Several words are suggested and I reject them. Finally one is proposed and I say: "That is what I meant!"

Page 41

(We should be inclined to say that the proof of the impossibility of trisecting the angle with ruler and compasses analyses our idea of the trisection of an angle. But the proof gives us a new idea of trisection, one which we didn't have before the proof constructed it. The proof led us a road *which we were inclined to go*; but it led us away from where we were, and didn't just show us clearly the place where we had been all the time.)

Page 41

Let us now revert to the point where we said that we gained nothing by assuming that a shadow must intervene between the expression of our thought and the reality with which our thought is concerned. We said that if we wanted a picture of reality the sentence itself *is* such a picture (though not a picture by similarity).

Page 41

I have been trying in all this to remove the temptation to think that there '*must* be' what is called a mental process of thinking, hoping, wishing, believing, etc., independent of the process of expressing a thought, a hope, a wish, etc. And I want to give you the following

Page Break 42

rule of thumb: If you are puzzled about the nature of thought, belief, knowledge, and the like, substitute for the thought the expression of the thought, etc. The difficulty which lies in this substitution, and at the same time the whole point of it, is this: the expression of belief, thought, etc., is just a sentence;--and the sentence has sense only as a member of a system of language; as one expression within a calculus. Now we are tempted to imagine this calculus, as it were, as a permanent background to every sentence which we say, and to think that, although the sentence as written on a piece of paper or spoken stands isolated, in the mental act of thinking the calculus is there--all in a lump. The mental act seems to perform in a miraculous way what could not be performed by any act of manipulating symbols. Now when the temptation to think that in some sense the whole calculus must be present at the same time vanishes, there is no more point in *postulating* the existence of a peculiar kind of mental act alongside of our expression. This, of course, doesn't mean that we have shown that peculiar acts of consciousness do not accompany the expressions of our thoughts! Only we no longer say that they *must* accompany them.

Page 42

"But the expression of our thoughts can always lie, for we may say one thing and mean another". Imagine the many different things which happen when we say one thing and mean another!--Make the following experiment: say the sentence "It is hot in this room", and mean: "it is cold". Observe closely what you are doing.

Page 42

We could easily imagine beings who do their private thinking by means of 'asides' and who manage their lies by saying one thing aloud, following it up by an aside which says the opposite.

Page 42

"But meaning, thinking, etc., are private experiences. They are not activities like writing, speaking, etc."--But why shouldn't they be the specific private experiences of writing--the muscular, visual, tactile sensations of writing or speaking?

Page 42

Make the following experiment: say and mean a sentence, e.g.: "It will probably rain tomorrow". Now think the same thought again, mean what you just meant, but without saying anything (either aloud or to yourself). If thinking that it will rain tomorrow accompanied saying that it will rain tomorrow, then just do the first activity and leave out the second.--If thinking and speaking stood in the relation of the words and the melody of a song, we could leave out the speaking and do the thinking just as we can sing the tune without the words.

But can't one at any rate speak and leave out the thinking? Certainly--but observe what sort of thing you are doing if you speak without thinking. Observe first of all that the process which we might call "speaking and meaning what you speak" is not necessarily distinguished from that of speaking thoughtlessly by what happens *at the time when you speak*. What distinguishes the two may very well be what happens before or after you speak.

Suppose I tried, deliberately, to speak without thinking;--what in fact would I do? I might read out a sentence from a book, trying to read it automatically, that is, trying to prevent myself from following the sentence with images and sensations which otherwise it would produce. A way of doing this would be to concentrate my attention on something else while I was speaking the sentence, e.g., by pinching my skin hard while I was speaking.--Put it this way: Speaking a sentence without thinking consists in switching on speech and switching off certain accompaniments of speech. Now ask yourself: Does thinking the sentence without speaking it consist in turning over the switch (switching on what we previously switched off and vice versa); that is: does thinking the sentence without speaking it now simply consist in keeping on what accompanied the words but leaving out the words? Try to think the thoughts of a sentence without the sentence and see whether this is what happens.

Let us sum up: If we scrutinize the usages which we make of such words as "thinking", "meaning", "wishing", etc., going through this process rids us of the temptation to look for a peculiar act of thinking, independent of the act of expressing our thoughts, and stowed away in some peculiar medium. We are no longer prevented by the established forms of expression from recognizing that the experience of thinking *may* be just the experience of saying, or may consist of this experience plus others which accompany it. (It is useful also to examine the following case: Suppose a multiplication is part of a sentence; ask yourself what it is like to say the multiplication $7 \times 5 = 35$, thinking it, and, on the other hand, saying it without thinking.) The scrutiny of the grammar of a word weakens the position of certain fixed standards of our expression which had prevented us from seeing facts with unbiassed eyes. Our investigation tried to remove this bias, which forces us to think that the facts *must* conform to certain pictures embedded in our language.

"Meaning" is one of the words of which one may say that they have odd jobs in our language. It is these words which cause most

philosophical troubles. Imagine some institution: most of its members have certain regular functions, functions which can easily be described, say, in the statutes of the institution. There are, on the other hand, some members who are employed for odd jobs, which nevertheless may be extremely important.--What causes most trouble in philosophy is that we are tempted to describe the use of important 'odd-job' words as though they were words with regular functions.

The reason I postponed talking about personal experience was that thinking about this topic raises a host of philosophical difficulties which threaten to break up all our commonsense notions about what we should commonly call the objects of our experience. And if we were struck by these problems it might seem to us that all we have said about signs and about the various objects we mentioned in our examples may have to go into the melting-pot.

The situation in a way is typical in the study of philosophy; and one sometimes has described it by saying that no philosophical problem can be solved until all philosophical problems are solved; which means that as long as they aren't all solved every new difficulty renders all our previous results questionable. To this statement we can only give a rough answer if we are to speak about philosophy in such general terms. It is, that every new problem which arises may put in question the *position* which our previous partial results are to occupy in the final picture. One then speaks of having to reinterpret these previous results; and we should say: they have to be placed in a different surrounding.

Imagine we had to arrange the books of a library. When we begin the books lie higgledy-piggledy on the floor. Now there would be many ways of sorting them and putting them in their places. One would be to take the books one by one and put each on the shelf in its right place. On the other hand we might take up several books from the floor and put them in a row on a shelf, merely in order to indicate that these books ought to go together in this order. In the course of arranging the library this whole row of books will have to change its place. But it would be wrong to say that therefore putting them together on a shelf was no step towards the final result. In this case, in

fact, it is pretty obvious that having put together books which belong together was a definite achievement, even though the whole row of them had to be shifted. But some of the greatest achievements in philosophy could only be compared with taking up some books which seemed to belong together, and putting them on different

Page Break 45

shelves; nothing more being final about their positions than that they no longer lie side by side. The onlooker who doesn't know the difficulty of the task might well think in such a case that nothing at all had been achieved.--The difficulty in philosophy is to say no more than we know. E.g., to see that when we have put two books together in their right order we have not thereby put them in their final places.

Page 45

When we think about the relation of the objects surrounding us to our personal experiences of them, we are sometimes tempted to say that these personal experiences are the material of which reality consists. How this temptation arises will become clearer later on.

Page 45

When we think in this way we seem to lose our firm hold on the objects surrounding us. And instead we are left with a lot of separate personal experiences of different individuals. These personal experiences again seem vague and seem to be in constant flux. Our language seems not to have been made to describe them. We are tempted to think that in order to clear up such matters philosophically our ordinary language is too coarse, that we need a more subtle one.

Page 45

We seem to have made a discovery--which I could describe by saying that the ground on which we stood and which appeared to be firm and reliable was found to be boggy and unsafe.--That is, this happens when we philosophize; for as soon as we revert to the standpoint of common sense this *general* uncertainty disappears.

Page 45

This queer situation can be cleared up somewhat by looking at an example; in fact a kind of parable illustrating the difficulty we are in, and also showing the way out of this sort of difficulty: We have been told by popular scientists that the floor on which we stand is not solid, as it appears to common sense, as it has been discovered that the wood consists of particles filling space so thinly that it can almost be called empty. This is liable to perplex us, for in a way of course we know that the floor is solid, or that, if it isn't solid, this may be due to the wood being rotten but not to its being composed of electrons. To say, on this latter ground, that the floor is not solid is to misuse language. For even if the particles were as big as grains of sand, and as close together as these are in a sandheap, the floor would not be solid if it were composed of them in the sense in which a sandheap is composed of grains. Our perplexity was based on a misunderstanding; the picture of the thinly filled space had been wrongly *applied*. For this picture of the structure of matter was meant to explain the very phenomenon of solidity.

Page 45

As in this example the word "solidity" was used wrongly and it

Page Break 46

seemed that we had shown that nothing really was solid, just in this way, in stating our puzzles about the *general vagueness* of sense-experience, and about the flux of all phenomena, we are using the words "flux" and "vagueness" wrongly, in a typically metaphysical way, namely without an antithesis; whereas in their correct and everyday use vagueness is opposed to clearness, flux to stability, inaccuracy to accuracy, and *problem* to *solution*. The very word "problem", one might say, is misapplied when used for our philosophical troubles. These difficulties, as long as they are seen as problems, are tantalizing, and appear insoluble.

Page 46

There is a temptation for me to say that only my own experience is real: "I know that I see, hear, feel pains, etc., but not that anyone else does. I can't know this, because I am I and they are they."

Page 46

On the other hand I feel ashamed to say to anyone that my experience is the only real one; and I know that he will reply that he could say exactly the same thing about his experience. This seems to lead to a silly quibble. Also I am told: "If you pity someone for having pains, surely you must at least *believe* that he has pains". But how can I even *believe* this? How can these words make sense to me? How could I even have come by the idea of another's experience if there is no possibility of any evidence for it?

Page 46

But wasn't this a queer question to ask? *Can't* I believe that someone else has pains? Is it not quite easy to believe this?--Is it an answer to say that things are as they appear to common sense?--Again, needless to say, we don't feel these difficulties in ordinary life. Nor is it true to say that we feel them when we scrutinize our experiences

by introspection, or make scientific investigations about them. But somehow, when we look at them in a certain way, our expression is liable to get into a tangle. It seems to us as though we had either the wrong pieces, or not enough of them, to put together our jigsaw puzzle. But they *are* all there, only all mixed up; and there is a further analogy between the jig-saw puzzle and our case: It's no use trying to apply force in fitting pieces together. All we should do is to look at them *carefully* and arrange them.

Page 46

There are propositions of which we may say that they describe facts in the material world (external world). Roughly speaking, they treat of physical objects: bodies, fluids, etc. I am not thinking in particular of the laws of the natural sciences, but of any such proposition as "the tulips in our garden are in full bloom", or "Smith will come in any moment". There are on the other hand propositions

Page Break 47

describing personal experiences, as when the subject in a psychological experiment describes his sense-experiences; say his visual experience, independent of what bodies are actually before his eyes and, *n.b.*, independent also of any processes which might be observed to take place in his retina, his nerves, his brain, or other parts of his body. (That is, independent of both physical and physiological facts.)

Page 47

At first sight it may appear (but why it should can only become clear later) that here we have two kinds of worlds, worlds built of different materials; a mental world and a physical world. The mental world in fact is liable to be imagined as gaseous, or rather, aethereal. But let me remind you here of the queer role which the gaseous and the aethereal play in philosophy,--when we perceive that a substantive is not used as what in general we should call the name of an object, and when therefore we can't help saying to ourselves that it is the name of an aethereal object. I mean, we already know the idea of 'aethereal objects' as a subterfuge, when we are embarrassed about the grammar of certain words, and when all we know is that they are not used as names for material objects. This is a hint as to how the problem of the two materials, *mind* and *matter*, is going to dissolve.

Page 47

It seems to us sometimes as though the phenomena of personal experience were in a way phenomena in the upper strata of the atmosphere as opposed to the material phenomena which happen on the ground. There are views according to which these phenomena in the upper strata arise when the material phenomena reach a certain degree of complexity. E.g., that the mental phenomena, sense experience, volition, etc., emerge when a type of animal body of a certain complexity has been evolved. There seems to be some obvious truth in this, for the amoeba certainly doesn't speak or write or discuss, whereas we do. On the other hand the problem here arises which could be expressed by the question: "Is it possible for a machine to think?" (whether the action of this machine can be described and predicted by the laws of physics or, possibly, only by laws of a different kind applying to the behaviour of organisms). And the trouble which is expressed in this question is not really that we don't yet know a machine which could do the job. The question is not analogous to that which someone might have asked a hundred years ago: "Can a machine liquefy a gas?" The trouble is rather that the sentence, "A machine thinks (perceives, wishes)": seems somehow nonsensical. It is as though we had asked "Has the number 3 a colour?" ("What colour could it be, as it obviously has none of the colours known to

Page Break 48

us?") For in one aspect of the matter, personal experience, far from being the *product* of physical, chemical, physiological processes, seems to be the very *basis* of all that we say with any sense about such processes. Looking at it in this way we are inclined to use our idea of a building-material in yet another misleading way, and to say that the whole world, mental and physical, is made of one material only.

Page 48

When we look at everything that we know and can say about the world as resting upon personal experience, then what we know seems to lose a good deal of its value, reliability, and solidity. We are then inclined to say that it is all "subjective"; and "subjective" is used derogatorily, as when we say that an opinion is *merely* subjective, a matter of taste. Now, that this aspect should seem to shake the authority of experience and knowledge points to the fact that here our language is tempting us to draw some misleading analogy. This should remind us of the case when the popular scientist appeared to have shown us that the floor which we stand on is not really solid because it is made up of electrons.

Page 48

We are up against trouble caused by our way of expression.

Page 48

Another such trouble, closely akin, is expressed in the sentence: "I can only know that I have personal

experiences, not that anyone else has".--Shall we then call it an unnecessary hypothesis that anyone else has personal experiences?--But is it an hypothesis at all? For how can I even make the hypothesis if it transcends all possible experience? How could such a hypothesis be backed by meaning? (Is it not like paper money, not backed by gold?)--It doesn't help if anyone tells us that, though we don't know whether the other person has pains, we certainly believe it when, for instance, we pity him. Certainly we shouldn't pity him if we didn't believe that he had pains; but is this a philosophical, a metaphysical belief? Does a realist pity me more than an idealist or a solipsist?--In fact the solipsist asks: "How *can* we believe that the other has pain; what does it mean to believe this? How can the expression of such a supposition make sense?"

Page 48

Now the answer of the common-sense philosopher--and that, *n.b.*, is not the commonsense man, who is as far from realism as from idealism--the answer of the common-sense philosopher is that surely there is no difficulty in the idea of supposing, thinking, imagining that someone else has what I have. But the trouble with the realist is always that he does not solve but skip the difficulties which his adversaries see, though they too don't succeed in solving them. The

Page Break 49

realist answer, for us, just brings out the difficulty; for who argues like this overlooks the difference between different usages of the words "to have", "to imagine". "A has a gold tooth" means that the tooth is in A's mouth. This may account for the fact that I am not able to see it. Now the case of his toothache, of which I say that I am not able to feel it because it is in his mouth, is not analogous to the case of the gold tooth. It is the apparent analogy, and again the lack of analogy, between these cases which causes our trouble. And it is this troublesome feature in our grammar which the realist does not notice. It is conceivable that I feel pain in a tooth in another man's mouth; and the man who says that he cannot feel the other's toothache is not denying *this*. The grammatical difficulty which we are in we shall only see clearly if we get familiar with the idea of feeling pain in another person's body. For otherwise, in puzzling about this problem, we shall be liable to confuse our metaphysical proposition "I can't feel his pain" with the experiential proposition, "We can't have (haven't as a rule) pains in another person's tooth". In this proposition the word "can't" is used in the same way as in the proposition "An iron nail can't scratch glass". (We could write this in the form "experience teaches that an iron nail *doesn't* scratch glass", thus doing away with the "can't".) In order to see that it is conceivable that one person should have pain in another person's body, one must examine what sort of facts we call criteria for a pain being in a certain place. It is easy to imagine the following case: When I see my hands I am not always aware of their connection with the rest of my body. That is to say, I often see my hand moving but don't see the arm which connects it to my torso. Nor do I necessarily, at the time, check up on the arm's existence in any other way. Therefore the hand may, for all I know, be connected to the body of a man standing beside me (or, of course, not to a human body at all). Suppose I feel a pain which on the evidence of the pain alone, e.g., with closed eyes, I should call a pain in my left hand. Someone asks me to touch the painful spot with my right hand. I do so and looking round perceive that I am touching my neighbour's hand (meaning the hand connected to my neighbour's torso).

Page 49

Ask yourself: How do we know where to point to when we are asked to point to the painful spot? Can this sort of pointing be compared with pointing to a black spot on a sheet of paper when someone says: "Point to the black spot on this sheet"? Suppose someone said "You point to this spot because you know before you point that the

Page Break 50

pains are there"; ask yourself "What does it mean to *know* that the pains are there?" The word "there" refers to a locality;--but in what space, i.e., a 'locality' in what sense? Do we know the place of pain in Euclidean space, so that when we know where we have pains we know how far away from two of the walls of this room, and from the floor? When I have pain in the tip of my finger and touch my tooth with it, is my pain now both a toothache and a pain in my finger? Certainly, in one sense the pain can be said to be located on the tooth. Is the reason why in this case it is wrong to say I have toothache, that in order to be in the tooth the pain should be one sixteenth of an inch away from the tip of my finger? Remember that the word "where" can refer to localities in many different senses. (Many different grammatical games, resembling each other *more* or *less*, are played with this word. Think of the different uses of the numeral "1".) I may know where a thing is and then point to it by virtue of that knowledge. The knowledge tells me where to point to. We here conceived this knowledge as the condition for deliberately pointing to the object. Thus one can say: "I can point to the spot you mean because I see it", "I can direct you to the place because I know where it is; first turning to the right, etc." Now one is inclined to say "I must know where a thing is before I can point to it". Perhaps you will feel less happy about saying: "I must know where a thing is before I can

look at it". Sometimes of course it is correct to say this. But we are tempted to think that there is one particular psychical state or event, the knowledge of the place, which must precede every deliberate act of pointing, moving towards, etc. Think of the analogous case: "One can only obey an order after having understood it".

Page 50

If I point to the painful spot on my arm, in what sense can I be said to have known where the pain was before I pointed to the place? Before I pointed I could have said "The pain is in my left arm". Supposing my arm had been covered with a meshwork of lines numbered in such a way that I could refer to any place on its surface. Was it necessary that I should have been able to describe the painful spot by means of these coordinates before I could point to it? What I wish to say is that the act of pointing *determines* a place of pain. This act of pointing, by the way, is not to be confused with that of finding the painful spot by probing. In fact the two may lead to different results.

Page 50

An innumerable variety of cases can be thought of in which we should say that someone has pains in another person's body; or, say,

Page Break 51

in a piece of furniture, or in any empty spot. Of course we mustn't forget that a pain in a particular part of our body, e.g., in an upper tooth, has a peculiar tactile and kinaesthetic neighbourhood. Moving our hand upward a little distance we touch our eye; and the word "little distance" here refers to tactile distance or kinaesthetic distance, or both. (It is easy to imagine tactile and kinaesthetic distances correlated in ways different from the usual. The distance from our mouth to our eye might seem very great 'to the muscles of our arm' when we move our finger from the mouth to the eye. Think how large you imagine the cavity in your tooth when the dentist is drilling and probing it.)

Page 51

When I said that if we moved our hand upward a little, we touch our eye, I was referring to tactile evidence only. That is, the criterion for my finger touching my eye was to be only that I had the particular feeling which would have made me say that I was touching my eye, even if I had no visual evidence for it, and even if, on looking into a mirror, I saw my finger not touching my eye, but, say, my forehead. Just as the 'little distance' I referred to was a tactile or kinaesthetic one, so also the places of which I said, "they lie a little distance apart" were tactile places. To say that my finger in tactile and kinaesthetic space moves from my tooth to my eye then means that I have those tactile and kinaesthetic experiences which we normally have when we say "my finger moves from my tooth to my eye". But what we regard as evidence for this latter proposition is, as we all know, by no means only tactile and kinaesthetic. In fact if I had the tactile and kinaesthetic sensations referred to, I might still deny the proposition "my finger moves etc...." because of what I saw. That proposition is a proposition about physical objects. (And now don't think that the expression "physical objects" is meant to distinguish one kind of object from another.) The grammar of propositions which we call propositions about physical objects admits of a variety of evidences for every such proposition. It characterizes the grammar of the proposition "my finger moves, etc." that I regard the propositions "I see it move", "I feel it move", "He sees it move", "He tells me that it moves", etc. as evidences for it. Now if I say "I see my hand move", this at first sight seems to presuppose that I agree with the proposition "my hand moves". But if I regard the proposition "I see my hand move" as one of the evidences for the proposition "my hand moves", the truth of the latter is, of course, not presupposed in the truth of the former. One might therefore suggest the expression "It looks as

Page Break 52

though my hand were moving" instead of "I see my hand moving". But this expression, although it indicates that my hand may appear to be moving without really moving, might still suggest that after all there must be a hand in order that it should appear to be moving; whereas we could easily imagine cases in which the proposition describing the visual evidence is true and at the same time other evidences make us say that I have no hand. Our ordinary way of expression obscures this. We are handicapped in ordinary language by having to describe, say, a tactile sensation by means of terms for physical objects such as the word "eye", "finger", etc., when what we want to say does not entail the existence of an eye or finger, etc.. We have to use a roundabout description of our sensations. This of course does not mean that ordinary language is insufficient for our special purposes, but that it is slightly cumbrous and sometimes misleading. The reason for this peculiarity of our language is of course the regular coincidence of certain sense experiences. Thus when I feel my arm moving I mostly also can see it moving. And if I touch it with my hand, also that hand feels the motion, etc. (The man whose foot has been amputated will describe a particular pain as pain in his foot.) We feel in such cases a strong need for such an expression as: "a sensation travels from my tactual cheek to my tactual eye". I said all this because, if you are aware of the tactual and kinaesthetic environment of a pain, you may find a difficulty in imagining that one could have toothache anywhere else than in one's own teeth. But if we imagine such a case, this simply means that we imagine a correlation between visual, tactual, kinaesthetic,

etc., experiences different from the ordinary correlation. Thus we can imagine a person having the sensation of toothache plus those tactual and kinaesthetic experiences which are normally bound up with seeing his hand travelling from *his* tooth to his nose, to his eyes, etc., but correlated to the visual experience of his hand moving to those places in another person's face. Or again, we can imagine a person having the kinaesthetic sensation of moving his hand, and the tactual sensation, in his fingers and face, of his fingers moving over his face, whereas his kinaesthetic and visual sensations should have to be described as those of his fingers moving over his knee. If we had a sensation of toothache plus certain tactual and kinaesthetic sensations usually characteristic of touching the painful tooth and neighbouring parts of our face, and if these sensations were accompanied by seeing my hand touch, and move about on, the edge of my table, we should feel doubtful whether to call this

Page Break 53

experience an experience of toothache in the table or not. If, on the other hand, the tactual and kinaesthetic sensations described were correlated to the visual experience of seeing my hand touch a tooth and other parts of the face of another person, there is no doubt that I would call this experience "toothache in another person's tooth".

Page 53

I said that the man who contended that it was impossible to feel the other person's pain did not thereby wish to deny that one person could feel pain in another person's body. In fact, he would have said: "I may have toothache in another man's tooth, but not his toothache".

Page 53

Thus the propositions "A has a gold tooth" and "A has toothache" are not used analogously. They differ in their grammar where at first sight they might not seem to differ.

Page 53

As to the use of the word "imagine"-one might say: "Surely there is quite a definite act of imagining the other person to have pain". Of course we don't deny this, or any other statement about facts. But let us see: If we make an image of the other person's pain, do we apply it in the same way in which we apply the image, say, of a black eye, when we imagine the other person having one? Let us again replace imagining, in the ordinary sense, by making a painted image. (This could quite well be *the* way certain beings did their imagining.) Then let a man imagine in this way that A has a black eye. A very important application of this picture will be comparing it with the real eye to see if the picture is correct. When we vividly imagine that someone suffers pain, there often enters in our image what one might call a shadow of a pain felt in the locality corresponding to that in which we say his pain is felt. But the sense in which an image is an image is determined by the way in which it is compared with reality. This we might call the method of projection. Now think of comparing an image of A's toothache with his toothache. How would you compare them? If you say, you compare them 'indirectly' via his bodily behaviour, I answer that this means you *don't* compare them as you compare the picture of his behaviour with his behaviour.

Page 53

Again, when you say, "I grant you that you can't *know* when A has pain, you can only conjecture it", you don't see the difficulty which lies in the different uses of the words "conjecturing" and "knowing". What sort of impossibility were you referring to when you said you *couldn't* know? Weren't you thinking of a case analogous to that when one couldn't know whether the other man had a gold tooth in his mouth because he had his mouth shut? Here what you didn't know you could nevertheless imagine knowing; it made sense to say that you

Page Break 54

saw that tooth although you didn't see it; or rather, it makes sense to say that you don't see his tooth and therefore it also makes sense to say that you do. When on the other hand, you granted me that a man can't *know* whether the other person has pain, you do not wish to say that as a matter of fact people didn't know, but that it made no sense to say they knew (and therefore no sense to say they don't know). If therefore in this case you use the term "conjecture" or "believe", you don't use it as opposed to "know". That is, you did not state that knowing was a goal which you could not reach, and that you have to be contented with conjecturing; rather, there is no goal in this game. Just as when one says "You can't count through the whole series of cardinal numbers", one doesn't state a fact about human frailty but about a convention which we have made. Our statement is not comparable, though always falsely compared, with such a one as "it is impossible for a human being to swim across the Atlantic"; but it *is* analogous to a statement like "there is no goal in an endurance race". And this is one of the things which the person feels dimly who is not satisfied with the explanation that though you can't know... you can conjecture....

Page 54

If we are angry with someone for going out on a cold day with a cold in his head, we sometimes say: "I won't feel your cold". And this can mean: "I don't suffer when you catch a cold". This is a proposition taught by experience. For we could imagine a, so to speak, wireless connection between the two bodies which made one

person feel pain in his head when the other had exposed his to the cold air. One might in this case argue that the pains are mine because they are felt in my head; but suppose I and someone else had a part of our bodies in common, say a hand. Imagine the nerves and tendons of my arm and A's connected to this hand by an operation. Now imagine the hand stung by a wasp. Both of us cry, contort our faces, give the same description of the pain, etc. Now are we to say we have the same pain or different ones? If in such a case you say: "We feel pain in the same place, in the same body, our descriptions tally, but still my pain can't be his", I suppose as a reason you will be inclined to say: "because my pain is my pain and his pain is his pain". And here you are making a grammatical statement about the use of such a phrase as "the same pain". You say that you don't wish to apply the phrase, "he has got my pain" or "we both have the same pain", and instead, perhaps, you will apply such a phrase as "his pain is exactly like mine". (It would be no argument to say that the two couldn't have the same pain

Page Break 55

because one might anaesthetize or kill one of them while the other still felt pain.) Of course, if we exclude the phrase "I have his toothache" from our language, we thereby also exclude "I have (or feel) *my* toothache". Another form of our metaphysical statement is this: "A man's sense data are private to himself". And this way of expressing it is even more misleading because it looks still more like an experiential proposition; the philosopher who says this may well think that he is expressing a kind of scientific truth.

Page 55

We use the phrase "two books have the *same* colour", but we could perfectly well say: "They can't have the *same* colour, because, after all, this book has its own colour, and the other book has its own colour too". This also would be stating a grammatical rule—a rule, incidentally, not in accordance with our ordinary usage. The reason why one should think of these two different usages at all is this: We compare the case of sense data with that of physical bodies, in which case we make a distinction between: "this is the same chair that I saw an hour ago" and "this is not the same chair, but one exactly like the other". Here it makes sense to say, and it is an experiential proposition: "A and B couldn't have seen the same chair, for A was in London and B in Cambridge; they saw two chairs exactly alike". (Here it will be useful if you consider the different criteria for what we call the "identity of these objects". How do we apply the statements: "This is the same day...", "This is the same word...", "This is the same occasion...", etc.?)

Page 55

What we did in these discussions was what we always do when we meet the word "can" in a metaphysical proposition. We show that this proposition hides a grammatical rule. That is to say, we destroy the outward similarity between a metaphysical proposition and an experiential one, and we try to find the form of expression which fulfils a certain craving of the metaphysician which our ordinary language does not fulfil and which, as long as it isn't fulfilled, produces the metaphysical puzzlement. Again, when in a metaphysical sense I say "I *must* always know when I have pain", this simply makes the word "know" redundant; and instead of "I know that I have pain", I can simply say "I have pain". The matter is different, of course, if we give the phrase "unconscious pain" sense by fixing experiential criteria for the case in which a man has pain and doesn't know it, and if then we say (rightly or wrongly) that as a matter of fact nobody has ever had pains which he didn't know of.

Page 55

When we say "I can't feel his pain", the idea of an insurmountable

Page Break 56

barrier suggests itself to us. Let us think straight away of a similar case: "The colours green and blue can't be in the same place simultaneously". Here the picture of physical impossibility which suggests itself is, perhaps, not that of a barrier; rather we feel that the two colours are in each other's way. What is the origin of this idea?—We say three people can't sit side by side on this bench; they have no room. Now the case of the colours is not analogous to this; but it is somewhat analogous to saying: "3 × 18 inches won't go into 3 feet". This is a grammatical rule and states a logical impossibility. The proposition "three men can't sit side by side on a bench a yard long" states a physical impossibility; and this example shows clearly why the two impossibilities are confused. (Compare the proposition "He is 6 inches taller than I" with "6 foot is 6 inches longer than 5 foot 6". These propositions are of utterly different kinds, but look exactly alike.) The reason why in these cases the idea of physical impossibility suggests itself to us is that on the one hand we decide against using a particular form of expression, on the other hand we are strongly tempted to use it, since (a) it sounds English, or German, etc., all right, and (b) there are closely similar forms of expression used in other departments of our language. We have decided against using the phrase "They are in the same place"; on the other hand this phrase strongly recommends itself to us through the analogy with other phrases, so that, in a sense, we have to turn this form of expression out by force. And this is why we seem to ourselves to be rejecting a universally false proposition. We make a picture like that of the two colours being in each other's way, or

that of a barrier which doesn't allow one person to come closer to another's experience than to the point of observing his behaviour; but on looking closer we find that we can't apply the picture which we have made.

Page 56

Our wavering between logical and physical impossibility makes us make such statements as this: "If what I feel is always *my* pain only, what can the supposition mean that someone else has pain?" The thing to do in such cases is always to look how the words in question *are actually used in our language*. We are in all such cases thinking of a use different from that which our ordinary language makes of the words. Of a use, on the other hand, which just then for some reason strongly recommends itself to us. When something seems queer about the grammar of our words, it is because we are alternately tempted to use a word in several different ways. And it is particularly difficult to discover that an assertion which the metaphysician makes expresses

Page Break 57

discontentment with our grammar when the words of this assertion can also be used to state a fact of experience. Thus when he says "only my pain is real pain", this sentence might mean that the other people are only pretending. And when he says "this tree doesn't exist when nobody sees it", this might mean: "this tree vanishes when we turn our backs to it". The man who says "only my pain is real", doesn't mean to say that he has found out by the common criteria--the criteria, i.e., which give our words their common meanings--that the others who said they had pains were cheating. But what he rebels against is the use of *this* expression in connection with *these* criteria. That is, he objects to using this word in the particular way in which it is commonly used. On the other hand, he is not aware that he is objecting to a convention. He sees a way of dividing the country different from the one used on the ordinary map. He feels tempted, say, to use the name "Devonshire" not for the county with its conventional boundary, but for a region differently bounded. He could express this by saying: "Isn't it absurd to make *this* a county, to draw the boundaries *here*?" But what he says is: "The *real* Devonshire is this". We could answer: "What you want is only a new notation, and by a new notation no facts of geography are changed". It is true, however, that we may be irresistibly attracted or repelled by a notation. (We easily forget how much a notation, a form of expression, may mean to us, and that changing it isn't always as easy as it often is in mathematics or in the sciences. A change of clothes or of names may mean very little and it may mean a great deal.)

Page 57

I shall try to elucidate the problem discussed by realists, idealists, and solipsists by showing you a problem closely related to it. It is this: "Can we have unconscious thoughts, unconscious feelings, etc.?" The idea of there being unconscious thoughts has revolted many people. Others again have said that these were wrong in supposing that there could only be conscious thoughts, and that psychoanalysis had discovered unconscious ones. The objectors to unconscious thought did not see that they were not objecting to the newly discovered psychological reactions, but to the way in which they were described. The psychoanalysts on the other hand were misled by their own way of expression into thinking that they had done more than discover new psychological reactions; that they had, in a sense, discovered conscious thoughts which were unconscious. The first could have stated their objection by saying "We don't wish to use the phrase 'unconscious thoughts'; we wish to reserve the word '*thought*' for

Page Break 58

what you call 'conscious thoughts'". They state their case wrongly when they say: "There can only be conscious thoughts and no unconscious ones". For if they don't wish to talk of "unconscious thought" they should not use the phrase "conscious thought", either.

Page 58

But is it not right to say that in any case the person who talks both of conscious and unconscious thoughts thereby uses the word "thoughts" in two different ways?--Do we use a hammer in two different ways when we hit a nail with it and, on the other hand, drive a peg into a hole? And do we use it in two different ways or in the same way when we drive this peg into this hole and, on the other hand, another peg into another hole? Or should we only call it different uses when in one case we drive something into something and in the other, say, we smash something? Or is this all using the hammer in one way and is it to be called a different way only when we use the hammer as a paper weight?--In which cases are we to say that a word is used in two different ways and in which that it is used in one way? To say that a word is used in two (or more) different ways does in itself not yet give us any idea about its use. It only specifies a way of looking at this usage by providing a schema for its description with two (or more) subdivisions. It is all right to say: "I do *two* things with this hammer: I drive a nail into this board and one into that board". But I could also have said: "I am doing only one thing with this hammer; I am driving a nail into this board and one into that board". There can be two kinds of discussions as to whether a word is used in one way or in two ways: (a) Two people may discuss whether the English word "cleave" is only used for chopping up something or also for joining things together. This is a discussion about the facts of a certain actual usage. (b) They

may discuss whether the word "altus", standing for both "deep" and "high", is *thereby* used in two different ways. This question is analogous to the question whether the word "thought" is used in two ways or in one when we talk of conscious and unconscious thought. The man who says "surely, these are two different usages" has already decided to use a two-way schema, and what he said expressed this decision.

Page 58

Now when the solipsist says that only his own experiences are real, it is no use answering him: "Why do you tell us this if you don't believe that we really hear it?" Or anyhow, if we give him this answer, we mustn't believe that we have answered his difficulty. There is no common sense answer to a philosophical problem. One can defend common sense against the attacks of philosophers only by solving

Page Break 59

their puzzles, i.e., by curing them of the temptation to attack common sense; not by restating the views of common sense. A philosopher is not a man out of his senses, a man who doesn't see what everybody sees; nor on the other hand is his disagreement with common sense that of the scientist disagreeing with the coarse views of the man in the street. That is, his disagreement is not founded on a more subtle knowledge of fact. We therefore have to look round for the *source* of his puzzlement. And we find that there is puzzlement and mental discomfort, not only when our curiosity about certain facts is not satisfied or when we can't find a law of nature fitting in with all our experience, but also when a notation dissatisfies us--perhaps because of various associations which it calls up. Our ordinary language, which of all possible notations is the one which pervades all our life, holds our mind rigidly in one position, as it were, and in this position sometimes it feels cramped, having a desire for other positions as well. Thus we sometimes wish for a notation which stresses a difference more strongly, makes it more obvious, than ordinary language does, or one which in a particular case uses more closely similar forms of expression than our ordinary language. Our mental cramp is loosened when we are shown the notations which fulfil these needs. These needs can be of the greatest variety.

Page 59

Now the man whom we call a solipsist and who says that only his own experiences are real, does not thereby disagree with us about any practical question of fact, he does not say that we are simulating when we complain of pains, he pities us as much as anyone else, and at the same time he wishes to restrict the use of the epithet "real" to what we should call his experiences; and perhaps he doesn't want to call our experiences "experiences" at all (again without disagreeing with us about any question of fact). For he would say that it was *inconceivable* that experiences other than his own were real. He ought therefore to use a notation in which such a phrase as "A has real toothache" (where A is not he) is meaningless, a notation whose rules exclude this phrase as the rules of chess exclude a pawn's making a knight's move. The solipsist's suggestion comes to using such a phrase as "there is real toothache" instead of "Smith (the solipsist) has toothache". And why shouldn't we grant him this notation? I needn't say that in order to avoid confusion he had in this case better not use the word "real" as opposed to "simulated" at all; which just means that we shall have to provide for the distinction "real"/"simulated" in some other way. The solipsist who says

Page Break 60

"only I feel real pain", "only I really see (or hear)" is not stating an opinion; and that's why he is so sure of what he says. He is irresistibly tempted to use a certain form of expression; but we must yet find *why* he is.

Page 60

The phrase "only I really see" is closely connected with the idea expressed in the assertion "we never know what the other man really sees when he looks at a thing" or this, "we can never know whether he calls the same thing 'blue' which we call 'blue' ". In fact we might argue: "I can never know what he sees or that he sees at all, for all I have is signs of various sorts which he gives me; therefore it is an unnecessary hypothesis altogether to say that he sees; what seeing is I only know from seeing myself; I have only learnt the word 'seeing' to mean what *I* do". Of course this is just not true, for I have definitely learned a different and much more complicated use of the word "to see" than I here profess. Let us make clear the tendency which guided me when I did so, by an example from a slightly different sphere: Consider this argument: "How can we wish that this paper were red if it isn't red? Doesn't this mean that I wish that which doesn't exist at all? Therefore my wish can only contain something *similar* to the paper's being red. Oughtn't we therefore to use a different word instead of 'red' when we talk of wishing that something were red? The imagery of the wish surely shows us something less definite, something hazier, than the reality of the paper being red. I should therefore say, instead of 'I wish this paper were red', something like 'I wish a pale red for this paper' ". But if in the usual way of speaking he had said, "I wish a pale red for this paper," we should, in order to fulfil his wish, have painted it a pale red--and this wasn't what he wished. On the other hand there is no objection to adopting the form of expression which he suggests as long as we know that he uses the phrase "I wish a pale *x* for this paper", always to mean what ordinarily we express by "I wish this paper had the colour *x*".

What he said really recommended his notation, in the sense in which a notation can be recommended. But he did not tell us a new truth and did not show us that what we said before was false. (All this connects our present problem with the problem of negation. I will only give you a hint, by saying that a notation would be possible in which, to put it roughly, a quality had always two names, one for the case when something is said to have it, the other for the case when something is said not to have it. The negation of "This paper is red" could then be, say, "This paper is not rode". Such a notation would actually fulfil some of the

Page Break 61

wishes which are denied us by our ordinary language and which sometimes produce a cramp of philosophical puzzlement about the idea of negation.)

Page 61

The difficulty which we express by saying "I can't know what he sees when he (truthfully) says that he sees a blue patch" arises from the idea that "knowing what he sees" means: "seeing that which he also sees"; not, however, in the sense in which we do so when we both have the same object before our eyes: but in the sense in which the object seen would be an object, say, in his head, or in *him*. The idea is that the same object may be before his eyes and mine, but that I can't stick my head into his (or my mind into his, which comes to the same) so that the *real* and *immediate* object of his vision becomes the real and immediate object of my vision too. By "I don't know what he sees" we really mean "I don't know what he looks at", where 'what he looks at' is hidden and he can't show it to me; it is *before his mind's eye*. Therefore, in order to get rid of this puzzle, examine the grammatical difference between the statements "I don't know what he sees" and "I don't know what he looks at", as they are actually used in our language.

Page 61

Sometimes the most satisfying expression of our solipsism seems to be this: "When anything is seen (really *seen*), it is always I who see it".

Page 61

What should strike us about this expression is the phrase "always I". Always *who?*--For, queer enough, I don't mean: "always L. W." This leads us to considering the criteria for the identity of a person. Under what circumstances do we say: "This is the same person whom I saw an hour ago"? Our actual use of the phrase "the same person" and of the name of a person is based on the fact that many characteristics which we use as the criteria for identity coincide in the vast majority of cases. I am as a rule recognized by the appearance of my body. My body changes its appearance only gradually and comparatively little, and likewise my voice, characteristic habits, etc. only change slowly and within a narrow range. We are inclined to use personal names in the way we do, only as a consequence of these facts. This can best be seen by imagining unreal cases which show us what different 'geometries' we would be inclined to use if facts were different. Imagine, e.g., that all human bodies which exist looked alike, that on the other hand, different sets of characteristics seemed, as it were, to change their habitation among these bodies. Such a set of characteristics might be, say, mildness, together with a high pitched voice, and slow movements, or a choleric temperament, a deep voice, and jerky movements, and such like. Under such circumstances, although

Page Break 62

it would be possible to give the bodies names, we should perhaps be as little inclined to do so as we are to give names to the chairs of our dining-room set. On the other hand, it might be useful to give names to the sets of characteristics, and the use of these names would now *roughly* correspond to the personal names in our present language.

Page 62

Or imagine that it were usual for human beings to have two characters, in this way: People's shape, size and characteristics of behaviour periodically undergo a complete change. It is the usual thing for a man to have two such states, and he lapses suddenly from one into the other. It is very likely that in such a society we should be inclined to christen every man with two names, and perhaps to talk of the pair of persons in his body. Now were Dr. Jekyll and Mr. Hyde two persons or were they the same person who merely changed? We can say whichever we like. We are not forced to talk of a double personality.

Page 62

There are many uses of the word "personality" which we may feel inclined to adopt, all more or less akin. The same applies when we define the identity of a person by means of his memories. Imagine a man whose memories on the even days of his life comprise the events of all these days, skipping entirely what happened on the odd days. On the other hand, he remembers on an odd day what happened on previous odd days, but his memory then skips the even days without a feeling of discontinuity. If we like we can also assume that he has alternating

appearances and characteristics on odd and even days. Are we bound to say that here two persons are inhabiting the same body? That is, is it right to say that there are, and wrong to say that there aren't, or vice versa? Neither. For the ordinary use of the word "person" is what one might call a composite use suitable under the ordinary circumstances. If I assume, as I do, that these circumstances are changed, the application of the term "person" or "personality" has thereby changed; and if I wish to preserve this term and give it a use analogous to its former use, I am at liberty to choose between many uses, that is, between many different kinds of analogy. One might say in such a case that the term "personality" hasn't got one legitimate heir only. (This kind of consideration is of importance in the philosophy of mathematics. Consider the use of the words "proof", "formula", and others. Consider the question: "Why should what we do here be called 'philosophy'? Why should it be regarded as the only legitimate heir of the different activities which had this name in former times?")

Page Break 63

Page 63

Now let us ask ourselves what sort of identity of personality it is we are referring to when we say "when anything is seen, it is always I who see". What is it I want all these cases of seeing to have in common? As an answer I have to confess to myself that it is not my bodily appearance. I don't always see part of my body when I see. And it isn't essential that my body, if seen amongst the things I see, should always look the same. In fact I don't mind how much it changes. And I feel the same way about all the properties of my body, the characteristics of my behaviour, and even about my memories.--When I think about it a little longer I see that what I wished to say was: "Always when anything is seen, something is seen". I.e., that of which I said it continued during all the experiences of seeing was not any particular entity "I", but the experience of seeing itself. This may become clearer if we imagine the man who makes our solipsistic statement to point to his eyes while he says "I". (Perhaps because he wishes to be exact and wants to say expressly which eyes belong to the mouth which says "I" and to the hands pointing to his own body). But what is he pointing to? These particular eyes with the identity of physical objects? (To understand this sentence, you must remember that the grammar of words of which we say that they stand for physical objects is characterized by the way in which we use the phrase "the same so-and-so", or "the identical so-and-so", where "so-and-so" designates the physical object.) We said before that he did not wish to point to a particular physical object at all. The idea that he had made a significant statement arose from a confusion corresponding to the confusion between what we shall call "the geometrical eye" and "the physical eye". I will indicate the use of these terms: If a man tries to obey the order "Point to your eye", he may do many different things, and there are many different criteria which he will accept for having pointed to his eye. If these criteria, as they usually do, coincide, I may use them alternately and in different combinations to show me that I have touched my eye. If they don't coincide, I shall have to distinguish between different senses of the phrase "I touch my eye" or "I move my finger towards my eye". If, e.g., my eyes are shut, I can still have the characteristic kinaesthetic experience in my arm which I should call the kinaesthetic experience of raising my hand to my eye. That I had succeeded in doing so, I shall recognize by the peculiar tactile sensation of touching my eye. But if my eye were behind a glass plate fastened in such a way that it prevented me from exerting a pressure on my eye with my

Page Break 64

finger, there would still be a criterion of muscular sensation which would make me say that now my finger was in front of my eye. As to visual criteria, there are two I can adopt. There is the ordinary experience of seeing my hand rise and come towards my eye, and this experience, of course, is different from seeing two things meet, say, two finger tips. On the other hand, I can use as a criterion for my finger moving towards my eye, what I see when I look into a mirror and see my finger nearing my eye. If that place on my body which, we say, 'sees' is to be determined by moving my finger towards my eye, according to the second criterion, then it is conceivable that I may see with what according to other criteria is the tip of my nose, or places on my forehead; or I might in this way point to a place lying outside my body. If I wish a person to point to his eye (or his eyes) according to the second criterion *alone*, I shall express my wish by saying: "Point to your geometrical eye (or eyes)". The grammar of the word "geometrical eye" stands in the same relation to the grammar of the word "physical eye" as the grammar of the expression "the visual sense datum of a tree" to the grammar of the expression "the physical tree". In either case it confuses everything to say "the one is a *different kind* of object from the other"; for those who say that a sense datum is a different kind of object from a physical object misunderstand the grammar of the word "kind", just as those who say that a number is a different kind of object from a numeral. They think they are making such a statement as "A railway train, a railway station, and a railway car are different kinds of objects", whereas their statement is analogous to "A railway train, a railway accident, and a railway law are different kinds of objects".

Page 64

What tempted me to say "it is always I who see when anything is seen", I could also have yielded to by

saying: "whenever anything is seen, it is *this* which is seen", accompanying the word "this" by a gesture embracing my visual field (but not meaning by "this" the particular objects which I happen to see at the moment). One might say, "I am pointing at the visual field as such, not at anything in it". And this only serves to bring out the senselessness of the former expression.

Page 64

Let us then discard the "always" in our expression. Then I can still express my solipsism by saying, "Only what *I* see (or: see now) is really seen". And here I am tempted to say: "Although by the word 'I' I don't mean L. W., it will do if the others understand 'I' to mean L. W., if just now I am in fact L. W." I could also express my claim by

Page Break 65

saying: "I am the vessel of life"; but mark, it is essential that everyone to whom I say this should be unable to understand me. It is essential that the other should not be able to understand 'what *I* really *mean*', though in practice he might do what I wish by conceding to me an exceptional position in his notation. But I wish it to be *logically* impossible that he should understand me, that is to say, it should be meaningless, not false, to say that he understands me. Thus my expression is one of the many which is used on various occasions by philosophers and supposed to convey something to the person who says it, though essentially incapable of conveying anything to anyone else. Now if for an expression to convey a meaning means to be accompanied by or to produce certain experiences, our expression may have all sorts of meanings, and I don't wish to say anything about them. But we are, as a matter of fact, misled into thinking that our expression has a meaning in the sense in which a non-metaphysical expression has; for we wrongly compare our case with one in which the other person can't understand what we say because he lacks a certain information. (This remark can only become dear if we understand the connection between grammar and sense and nonsense.)

Page 65

The meaning of a phrase for us is characterized by the use we make of it. The meaning is not a mental accompaniment to the expression. Therefore the phrase "I think I mean something by it", or "I'm sure I mean something by it", which we so often hear in philosophical discussions to justify the use of an expression is for us no justification at all. We ask: "*What* do you mean?", i.e., "How do you use this expression?" If someone taught me the word "bench" and said that he sometimes or always put a stroke over it thus: "**bench**", and that this meant something to him, I should say: "I don't know what sort of idea you associate with this stroke, but it doesn't interest me unless you show me that there is a use for the stroke in the kind of calculus in which you wish to use the word 'bench'".--I want to play chess, and a man gives the white king a paper crown, leaving the use of the piece unaltered, but telling me that the crown has a meaning to him in the game, which he can't express by rules. I say: "as long as it doesn't alter the use of the piece, it hasn't what I call a meaning".

Page 65

One sometimes hears that such a phrase as "This is here", when while I say it I point to a part of my visual field, has a kind of primitive meaning to me, although it can't impart information to anybody else.

Page 65

When I say "Only this is seen", I forget that a sentence may come ever so natural to us without having any use in our calculus of language.

Page Break 66

Think of the law of identity, " $a = a$ ", and of how we sometimes try hard to get hold of its sense, to visualize it, by looking at an object and repeating to ourselves such a sentence as "This tree is the same thing as this tree". The gestures and images by which I apparently give this sentence sense are very similar to those which I use in the case of "Only *this* is really seen". (To get clear about philosophical problems, it is useful to become conscious of the apparently unimportant details of the particular situation in which we are inclined to make a certain metaphysical assertion. Thus we may be tempted to say "Only this is really seen" when we stare at unchanging surroundings, whereas we may not at all be tempted to say this when we look about us while walking.)

Page 66

There is, as we have said, no objection to adopting a symbolism in which a certain person always or temporarily holds an exceptional place. And therefore, if I utter the sentence "Only I really see", it is conceivable that my fellow creatures thereupon will arrange their notation so as to fall in with me by saying "so-and-so is really seen" instead of "L. W. sees so-and-so", etc., etc. What, however, is wrong, is to think that I can *justify* this choice of notation. When I said, from my heart, that only I see, I was also inclined to say that by "I" I didn't really mean L. W., although for the benefit of my fellow men I might say "It is now L. W. who really sees" though this is not what I really mean. I could almost say that by "I" I mean something which just now inhabits L. W., something which the others can't see. (I meant my mind, but could only point to it via my body.) There is nothing wrong in suggesting

that the others should give me an exceptional place in their notation; but the justification which I wish to give for it: that this body is now the seat of that which really lives--is senseless. For admittedly this is not to state anything which in the ordinary sense is a matter of experience. (And don't think that it is an experiential proposition which only I can know because only I am in the position to have the particular experience.) Now the idea that the real I lives in my body is connected with the peculiar grammar of the word "I", and the misunderstandings this grammar is liable to give rise to. There are two different cases in the use of the word "I" (or "my") which I might call "the use as object" and "the use as subject". Examples of the first kind of use are these: "My arm is broken", "I have grown six inches", "I have a bump on my forehead", "The wind blows my hair about". Examples of the second kind are: "I see so-and-so", "I hear so-and-so", "I try to lift my arm", "I think it will

Page Break 67

rain", "I have toothache". One can point to the difference between these two categories by saying: The cases of the first category involve the recognition of a particular person, and there is in these cases the possibility of an error, or as I should rather put it: The possibility of an error has been provided for. The possibility of failing to score has been provided for in a pin game. On the other hand, it is not one of the hazards of the game that the balls should fail to come up if I have put a penny in the slot. It is possible that, say in an accident, I should feel a pain in my arm, see a broken arm at my side, and think it is mine, when really it is my neighbour's. And I could, looking into a mirror, mistake a bump on his forehead for one on mine. On the other hand, there is no question of recognizing a person when I say I have toothache. To ask "are you sure that it's *you* who have pains?" would be nonsensical. Now, when in this case no error is possible, it is because the move which we might be inclined to think of as an error, a 'bad move', is no move of the game at all. (We distinguish in chess between good and bad moves, and we call it a mistake if we expose the queen to a bishop. But it is no mistake to promote a pawn to a king.) And now this way of stating our idea suggests itself: that it is as impossible that in making the statement "I have toothache" I should have mistaken another person for myself, as it is to moan with pain by mistake, having mistaken someone else for me. To say, "I have pain" is no more a statement *about* a particular person than moaning is. "But surely the word 'I' in the mouth of a man refers to the man who says it; it points to himself; and very often a man who says it actually points to himself with his finger". But it was quite superfluous to point to himself. He might just as well only have raised his hand. It would be wrong to say that when someone points to the sun with his hand, he is pointing both to the sun and himself because it is *he* who points; on the other hand, he may by pointing attract attention both to the sun and to himself.

Page 67

The word "I" does not mean the same as "L. W." even if I am L. W., nor does it mean the same as the expression "the person who is now speaking". But that doesn't mean: that "L. W." and "I" mean different things. All it means is that these words are different instruments in our language.

Page 67

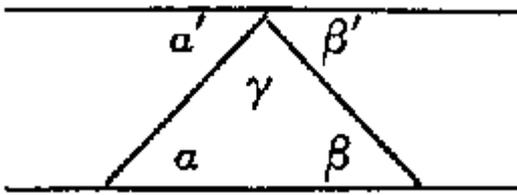

Think of words as instruments characterized by their use, and then think of the use of a hammer, the use of a chisel, the use of a square, of a glue pot, and of the glue. (Also, all that we say here can be understood only if one understands that a great variety of games is played

Page Break 68

with the sentences of our language: Giving and obeying orders; asking questions and answering them; describing an event; telling a fictitious story; telling a joke; describing an immediate experience; making conjectures about events in the physical world; making scientific hypotheses and theories; greeting someone, etc., etc.) The mouth which says "I" or the hand which is raised to indicate that it is I who wish to speak, or I who have toothache, does not thereby point to anything. If, on the other hand, I wish to indicate the *place* of my pain, I point. And here again remember the difference between pointing to the painful spot without being led by the eye and on the other hand pointing to a scar on my body after looking for it. ("That's where I was vaccinated".)--The man who cries out with pain, or says that he has pain, *doesn't choose the mouth which says it*.

Page 68

All this comes to saying that the person of whom we say "he has pain" is, by the rules of the game, the person who cries, contorts his face, etc. The place of the pain--as we have said--may be in another person's body. If, in saying "I", I point to my own body, I model the use of the word "I" on that of the demonstrative "this person" or "he". (This way of making the two expressions similar is somewhat analogous to that which one sometimes adopts in mathematics, say in the proof that the sum of the three angles of a triangle is 180°.

We say " $\alpha = \alpha'$, $\beta = \beta'$, and $\gamma = \gamma$ ". The first two equalities are of an entirely different kind from the third.) In "I have pain", "I" is not a demonstrative pronoun.

Page 68

Compare the two cases: 1. "How do you know that *he* has pains?"--"Because I hear him moan". 2. "How do you know that you have pains?"--"Because I *feel* them". But "I feel them" means the same as "I have them". Therefore this was no explanation at all. That, however, in my answer I am inclined to stress the word "feel" and not the word "I" indicates that by "I" I don't wish to pick out one person (from amongst different persons).

Page 68

The difference between the propositions "I have pain" and "he has pain" is not that of "L. W. has pain" and "Smith has pain". Rather, it corresponds to the difference between moaning and saying that someone moans.--"But surely the word 'I' in 'I have pain' serves to

Page Break 69

distinguish me from other people, because it is by the sign 'I' that I distinguish saying that I have pain from saying that one of the others has". Imagine a language in which, instead of "I found nobody in the room", one said "I found Mr. Nobody in the room". Imagine the philosophical problems which would arise out of such a convention. Some philosophers brought up in this language would probably feel that they didn't like the similarity of the expressions "Mr. Nobody" and "Mr. Smith". When we feel that we wish to abolish the "I" in "I have pain", one may say that we tend to make the verbal expression of pain similar to the expression by moaning.--We are inclined to forget that it is the particular use of a word only which gives the word its meaning. Let us think of our old example for the use of words: Someone is sent to the grocer with a slip of paper with the words "five apples" written on it. The use of the word *in practice* is its meaning. Imagine it were the usual thing that the objects around us carried labels with words on them by means of which our speech referred to the objects. Some of these words would be proper names of the objects, others generic names (like table, chair, etc.), others again, names of colours, names of shapes, etc. That is to say, a label would only have a meaning to us in so far as we made a particular use of it. Now we could easily imagine ourselves to be impressed by merely seeing a label on a thing, and to forget that what makes these labels important is their use. In this way we sometimes believe that we have named something when we make the gesture of pointing and utter words like "This is..." (the formula of the ostensive definition). We say we call something "toothache", and think that the word has received a definite function in the dealings we carry out with language when, under certain circumstances, we have pointed to our cheek and said: "This is toothache". (Our idea is that when we point and the other "only knows what we are pointing to" he knows the use of the word. And here we have in mind the special case when 'what we point to' is, say, a person and "to know that I point to" means to see which of the persons present I point to.)

Page 69

We feel then that in the cases in which "I" is used as subject, we don't use it because we recognize a particular person by his bodily characteristics; and this creates the illusion that we use this word to refer to something bodiless, which, however, has its seat in our body. In fact *this* seems to be the real ego, the one of which it was said, "Cogito, ergo sum".--"Is there then no mind, but only a body?" Answer: The word "mind" has meaning, i.e., it has a use in our

Page Break 70

language; but saying this doesn't yet say what kind of use we make of it.

Page 70

In fact one may say that what in these investigations we were concerned with was the grammar of those words which describe what are called "mental activities": seeing, hearing, feeling, etc. And this comes to the same as saying that we are concerned with the grammar of 'phrases describing sense data'.

Page 70

Philosophers say it as a philosophical opinion or conviction that there are sense data. But to say that I *believe* that there are sense data comes to saying that I believe that an object may appear to be before our eyes even when it isn't. Now when one uses the word "sense datum", one should be clear about the peculiarity of its grammar. For the idea in introducing this expression was to model expressions referring to 'appearance' after expressions referring to

'reality'. It was said, e.g., that if two things *seem* to be equal, there *must* be two somethings which *are* equal. Which of course means nothing else but that we have decided to use such an expression as "the appearances of these two things are equal" synonymously with "these two things seem to be equal". Queerly enough, the introduction of this new phraseology has deluded people into thinking that they had discovered new entities, new elements of the structure of the world, as though to say "I believe that there are sense data" were similar to saying "I believe that matter consists of electrons". When we talk of the equality of appearances or sense data, we introduce a new usage of the word "equal". It is possible that the lengths A and B should appear to us to be equal, that B and C should appear to be equal, but that A and C do not appear to be equal. And in the new notation we shall have to say that though the appearance (sense datum) of A is equal to that of B and the appearance of B equal to that of C, the appearance of A is not equal to the appearance of C; which is all right if you don't mind using "equal" intransitively.

Page 70

Now the danger we are in when we adopt the sense datum notation is to forget the difference between the grammar of a statement about sense data and the grammar of an outwardly similar statement about physical objects. (From this point one might go on talking about the misunderstandings which find their expression in such sentences as: "We can never see an accurate circle", "All our sense data are vague". Also, this leads to the comparison of the grammar of "position", "motion", and "size" in Euclidean and in visual space.)

Page Break 71

There is, e.g., absolute position, absolute motion and size, in visual space.)

Page 71

Now we can make use of such an expression as "pointing to the *appearance* of a body" or "pointing to a visual sense datum". Roughly speaking, this sort of pointing comes to the same as sighting, say, along the barrel of a gun. Thus we may point and say: "This is the direction in which I see my image in the mirror". One can also use such an expression as "the appearance, or sense datum, of my finger points to the sense datum of the tree" and similar ones. From these cases of pointing, however, we must distinguish those of pointing in the direction a sound seems to come from, or of pointing to my forehead with dosed eyes, etc.

Page 71

Now when in the solipsistic way I say "*This* is what's really seen", I point before me and it is essential that I point *visually*. If I pointed sideways or behind me--as it were, to things which I don't see--the pointing would in this case be meaningless to me; it would not be pointing in the sense in which I wish to point. But this means that when I point before me saying "this is what's really seen", although I make the gesture of pointing, I don't point to one thing as opposed to another. This is as when travelling in a car and feeling in a hurry, I instinctively press against something in front of me as though I could push the car from inside.

Page 71

When it makes sense to say "I see this", or "this is seen", pointing to what I see, it also makes *sense* to say "I see this", or "this is seen", pointing to something I *don't* see. When I made my solipsist statement, I pointed, but I robbed the pointing of its sense by inseparably connecting that which points and that to which it points. I constructed a clock with all its wheels, etc., and in the end fastened the dial to the pointer and made it go round with it. And in this way the solipsist's "Only this is really seen" reminds us of a tautology.

Page 71

Of course one of the reasons why we are tempted to make our pseudo-statement is its similarity with the statement "I only see this", or "this is the region which I see", where I point to certain objects around me, as opposed to others, or in a certain direction in physical space (not in visual space), as opposed to other directions in physical space. And if, pointing in this sense, I say "this is what is really seen", one may answer me: "This is what *you*, L. W., see; but there is no objection to adopting a notation in which what we used to call 'things which L. W. sees' is called 'things really seen'". If, however, I believe that by pointing to that which in my grammar has no

Page Break 72

neighbour I can convey something to myself (if not to others), I make a mistake similar to that of thinking that the sentence "I am here" makes sense to me (and, by the way, is always true) under conditions different from those very special conditions under which it does make sense. E.g., when my voice and the direction from which I speak is recognized by another person. Again an important case where you can learn that a word has meaning by the particular use we make of it.--We are like people who think that pieces of wood shaped more or less like chess or draught pieces and standing on a chess board make a game, even if nothing has been said as to how they are to be used.

Page 72

To say "it approaches me" has sense, even when, physically speaking, nothing approaches my body; and in

the same way it makes sense to say, "it is here" or "it has reached me" when nothing has reached my body. And, on the other hand, "I am here" makes sense if my voice is recognized and heard to come from a particular place of common space. In the sentence "it is here" the 'here' was a here in visual space. Roughly speaking, it is the geometrical eye. The sentence "I am here", to make sense, must attract attention to a place in common space. (And there are several ways in which this sentence might be used.) The philosopher who thinks it makes sense to say to himself "I am here" takes the verbal expression from the sentence in which "here" is a place in common space and thinks of "here" as the here in visual space. He therefore really says something like "Here is here".

Page 72

I could, however, try to express my solipsism in a different way: I imagine that I and others draw pictures or write descriptions of what each of us sees. These descriptions are put before me. I point to the one which I have made and say: "Only this is (or was) really seen". That is, I am tempted to say: "Only this description has reality (visual reality) behind it". The others I might call--"blank descriptions". I could also express myself by saying: "*This* description only was derived from reality; only this was compared with reality". Now it has a clear meaning when we say that this picture or description is a projection, say, of this group of objects--the trees I look at--or that it has been derived from these objects. But we must look into the grammar of such a phrase as "this description is derived from my sense datum". What we are talking about is connected with that peculiar temptation to say: "I never know what the other really means by 'brown', or what he really sees when he (truthfully) says that he sees a brown object".--We could propose to one who says this to use

Page Break 73

two different words instead of the one word "brown"; one word *for his particular impression*, the other word with that meaning which other people besides himself can understand as well. If he thinks about this proposal he will see that there is something wrong in his conception of the meaning, function, of the word "brown" and others. He looks for a justification of his description where there is none. (Just as in the case when a man believes that the chain of reasons must be endless. Think of the justification by a general formula for performing mathematical operations; and of the question: Does this formula compel us to make use of it in this particular case as we do?) To say "I derive a description from visual reality" can't mean anything analogous to: "I derive a description from what I see here". I may, e.g., see a chart in which a coloured square is correlated to the word "brown", and also a patch of the same colour elsewhere; and I may say: "This chart shows me that I must use the word 'brown' for the description of this patch". This is how I may derive the word which is needed in my description. But it would be meaningless to say that I derive the word "brown" from the particular colour-impression which I receive.

Page 73

Let us now ask: "Can a human *body* have pain?" One is inclined to say: "How can the body have pain? The body in itself is something dead; a body isn't conscious!" And here again it is as though we looked into the nature of pain and saw that it lies in its nature that a material object can't have it. And it is as though we saw that what has pain must be an entity of a different nature from that of a material object; that, in fact, it must be of a mental nature. But to say that the ego is mental is like saying that the number 3 is of a mental or an immaterial nature, when we recognize that the numeral "3" isn't used as a sign for a physical object.

Page 73

On the other hand we can perfectly well adopt the expression "this body feels pain", and we shall then, just as usual, tell it to go to the doctor, to lie down, and even to remember that when the last time it had pains they were over in a day. "But wouldn't this form of expression at least be an indirect one?"--Is it using an indirect expression when we say "Write '3' for 'x' in this formula" instead of "Substitute 3 for x"? (Or on the other hand, is the first of these two expressions the only direct one, as some philosophers think?) One expression is no more direct than the other. The meaning of the expression depends entirely on how we go on using it. Let's not imagine the meaning as an occult connection the mind makes between

Page Break 74

a word and a thing, and that this connection *contains* the whole usage of a word as the seed might be said to contain the tree.

Page 74

The kernel of our proposition that that which has pains or sees or thinks is of a mental nature is only, that the word "I" in "I have pains" does not denote a particular body, for we can't substitute for "I" a description of a body.

Page Break 75

THE BROWN BOOK

Page 75

THE BROWN BOOK

I

AUGUSTINE, in describing his learning of language, says that he was taught to speak by learning the names of things. It is clear that whoever says this has in mind the way in which a child learns such words as "man", "sugar", "table", etc. He does not primarily think of such words as "today", "not", "but", "perhaps".

Suppose a man described a game of chess, without mentioning the existence and operations of the pawns. His description of the game as a natural phenomenon will be incomplete. On the other hand we may say that he has completely described a simpler game. In this sense we can say that Augustine's description of learning the language was correct for a simpler language than ours. Imagine this language:--

1). Its function is the communication between a builder A and his man B. B has to reach A building stones. There are cubes, bricks, slabs, beams, columns. The language consists of the words "cube", "brick", "slab", "column". A calls out one of these words, upon which B brings a stone of a certain shape. Let us imagine a society in which this is the only system of language. The child learns this language from the grown-ups by being trained to its use. I am using the word "trained" in a way strictly analogous to that in which we talk of an animal being trained to do certain things. It is done by means of example, reward, punishment, and suchlike. Part of this training is that we point to a building stone, direct the attention of the child towards it, and pronounce a word. I will call this procedure *demonstrative* teaching of words. In the actual use of this language, one man calls out the words as orders, the other acts according to them. But learning and teaching this language will contain this procedure: The child just 'names' things, that is, he pronounces the words of the language when the teacher points to the things. In fact, there will be a still simpler exercise: The child repeats words which the teacher pronounces.

(Note. Objection: The word "brick" in language 1) has not the meaning which it has in *our* language.--This is true if it means that

in our language there are usages of the word "brick" different from our usages of this word in language 1). But don't we sometimes use the word "brick!" in just this way? Or should we say that when we use it, it is an elliptical sentence, a shorthand for "Bring me a brick"? Is it right to say that if *we* say "brick!" we *mean* "Bring me a brick"? Why should I translate the expression "brick!" into the expression "Bring me a brick"? And if they are synonymous, why shouldn't I say: If he says "brick!" he means "brick!"...? Or: Why shouldn't he be able to mean just "brick!" if he is able to mean "Bring me a brick", unless you wish to assert that while he says aloud "brick!" he as a matter of fact always says in his mind, to himself, "Bring me a brick"? But what reason could we have to assert this? Suppose someone asked: If a man gives the order, "Bring me a brick", must he mean it as four words, or can't he mean it as one composite word synonymous with the one word "brick!"? One is tempted to answer: He *means* all four words if in his language he uses that sentence in contrast with other sentences in which these words are used, such as, for instance, "Take these two bricks away". But what if I asked "But how is his sentence contrasted with these others? Must he have thought them simultaneously, or shortly before or after, or is it sufficient that he should have one time learnt them, etc.?" When we have asked ourselves this question, it appears that it is irrelevant which of these alternatives is the case. And we are inclined to say that all that is really relevant is that these contrasts should exist in the system of language which he is using, and that they need not in any sense be present in his mind when he utters his sentence. Now compare this conclusion with our original question. When we asked it, we seemed to ask a question about the state of mind of the man who says the sentence, whereas the idea of meaning which we arrived at in the end was not that of a state of mind. We think of the meaning of signs sometimes as states of mind of the man using them, sometimes as the role which these signs are playing in a system of language. The connection between these two ideas is that the mental experiences which accompany the use of a sign undoubtedly are caused by our usage of the sign in a particular system of language. William James speaks of specific feelings accompanying the use of such words as "and", "if", "or". And there is no doubt that at least certain gestures are often connected with such words, as a collecting gesture with "and", and a dismissing gesture with "not". And there obviously are visual and muscular sensations connected with these gestures. On the other hand it is clear enough that these sensations do not

accompany every

Page Break 79

use of the word "not" and "and". If in some language the word "but" meant what "not" means in English, it is clear that we should not compare the meanings of these two words by comparing the sensations which they produce. Ask yourself what means we have of finding out the feelings which they produce in different people and on different occasions. Ask yourself: "When I said, 'Give me an apple *and* a pear, *and* leave the room', had I the same feeling when I pronounced the two words 'and'?" But we do not deny that the people who use the word "but" as "not" is used in English will, broadly speaking, have similar sensations accompanying the word "but" to those the English have when they use "not". And the word "but" in the two languages will on the whole be accompanied by different sets of experiences.)

Page 79

2). Let us now look at an extension of language 1). The builder's man knows by heart the series of words from one to ten. On being given the order, "Five slabs!", he goes to where the slabs are kept, says the words from one to five, takes up a slab for each word, and carries them to the builder. Here both the parties use the language by speaking the words. Learning the numerals by heart will be one of the essential features of learning this language. The use of the numerals will again be taught demonstratively. But now the same word, e.g., "three", will be taught by pointing either to slabs, or to bricks, or to columns, etc. And on the other hand, different numerals will be taught by pointing to groups of stones of the same shape.

Page 79

(Remark: We stressed the importance of learning the series of numerals by heart because there was no feature comparable to this in the learning of language 1). And this shows us that by introducing numerals we have introduced an entirely different *kind* of instrument into our language. The difference of kind is much more obvious when we contemplate such a simple example than when we look at our ordinary language with innumerable kinds of words all looking more or less alike when they stand in the dictionary.--

Page 79

What have the demonstrative explanations of the numerals in common with those of the words "slab", "column", etc., except a gesture and pronouncing the words? The way such a gesture is used in the two cases is different. This difference is blurred if one says, "In one case we point to a shape, in the other we point to a number". The difference becomes obvious and clear only when we contemplate a

Page Break 80

complete example (i.e., the example of a language completely worked out in detail.)

Page 80

3). Let us introduce a new instrument of communication,-a proper name. This is given to a particular object (a particular building stone) by pointing to it and pronouncing the name. If A calls the name, B brings the object. The demonstrative teaching of a proper name is different again from the demonstrative teaching in the cases 1) and 2).

Page 80

(Remark: This difference does not lie, however, in the act of pointing and pronouncing the word or in any mental act (meaning?) accompanying it, but in the role which the demonstration (pointing and pronouncing) plays in the whole training and in the use which is made of it in the practice of communication by means of this language. One might think that the difference could be described by saying that in the different cases we point to different kinds of objects. But suppose I point with my hand to a blue jersey. How does pointing to its colour differ from pointing to its shape?--We are inclined to say the difference is that we *mean* something different in the two cases. And 'meaning' here is to be some sort of process taking place while we point. What particularly tempts us to this view is that a man on being asked whether he pointed to the colour or the shape is, at least in most cases, able to answer this and to be certain that his answer is correct. If on the other hand, we look for two such characteristic mental acts as meaning the colour and meaning the shape, etc., we aren't able to find any, or at least none which must always accompany pointing to colour, pointing to shape, respectively. We have only a *rough* idea of what it means to concentrate one's attention on the colour as opposed to the shape, or vice versa. The difference, one might say, does not lie in the act of demonstration, but rather in the surrounding of that act in the use of the language.)

Page 80

4). On being ordered, "This slab!", B brings the slab to which A points. On being ordered, "Slab, there!", he carries a slab to the place indicated. Is the word "there" taught demonstratively? Yes and no! When a person is trained in the use of the word "there", the teacher will in training him make the pointing gesture and pronounce the word "there". But should we say that thereby he gives a place the name "there"? Remember that the pointing gesture

in this case is part of the practice of communication itself.

Page 80

(Remark: It has been suggested that such words as "there", "here", "now", "this" are the *'real proper names'* as opposed to what in ordinary

Page Break 81

life we call proper names, and, in the view I am referring to, can only be called so crudely. There is a widespread tendency to regard what in ordinary life is called a proper name only as a rough approximation of what ideally could be called so. Compare Russell's idea of the 'individual'. He talks of individuals as the ultimate constituents of reality, but says that it is difficult to say which things are individuals. The idea is that further analysis has to reveal this. We, on the other hand, introduced the idea of a proper name in a language in which it was applied to what in ordinary life we call "objects", "things" ("building stones").

Page 81

---"What does the word 'exactness' mean? Is it real exactness if you are supposed to come to tea at 4.30 and come when a good clock strikes 4.30? Or would it only be exactness if you began to open the door at the moment the clock began to strike? But how is this moment to be defined and how is 'beginning to open the door' to be defined? Would it be correct to say, 'It is difficult to say what real exactness is, for all we know is only rough approximations?'"

Page 81

5). Questions and answers: A asks, "How many slabs?" B counts them and answers with the numeral.

Page 81

Systems of communication as for instance 1), 2), 3), 4), 5) we shall call "language games". They are more or less akin to what in ordinary language we call games. Children are taught their native language by means of such games, and here they even have the entertaining character of games. We are not, however, regarding the language games which we describe as incomplete parts of a language, but as languages complete in themselves, as complete systems of human communication. To keep this point of view in mind, it very often is useful to imagine such a simple language to be the entire system of communication of a tribe in a primitive state of society. Think of primitive arithmetics of such tribes.

Page 81

When the boy or grown-up learns what one might call special technical languages, e.g., the use of charts and diagrams, descriptive geometry, chemical symbolism, etc., he learns more language games. (Remark: The picture we have of the language of the grown-up is that of a nebulous mass of language, his mother tongue, surrounded by discrete and more or less clear-cut language games, the technical languages.)

Page 81

6). Asking for the name: we introduce new forms of building stones. B points to one of them and asks, "What is this?"; A answers,

Page Break 82

"This is a...". Later on A calls out this new word, say "arch", and B brings the stone. The words, "This is..." together with the pointing gesture we shall call ostensive explanation or ostensive definition. In case 6) a generic name was explained, in actual fact, as the name of a shape. But we can ask analogously for the proper name of a particular object, for the name of a colour, of a numeral, of a direction.

Page 82

(Remark: Our use of expressions like "names of numbers", "names of colours", "names of materials", "names of nations" may spring from two different sources. One is that we might imagine the functions of proper names, numerals, words for colours, etc., to be much more alike than they actually are. If we do so we are tempted to think that the function of every word is more or less like the function of a proper name of a person, or such generic names as "table", "chair", "door", etc. The second source is this, that if we see how fundamentally different the functions of such words as "table", "chair", etc., are from those of proper names, and how different from either the functions of, say, the names of colours, we see no reason why we shouldn't speak of names of numbers or names of directions either, not by way of saying some such thing as "numbers and directions are just different forms of objects", but rather by way of stressing the analogy which lies in the lack of analogy between the functions of the words "chair" and "Jack" on the one hand, and "east" and "Jack" on the other hand.)

Page 82

7). B has a table in which written signs are placed opposite to pictures of objects (say, a table, a chair, a tea-cup, etc.). A writes one of the signs, B looks for it in the table, looks or points with his finger from the written sign to the picture opposite, and fetches the object which the picture represents.

Let us now look at the different kinds of signs which we have introduced. First let us distinguish between sentences and words. A sentence†1 I will call every complete sign in a language game, its constituent signs are words. (This is merely a rough and general remark about the way I will use the words "proposition"†1 and "word".) A proposition may consist of only one word. In 1) the signs "brick!", "column!" are the sentences. In 2) a sentence consists of two words. According to the role which propositions play in a language game, we distinguish between orders, questions, explanations, descriptions, and so on.

8). If in a language game similar to 1) A calls out an order: "slab, column, brick!" which is obeyed by B by bringing a slab, a column and a brick, we might here talk of three propositions, or of one only. If, on the other hand,

9). the order of words shows B the order in which to bring the building stones, we shall say that A calls out a proposition consisting of three words. If the command in this case took the form, "Slab, then column, then brick!" we should say that it consisted of four words (not of five). Amongst the words we see groups of words with similar functions. We can easily see a similarity in the use of the words "one," "two", "three", etc. and again one in the use of "slab", "column" and "brick", etc., and thus we distinguish parts of speech. In 8) all the words of the proposition belonged to the same part of speech.

10). The order in which B had to bring the stones in 9) could have been indicated by the use of the ordinals thus: "Second, column; first, slab; third, brick!". Here we have a case in which what was the function of the order of words in one language game is the function of particular words in another.

Reflections such as the preceding will show us the infinite variety of the functions of words in propositions, and it is curious to compare what we see in our examples with the simple and rigid rules which logicians give for the construction of propositions. If we group words together according to the similarity of their functions, thus distinguishing parts of speech, it is easy to see that many different ways of classification can be adopted. We could indeed easily imagine a reason for not classing the word "one" together with "two", "three", etc., as follows:

11). Consider this variation of our language game 2). Instead of calling out, "One slab!", "One cube!", etc., A just calls "Slab!", "Cube!", etc., the use of the other numerals being as described in 2). Suppose that a man accustomed to this form 11) of communication was introduced to the use of the word "one" as described in 2). We can easily imagine that he would refuse to classify "one" with the numerals "2" "3" etc.

(Remark: Think of the reasons for and against classifying 'o' with the other cardinals. "Are black and white colours?" In which cases would you be inclined to say so and which not?--Words can in

many ways be compared to chess men. Think of the several ways of distinguishing different kinds of pieces in the game of chess (e.g., pawns and 'officers').

Remember the phrase, "two or more".)

It is natural for us to call gestures, as those employed in 4), or pictures as in 7), elements or instruments of language. (We talk sometimes of a language of gestures.) The pictures in 7) and other instruments of language which have a similar function I shall call patterns. (This explanation, as others which we have given, is vague, and meant to be vague.) We may say that words and patterns have different kinds of functions. When we make use of a pattern we compare something with it, e.g., a chair with the picture of a chair. We did not compare a slab with the word "slab". In introducing the distinction, 'word/pattern', the idea was not to set up a final logical duality. We have only singled out two characteristic kinds of instruments from the variety of instruments in our language. We shall call "one", "two", "three", etc., words. If instead of these signs we used "--", "-- --", "-- -- --", "-- -- -- --", we might call these patterns. Suppose in a language the numerals were "one", "one one", "one one one", etc., should we call "one" a word or a pattern? The same element may in one place be used as word and in another as pattern. A circle might be the name for an ellipse, or on the other hand a pattern with which the ellipse is to be compared by a particular method of projection. Consider also these two systems of expression:

12). A gives B an order consisting of two written symbols, the first an irregularly shaped patch of a certain colour, say green, the second the drawn outline of a geometrical figure, say a circle. B brings an object of this outline and that colour, say a circular green object.

13). A gives B an order consisting of one symbol, a geometrical figure painted a particular colour, say a green circle. B brings him a green circular object. In 12) patterns correspond to our names of colours and other patterns to our names of shape. The symbols in 13) cannot be regarded as combinations of two such elements. A word in inverted commas can be called a pattern. Thus in the sentence "He said 'Go to hell'", "Go to hell" is a pattern of what he said. Compare these cases: a) Someone says "I whistled..." (whistling a tune);

b) Someone writes, "I whistled

". An onomatopoeic

word like "rustling" may be called a pattern. We call a very great variety of processes "comparing an object with a pattern". We comprise many kinds of symbols under the name "pattern". In 7) B compares a picture in the table with the objects he has before him. But what does comparing a picture with the object consist in? Suppose the table showed: a) a picture of a hammer, of pincers, of a saw, of a chisel; b) on the other hand, pictures of twenty different kinds of butterflies. Imagine what the comparison in these two cases would consist in, and note the difference. Compare with these cases a third case c) where the pictures in the table represent building stones drawn to scale, and the comparing has to be done with ruler and compasses. Suppose that B's task is to bring a piece of cloth of the colour of the sample. How are the colours of sample and cloth to be compared? Imagine a series of different cases:

14). A shows the sample to B, upon which B goes and fetches the material 'from memory'.

15). A gives B the sample, B looks from the sample to the materials on the shelves from which he has to choose.

16). B lays the sample on each bolt of material and chooses that one which he can't distinguish from the sample, for which the difference between the sample and the material seems to vanish.

17). Imagine on the other hand that the order has been, "Bring a material slightly darker than this sample". In 14) I said that B fetches the material 'from memory', which is using a common form of expression. But what might happen in such a case of comparing 'from memory' is of the greatest variety. Imagine a few instances:

14a). B has a memory image before his mind's eye when he goes for the material. He alternately looks at materials and recalls his image. He goes through this process with, say, five of the bolts, in some instances saying to himself, "Too dark", in some instances saying to himself, "Too light". At the fifth bolt he stops, says, "That's it" and takes it from the shelf.

14b). No memory image is before B's eye. He looks at four bolts, shaking his head each time, feeling some sort of mental tension. On reaching the fifth bolt, this tension relaxes, he nods his head, and takes the bolt down.

14c). B goes to the shelf without a memory image, looks at five bolts one after the other, takes the fifth bolt from the shelf.

'But this can't be all comparing consists in.'

When we call these three preceding cases, cases of comparing from memory, we feel that their description is in a sense unsatisfactory, or incomplete. We are inclined to say that the description has left out the essential feature of such a process and given us accessory features only. The essential feature it seems would be what one might call a specific experience of comparing and of recognizing. Now it is queer that on closely looking at cases of comparing,

it is very easy to see a great number of activities and states of mind, all *more or less* characteristic of the act of comparing. This in fact is so, whether we speak of comparing from memory or of comparing by means of a sample before our eyes. We know a *vast* number of such processes, processes similar to each other in a vast number of different ways. We hold pieces whose colours we want to compare together or near each other for a longer or shorter period, look at them alternately or simultaneously, place them under different lights, say different things while we do so, have memory images, feelings of tension and relaxation, satisfaction and dissatisfaction, the various feelings of strain in and around our eyes accompanying prolonged gazing at the same object, and all possible combinations of these and many other experiences. The more such cases we observe and the closer we look at them, the more doubtful we feel about finding one particular mental experience characteristic of comparing. In fact, if after you had scrutinized a number of such *closely*, I admitted that there existed a peculiar mental experience which you might call the experience of comparing, and that if you insisted, I should be willing to adopt the word "comparing" only for cases in which this peculiar feeling had occurred, you would now feel that the assumption of such a peculiar experience had lost its point, because this experience was placed side by side with a vast number of other experiences which after we have scrutinized the cases seems to be that which really constitutes what connects all the cases of comparing. For the 'specific experience' we had been looking for was meant to have played the role which has been assumed by the mass of experiences revealed to us by our scrutiny: We never wanted the specific experience to be just one among a number of *more or less* characteristic experiences. (One might say that there are two ways of looking at this matter, one as it were, at dose quarters, the other as though from a distance and through the medium of a peculiar atmosphere.) In fact we have found that the use which we really make of the word "comparing" is different from that which looking at it

Page Break 87

from far away we were led to expect. We find that what connects all the cases of comparing is a vast number of overlapping similarities, and as soon as we see this, we feel no longer compelled to say that there must be some one feature common to them all. What ties the ship to the wharf is a rope, and the rope consists of fibres, but it does not get its strength from any fibre which runs through it from one end to the other, but from the fact that there is a vast number of fibres overlapping.

Page 87

'But surely in case 14c) B acted entirely automatically. If all that happened was really what was described there, he did not know why he chose the bolt he did choose. He had no reason for choosing it. If he chose the right one, he did it as a machine might have done it'. Our first answer is that we did not deny that B in case 14c) had what we should call a personal experience, for we did not say that he didn't see the materials from which he chose or that which he chose, nor that he didn't have muscular and tactile sensations and suchlike while he did it. Now what would such a reason which justified his choice and made it non-automatic be like? (i.e.: What do we *imagine* it to be like?) I suppose we should say that the opposite of automatic comparing, as it were, the ideal case of conscious comparing, was that of having a clear memory image before our mind's eye or of seeing a real sample and of having a specific feeling of not being able to distinguish in a particular way between these samples and the material chosen. I suppose that this peculiar sensation is the reason, the justification, for the choice. This specific feeling, one might say, connects the two experiences of seeing the sample, on the one hand, and the material on the other. But if so, what connects this specific experience with either? We don't deny that such an experience might intervene. But looking at it as we did just now, the distinction between automatic and non-automatic appears no longer clear-cut and final as it did at first. We don't mean that this distinction loses its practical value in particular cases, e.g., if asked under particular circumstances "Did you take this bolt from the shelf automatically, or did you think about it?", we may be justified in saying that we did not act automatically and give as an explanation that we had looked at the material carefully, had tried to recall the memory image of the pattern, and had uttered to ourselves doubts and decisions. This may *in the particular case* be taken to distinguish automatic from non-automatic. In another case, however, we may distinguish between an automatic

Page Break 88

and a non-automatic way of the appearance of a memory image, and so on.

Page 88

If our case 14c) troubles you, you may be inclined to say: "But *why* did he bring just this bolt of material? How has he recognized it as the right one? What by?"--If you ask 'why', do you ask for the cause or for the reason? If for the cause, it is easy enough to think up a physiological or psychological hypothesis which explains this choice under the given conditions. It is the task of the experimental sciences to test such hypotheses. If on the other hand you ask for a reason the answer is, "There need not have been a reason for the choice. A reason is a step preceding the step of the choice. But why should every step be preceded by another one?"

'But then B didn't really *recognize* the material as the right one. You needn't reckon 14c) among the cases of recognizing, but if you have become aware of the fact that the processes which we call processes of recognition form a vast family with overlapping similarities, you will probably feel not disinclined to include 14c) in this family, too.--'But doesn't B in this case lack the criterion by which he can recognize the material? In 14a), e.g., he had the memory image and he recognized the material he looked for by its agreement with the image.--But had he also a picture of this agreement before him, a picture with which he could compare the agreement between the pattern and the bolt to see whether it was the right one? And, on the other hand, couldn't he have been given such a picture? Suppose, e.g., that A wished B to remember that what was wanted was a bolt exactly like the sample, not, as perhaps in other cases, a material slightly darker than the pattern. Couldn't A in this case have given to B an example of the agreement required by giving him two pieces of the same colour (e.g., as a kind of reminder)? Is any such link between the order and its execution necessarily the last one?--And if you say that in 14b) at least he had the relaxing of the tension by which to recognize the right material, had he to have an image of this relaxation about him to recognize it as that by which the right material was to be recognized?--

'But supposing B brings the bolt, as in 14c), and on comparing it with the pattern it turns out to be the wrong one?--But couldn't that have happened in all the other cases as well? Suppose in 14a) the bolt which B brought back was found not to match with the pattern. Wouldn't we in some such cases say that his memory image had changed, in others that the pattern or the material had changed, in

others again that the light had changed? It is not difficult to invent cases, imagine circumstances, in which each of these judgments would be made.--'But isn't there after all an essential difference between the cases 14a) and 14c)?--Certainly! Just that pointed out in the description of these cases.--

In 1) B learnt to bring a building stone on hearing the word "column!" called out. We could imagine what happened in such a case to be this: In B's mind the word called out brought up an image of a column, say; the training had, as we should say, established this association. B takes up that building stone which conforms to his image.--But was this *necessarily* what happened? If the training could bring it about that the idea or image-automatically--arose in B's mind, why shouldn't it bring about B's *actions* without the intervention of an image? This would only come to a slight variation of the associative mechanism. Bear in mind that the image which is brought up by the word is not arrived at by a rational process (but if it is, this only pushes our argument further back), but that this case is strictly comparable with that of a mechanism in which a button is pressed and an indicator plate appears. In fact this sort of mechanism can be used instead of that of association.

Mental images of colours, shapes, sounds, etc., etc., which play a role in communication by means of language we put in the same category with patches of colour actually seen, sounds heard.

18). The object of the training in the use of tables (as in 7)) may be not only to teach the use of one particular table, but it may be to enable the pupil to use or construct himself tables with new co-ordinations of written signs and pictures. Suppose the first table a person was trained to use contained the four words "hammer", "pincers", "saw", "chisel" and the corresponding pictures. We might now add the picture of another object which the pupil had before him, say of a plane, and correlate with it the word "plane". We shall make the correlation between this new picture and word as similar as possible to the correlations in the previous table. Thus we might add the new word and picture on the same sheet, and place the new word under the previous words and the new picture under the previous pictures. The pupil will now be encouraged to make use of the new picture and word without the special training which we gave him when we taught him to use the first table. These acts of encouragement will be of various kinds, and many such acts will only be possible if

the pupil responds, and responds in a particular way. Imagine the gestures, sounds, etc., of encouragement you use when you teach a dog to retrieve. Imagine on the other hand, that you tried to teach a cat to retrieve. As the cat will not respond to your encouragement, most of the acts of encouragement which you performed when you trained the dog are here out of the question.

19). The pupil could also be trained to give things names of his own invention and to bring the objects when the names are called. He is, e.g., presented with a table on which he finds pictures of objects around him on one side

and blank spaces on the other, and he plays the game by writing signs of his own invention opposite the pictures and reacting in the previous way when these signs are used as orders. Or else

Page 90

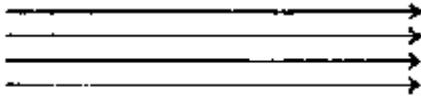

20). the game may consist in B's constructing a table and obeying orders given in terms of this table. When the use of a table is taught, and the table consists, say, of two vertical columns, the left hand one containing the names, the right hand one the pictures, a name and a picture being correlated by standing on a horizontal line, an important feature of the training may be that which makes the pupil slide his finger from left to right, as it were the training to draw a series of horizontal lines, one below the other. Such training may help to make the transition from the first table to the new item.

Page 90

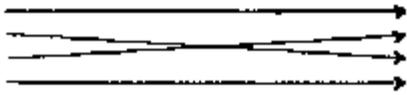

Tables, ostensive definitions, and similar instruments I shall call rules, in accordance with ordinary usage. The use of a rule can be explained by a further rule.

Page 90

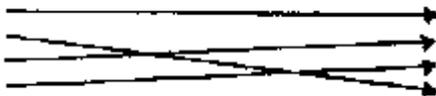

21). Consider this example: We introduce different ways of reading tables. Each table consists of two columns of words and pictures, as above. In some cases they are to be read horizontally from left to right, i.e., according to the scheme:

In others according to such schemes as:

or:

etc.

Page Break 91

Schemes of this kind can be adjoined to our tables, as rules for reading them. Could not these rules again be explained by further rules? Certainly. On the other hand, is a rule incompletely explained if no rule for its usage has been given?

Page 91

We introduce into our language games the endless series of numerals. But how is this done? Obviously the analogy between this process and that of introducing a series of twenty numerals is not the same as that between introducing a series of twenty numerals and introducing a series of ten numerals. Suppose that our game was like 2) but played with the endless series of numerals. The difference between it and 2) would not be just that more numerals were used. That is to say, suppose that as a matter of fact in playing the game we had actually made use of, say, 155 numerals, the game we play would not be that which could be described by saying that we played the game 2), only with 155 instead of 10 numerals. But what does the difference consist in? (The difference would seem to be almost one of the spirit in which the games are played.) The difference between games can lie, say, in the number of the counters used, in the number of squares of the playing board, or in the fact that we use squares in one case and hexagons in the other, and suchlike. Now the difference between the finite and infinite game does not seem to lie in the material tools of the game; for we should be inclined to say that infinity can't be expressed in them, that is, that we can only conceive of it in our thoughts, and hence that it is in these thoughts that the finite and infinite game must be distinguished. (It is queer though that these thoughts should be capable of being expressed in signs.)

Page 91

Let us consider two games. They are both played with cards carrying numbers, and the highest number takes the trick.

Page 91

22). One game is played with a fixed number of such cards, say 32. In the other game we are under certain circumstances allowed to increase the number of cards to as many as we like, by cutting pieces of paper and writing numbers on them. We will call the first of these games bounded, the second unbounded. Suppose a hand of the second game was played and the number of cards actually used was 32. What is the difference in this case between

playing a hand *a*) of the unbounded game and playing a hand *b*) of the bounded game?

Page 91

The difference will not be that between a hand of a bounded game with 32 cards and a hand of a bounded game with a greater number of cards. The number of cards used was, we said, the same. But there

Page Break 92

will be differences of another kind, e.g., the bounded game is played with a normal pack of cards, the unbounded game with a large supply of blank cards and pencils. The unbounded game is opened with the question, "How high shall we go?" If the players look up the rules of this game in a book of rules, they will find the phrase "and so on" or "and so on *ad inf.*" at the end of certain series of rules. So the difference between the two hands *a*) and *b*) lies in the tools we use, though admittedly not in the cards they are played with. But this difference seems trivial and not the essential difference between the games. We feel that there must be a big and essential difference somewhere. But if you look closely at what happens when the hands are played, you find that you can only detect a number of differences in details, each of which would seem inessential. The acts, e.g., of dealing and playing the cards *may* in both cases be identical. In the course of playing the hand *a*), the players may have considered making up more cards, and again discarded the idea. But what was it like to consider this? It could be some such process as saying to themselves or aloud "I wonder whether I should make up another card". Again, no such consideration may have entered the minds of the players. It is possible that the whole difference in the events of a hand of the bounded, and a hand of the unbounded, game lay in what was said before the game started, e.g., "Let's play the bounded game".

Page 92

'But isn't it correct to say that hands of the two different games belong to two different systems?' Certainly. Only the facts which we are referring to by saying that they belong to different systems are much more complex than we might expect them to be.

Page 92

Let us now compare language games of which we should say that they are played with a limited set of numerals, with language games of which we should say that they are played with the endless series of numerals.

Page 92

23). Like 2) A orders B to bring him a number of building stones. The numerals are the signs "1", "2",..... "9", each written on a card. A has a set of these cards and gives B the order by showing him one of the set and calling out one of the words, "slab", "column", etc.

Page 92

24). Like 23), only there is no set of indexed cards. The series of numerals 1 ... 9 is learned by heart. The numerals are called out in the orders, and the child learns them by word of mouth.

Page Break 93

Page 93

25). An abacus is used. A sets the abacus, gives it to B, B goes with it to where the slabs lie, etc.

Page 93

26). B is to count the slabs in a heap. He does it with an abacus, the abacus has twenty beads. There are never more than 20 slabs in a heap. B sets the abacus for the heap in question and shows A the abacus thus set.

Page 93

27). Like 26). The abacus has 20 small beads and one large one. if the heap contains more than 20 slabs, the large bead is moved. (So the large bead in some way corresponds to the word "many".)

Page 93

28). Like 26). If the heap contains n slabs, n being more than 20 but less than 40, B moves $n-20$ beads, shows A the abacus thus set and claps his hands once.

Page 93

29). A and B use the numerals of the decimal system (written or spoken) up to 20. The child learning this language learns these numerals by heart, as in 2).

Page 93
